R. N. B.	ROBERT NISBET BAIN. Assistant Librarian, British Museum, 1883–1909. Author of *Scandinavia. The Political History of Denmark, Norway and Sweden, 1513–1900; The First Romanovs, 1613–1725, Slavonic Europe: The Political History of Poland and Russia from 1469–1796*, etc.	Toll, Johan Kristoffer; Tolstoy, Petr Andreevich; Tordenskjold, Peder (*in part*); Torstensson; Valdemar I. (*in part*); Valdemar II. (*in part*); Valdemar IV.
R. Ry.	ROBERT RIDGWAY, A M , M.S Chief Engineer, Board of Transport, New York City Past-President, American Society of Civil Engineers.	Tunnel.
R. S. M.	R. S. MORRELL, M.A , PH.D., F.I C Research Chemist at Messrs Mander Bros , Ltd., Wolverhampton Formerly Fellow of Gonville and Caius College, Cambridge	Ultramarine; Varnishes, Chemistry of (*in part*)
R. S. Pn.	RALPH SNEYD PEARSON, C.E.I , F L S. Director, Forest Product Research Laboratory, Princes Risborough, Bucks Formerly Forest Economist at the Forest Research Institute, Dehra Dun, India	Timber Preservation.
R. U. S.	R U. SAYCE, M A Lecturer in Material Culture and Physical Anthropology in the University of Cambridge Formerly Lecturer in Geology and Geography, University College, Natal	Transvaal (*in part*)
S. Ca.	STANLEY CASSON, M.A , F.S.A. Fellow of New College and Reader in Classical Archaeology in the University of Oxford Corresponding Member of the German Archaeological Institute Sometime Assistant Director at the British School at Athens, and Director of the Excavations carried out by the British Academy at Constantinople Author of *Macedonia, Thrace and Illyria, Ancient Greece*	Turkey (*in part*).
S. Che.	SHELDON CHENEY, A B. Founder of the *Theatre Arts Magazine* and Editor until 1921 Author of *The Art of the Theatre, Stage Decoration*, etc.	Theatre (*in part*)
S. C. I.	S C ISAACS, B A., LL B. Of the Inner Temple and Midland Circuit, Barrister-at-Law Jardine Student of the Inner Temple Author of *The Laws Relating to Theatres, Music Halls and Other Public Entertainments*	Theatres, Law Relating to (*in part*)
S. H. M.	SYDNEY HERBERT MELLONE, M A , D.SC. Lecturer, Manchester College, Oxford Examiner in Philosophy, Universities of St Andrews, 1899 1902, London, 1902–6, Edinburgh, 1907–10, in Psychology, Edinburgh, 1913–6 Lecturer in the University of Manchester, 1911–21 Author of *The New Testament and Modern Life; The Price of Progress and Other Essays, The Apocrypha, Its Story and Message*, etc	Tithes; Unitarianism (*in part*)
S. L. C.	STEVENSON LYLE CUMMINGS, C.B., C M G., M D , LL.D. Colonel, Army Medical Service (retired) David Davies Professor of Tuberculosis, University College of South Wales and Monmouthshire	Tuberculosis (*in part*).
S. Le.	STUART LEWIS, A M., PH D Professor of Law, New Jersey Law School Author of *An Outline of American Federal Government*	Township.
S. Mo.	STANLEY MORISON Editor of *The Fleuron*, London Typographical Adviser to the Lanston Monotype Corporation, London, to the University Press, Cambridge, and formerly to Doubleday Page and Co , New York Author of *Four Centuries of Fine Printing, German Gothic Incunabula*, etc	Typography.
S. S. R.	SAMUEL S. ROBINSON Rear-Admiral, United States Navy Fleet Superintendent, United States Naval Academy.	United States Naval Academy.
T. A.	THOMAS ASHBY, D.LITT., F.B A., F S.A , HON.A R.I.B.A. Formerly Director of the British School at Rome. Author of *Turner's Visions of Rome, The Roman Campagna in Classical Times; Roman Architecture.* Revised and completed for Press a *Topographical Dictionary of Ancient Rome* (by the late Prof J. B. Plattner). Author of numerous archaeological articles	Tibur; Trasimenus, Lake; Trebia; Turin (*in part*), Tuscany (*in part*); Tusculum; Tyndaris; Umbria.
T. A. A.	THOMAS ANDREW ARCHER. Author of *The Crusade of Richard I.*; etc.	Ursula, St. (*in part*)
T. Ad.	THOMAS ADAMS Director of Plans and Surveys of Regional Plan of New York. Sometime Town Planning Adviser to the Commission of Conservation of Canada and Adviser to Cabinet of Federal Government on Post-War Housing Schemes First Town Planning Inspector of Local Government Board (now Ministry of Health) of England and Wales, 1909 14	Town and City Planning.
T. E. M.	THOMAS EUGENE MITTEN. President of Mitten Management, Incorporated. Operator of the transportation systems of Philadelphia and Buffalo.	Tramway (*in part*).
T. F. H.	TALBOT F. HAMLIN, B.A., B.ARCH. Instructor in the History of Architecture, Columbia University, New York. Chairman, City Plan Committee of the Merchants' Association, New York. Author of *The Enjoyment of Architecture; The American Spirit in Architecture.*	Tile; Tomb; Tower; Tracery; Transept; Transom; Triforium; Triumphal Arch; Tudor Period.

T. H.	THOMAS HODGKIN, B.A. Author of *Italy and Her Invaders; Theodoric the Goth, Life of Charles the Great* See the biographical article: HODGKIN, THOMAS	Vandals (*in part*).
T. H. W.	THOMAS HUDSON WILLIAMS, M.A., D.LITT. Professor of Greek in the University College of North Wales Author of *The Elegies of Theognis, Welsh Handbook to New Testament Greek,* etc.	Theognis of Megara.
T. J. E.	MAJOR T. J. EDWARDS. Secretary to the Honours and Distinctions Committee, War Office. Author of *The Perforated Map, The Non-Commissioned Officer's Guide to Promotion in the Infantry*	Uniforms (*in part*).
T. L. H.	SIR THOMAS LITTLE HEATH, K.C.B., K.C.V.O., SC.D., F.R.S. Assistant Secretary to the Treasury, 1907–13 Hon. Fellow of Trinity College, Cambridge Author of the *Thirteen Books of Euclid's Elements, A History of Greek Mathematics,* etc.	Theodosius.
T. M. Li.	REV. THOMAS MARTIN LINDSAY, LL.D., D D. Late Principal and Professor of the United Free Church College, Glasgow Author of *History of the Reformation; Life of Luther,* etc	Thomas À. Kempis.
T. S.	THOMAS SECCOMBE, M.A. Late of Balliol College, Oxford, and Lecturer in History, East London and Birkbeck Colleges, University of London Stanhope Prizeman, Oxford, 1887 Assistant Editor of *Dictionary of National Biography,* 1891–1901. Author of *The Age of Johnson,* etc	Tichborne Claimant, The.
V. M. Cu.	VICTOR M CUTTER, B.L , M.C S. President, United Fruit Company, Boston, Mass.	United Fruit Company.
V. W. B.	VAN WYCK BROOKS, A B. Author of *America's Coming of Age; The World of H G Wells, The Pilgrimage of Henry James, The Ordeal of Mark Twain*	Twain, Mark.
W. A. B.	WYNDHAM A BEWES Of Lincoln's Inn, Barrister-at-Law. Hon Secretary of the International Law Association and of the Grotius Society.	Trust and Trustees (*in part*)
W. A. G.	WILLIAM A GANOE, M A Major, United States Army. Executive, Historical Section, American War College, Washington Author of *The English of Military Communications, The History of the United States Army.*	United States of America (*in part*)
W. A. Or.	WILLIAM A. ORTON. Director and General Manager, Tropical Plant Research Foundation, Washington	Tropical Agriculture.
W. A. P.	W. ALISON PHILLIPS, M A. Lecky Professor of Modern History, Dublin University. Contributor to *The Cambridge Modern History,* etc.	Treaties (*in part*)
W. B. Pa.	WILLIAM BARCLAY PARSONS, C E., LL D., Sc D Of the firm of Parsons, Klapp, Brinckerhoff and Douglas, Engineers, New York	Traffic and Traffic Regulations (*in part*); United States of America (*in part*).
W. D.	W DALLIMORE Keeper of Museums, Royal Botanic Gardens, Kew.	Tree Planting.
W. de B. H.	W DE BRACY HERBERT. Barrister-at-Law. Recorder of Newcastle-under-Lyme.	Treason (*in part*).
W. D. M.	WILLIAM DILLER MATTHEW, A.M , PH D , F.R S. Professor of Palaeontology and Director of Museum of Palaeontology, University of California. Author of various scientific treatises on fossil vertebrates	Toxodontia; Tylopoda.
W. E. A.	W E. ARMSTRONG. Assistant Professor of History at Earlham College, Richmond, Indiana	Totemism.
W. E. E.	W ELMER EKBLAW, M.A , PH.D Clark University, Worcester, Mass Assistant Editor, *Economic Geography* Special field of research—agricultural geography and arctic geography	United States of America (*in part*); Uxmal.
W. E. W.	W. E. WORNUM, B.Sc , A I.C. Technical and Research Chemist, Mander Bros , Ltd , Wolverhampton	Varnishes, Chemistry of (*in part*)
W. F. C.	WILLIAM FEILDEN CRAIES, M.A Late Barrister-at-Law, Inner Temple, and Lecturer on Criminal Law, King's College, London Editor of *Archbold's Criminal Pleading.*	Trade Marks (*in part*); Treason (*in part*).
W. F. D.	WALTER F. DODD, B.S., PH.D. Professor of Law, Yale University. Author of *Modern Constitutions; State Government.*	United States of America (*in part*).
W. Ga.	W GARSTANG, M A , D.Sc. Professor of Zoology, University of Leeds.	Tunicata.
W. H. Cl.	SIR WILLIAM HENRY CLARK, K.C.S.I., C.M.G., M.A High Commissioner in Canada for H M. Government in Great Britain. Comptroller-General of Department of Overseas Trade, 1917–28 Sometime Private Secretary at Board of Trade.	Trade Facilities.
W. H. P.	WALLACE H. PAULL. Technical Director of the Dunlop Rubber Co., Ltd , Birmingham, England.	Tyre.
W. H. S.	W HOWARD SADGROVE. Managing Director of Messrs. Sadgrove & Co., Ltd., Wholesale Furniture Manufacturers and Upholsterers, London.	Upholstery.

W. K. G.	WILLIAM K GREGORY, A.M., PH.D. Curator of the Departments of Comparative Anatomy and Ichthyology, American Museum of Natural History Professor of Vertebrate Palaeontology, Columbia University Author of *The Orders of Mammals*, etc	**Ungulata.**

THE ENCYCLOPÆDIA BRITANNICA

FOURTEENTH EDITION

VOLUME 22

TEXTILES TO VASCULAR SYSTEM

TEXTILES, the general name applied to the products of the weaver, the derivation of the word being from L. *texere*, to weave. For details *see* the articles under the various fibre headings, such as wool, cotton, silk, flax, jute, artificial silk and cellulose. *See* also SPINNING, WEAVING, CARDING, COMBING, FINISHING, DYEING, etc

TEXTILES AND EMBROIDERIES. Inasmuch as "textile" is a general term for all woven fabrics, and "embroidery" is the ornamentation thereof, it is well, in treating the history and development of the two subjects, to consider the two together The following sections are made· (1) *Europe and the Near East;* (2) *India;* (3) *The Far East.*

EUROPE AND THE NEAR EAST

Weaving was one of the earliest crafts, if not actually the earliest, practised by primitive mankind. Whether its invention goes back to a time when men were still nomads we cannot say, but at the stage of human development when lake-dwellings were erected threads were already woven into fabrics Implements for preparing the threads, and fragments of the fabrics themselves, have been found on such sites There is nothing to show that these stuffs were enriched with a pattern. The first attempts in that direction were probably made by the application of pigments or some sort of simple embroidery

The East is the natural home of patterned fabrics. The Chinese were the first cultivators of the silkworm for the textile threads it provides Recent excavations have shown that the valley of the Indus is the native home of the variety of the cotton plant still cultivated for weaving purposes. To the valley of the Nile has long been attributed the origin of linen weaving To one of these regions we should naturally look for the first patterned stuffs

Egypt and the Crimea.—The earliest known to exist are some linen stuffs from Egypt of the 15th century B.C. (*see* TAPESTRY). In them pattern-weaving has already reached a highly developed stage, and far earlier examples may only await the spade of the excavator. For the thousand years which follow we again have nothing in the way of patterned stuffs The next in chronological sequence come from the graves of Greek colonists in the Crimea, and are now in the Hermitage museum at Leningrad. They are mostly of wool, with woven, painted or embroidered ornamentation. The patterns include figures on horse-back, warriors, goddesses, chariots, animals, birds, vines, flowers, anthemion ornament, scrolls, diapers and stripes A few fragments are of linen; there is one silk stuff of uncertain age, and some of the embroidery is in gold thread For the most part the graves are of the 4th and 3rd centuries B C, but some are earlier and others later. Stuffs of late Graeco-Roman times from the burying-grounds of Egypt share the common features of Graeco-Roman art then spread around the shores of the Mediterranean Linen is the principal material, but coloured woollen threads, particularly in purple, are generally used for the ornamentation, and as time passes the whole fabric is sometimes of wool

For early Christian textiles we are still dependent upon Egypt The Cross, plain or jewelled, and sometimes of the looped form borrowed from an Egyptian hieroglyph, first appears in the 3rd or 4th century, to be followed by Alpha and Omega, the dove and other emblems A little later, subjects from the Gospels and the Old Testament are found By this time two significant changes have come about Embroidery tends to replace woven ornament and silk becomes a common material

Persia and Syria.—Persia, the land whence came the first silk threads used in the West, now claims attention From the beginning Persia held the monopoly of the import trade in raw silk from China, and this it long kept, in spite of efforts made to evade it by exploring a northern route round the upper shores of the Caspian and a southern one by sea The earliest known Persian textiles belong to the time of the Sassanian kings, who ruled from A D 211 until the Mohammedan conquest towards the middle of the 7th century No silk fabrics of that time are now known to exist in Persia, but their nature may be learned from contemporary rock-cut reliefs, representing the royal exploits and amusements Textile-patterns shown in these are so characteristic, and so faithfully rendered, that with their aid a number of silk stuffs from various sources may be identified Chief among them is a green silk with a dragon of peculiar design evidently derived from the art of ancient Babylonia and Assyria It is identical with that on the robe of the Sassanian king Chosroes II in rock-cut reliefs at Tak-i-Bostan near Kirmanshah The same relief identifies as Sassanian a silk stuff with cocks in roundels, found in the Cappella Sancta Sanctorum in Rome in 1905 Other stuffs of this group are in the cathedral treasury at Sens in France, in the treasuries of Sion and Saint Maurice d'Agaune in Switzerland, and at Aachen in Germany Fragments have also been found in the buried sites of the Gobi desert region in Central Asia

A few other silk stuffs of the period are more obviously imbued with the spirit of Greece and Rome, and these may have been woven in Syria. The chief among them, with a pattern of Nereids riding on sea-monsters, is in the church of Notre-Dame de Valère at Sion in Switzerland Another remarkable example, with a leopard attacking a bowman, is in the treasury of Sens cathedral.

One of the finest of all existing early silk stuffs has a pattern of large circles with representations of the Annunciation and the Nativity (Plate II., fig. 3). It was found in the Cappella Sancta Sanctorum in Rome, and it is now in the Vatican museum. Another fragmentary silk of great interest, at Sens, represents the story of the patriarch Joseph. A few silk stuffs with Christian subjects have been found in Egypt, as well as a far larger number of Persian origin. Among the latter, those with bowmen on horseback shooting arrows behind them are typically Persian.

Sassanian influence persisted long after Persia had been overrun by the Mohammedans. It is very plainly seen in two remarkable silk stuffs which were carried to Germany in early mediaeval times. One is in the church of St. Ursula at Cologne It shows a Sassanian king riding on a griffin and slaying a mythical beast In the other, found in the neighbourhood of Trèves, a Sassanian king holds aloft a lion cub which he has snatched from a lioness. This exploit is told of Bahram Gor. The silk is now in the Berlin museum. The most remarkable Persian silk weaving of these times was found in the year 1920 in the church at Saint Josse-sur-Mer near Boulogne, whence it was transferred to the Louvre (Plate I., fig. 2). It has a large design of elephants, and a string of Bactrian camels for a border. An inscription in Arabic characters indicates the province of Khurâsân as the place of origin, and approximately the year A D. 960 as the date

Byzantines.—Very little silk weaving (*q v.*) was done in Europe before the secret of silk-cultivation was learned. Both Aristotle the Greek in the 4th century B.C, and Pliny the Roman in the 1st century A.D., give an account of the silkworm Aristotle seems to have gained some knowledge from the soldiers of Alexander the Great, and apparently he had heard of wild silk, but neither he nor Pliny knew much about the matter. Heliogabalus (A.D. 218–222) is said to have been the first emperor to wear a robe entirely of silk, and Aurelian (270–275) declined to allow his wife a silk mantle because of its high cost.

Silk-weaving was already carried on at Constantinople in the 4th century, but the industry cannot have been of much importance until the eggs of the silkworm were surreptitiously brought over by Persian monks from China in the reign of Justinian (527–565), as Procopius relates, and the long-guarded secret of the Chinese was exposed.

Constantinople was situated at the junction of two continents, and as it was the *entrepôt* of the trade between Europe and Asia, the influence of the East was paramount there. The emperors maintained their own weaving school in the capital, and some of the stuffs were intended solely for the use of the emperor and the court. We learn a little about this from Liutprand, bishop of Cremona, who went to Constantinople in the year 968. He bought some silk stuffs there for Otto I., but five purple stuffs were confiscated by the officers of the customs, on the plea that they were only to be worn by the Byzantines. The bishop protests that he had seen as good stuffs in the West, brought by the merchants of Venice and Amalfi, and he asks why he, a bishop and an emperor's ambassador, should be treated as no better than a Venetian merchant.

Three very remarkable Byzantine silk weavings are of such historical importance that a brief description of them must be given. The first was found in the shrine of St. Anne in the abbey church of Siegburg. Two lions in profile advance towards one another. Between them is a Greek inscription to the following effect: "Under Romanus and Christophorus, our most Christian rulers." These two emperors ruled jointly at Constantinople from 921 to 931. The two lions with the intervening inscription cover a length of about five feet. Perhaps it was a stuff of this kind which formed the subject of Liutprand's complaint. The second silk is similar, but the inscription refers to Constantine and Basil, whose joint rule lasted from 976 to 1025. It was found in a church in the Lower Rhine district, and pieces are now in the Berlin, Düsseldorf and Crefeld museums.

The third fabric was placed over the body of the Emperor Charlemagne in his shrine at Aachen. It has a pattern of large circles, each enclosing an elephant, strongly conventionalized and bearing rich jewelled trappings, Along the bottom there is an abbreviated inscription giving the names of certain officials. This stuff is later than the time of Charlemagne; it probably belongs to the end of the 10th century. For boldness of design and general splendour these three silk fabrics, woven on the imperial looms of Constantinople in the 10th century, are among the chief mediaeval stuffs we now possess. Weavings of this character probably came to an end with the sack of Constantinople by the Latins in 1204.

Sicily and Spain.—It is remarkable that Mohammedan textile art flourished nowhere as it did on European soil, and partly under rulers who were the enemies of Islam. The first Arabic incursions into Sicily took place in the 7th century, and during the course of the 9th century the island fell definitely under Mohammedan rule. Silk and gold stuffs were woven in Sicily in the 10th century, but they cannot be distinguished from those woven in other Mohammedan lands. In the year 1060 the Normans arrived in the island, and the Mohammedans were finally subjugated Weaving went on very much as before, though with greater magnificence and luxury, if we may judge from the two imperial robes produced at Palermo in the years 1134 and 1181 (described later) The lining of the great mantle is woven in silk and gold thread with figures representing the Temptation in the Garden of Eden, trees, birds, interlacing bands and Arabic lettering. A similar stuff, with horsemen, animals, birds and serpents is in the tomb of Roger, Norman ruler of Sicily (1072–1111), at Palermo. A brocade in pink silk, with a small pattern of gazelles, birds and trees in gold, formed part of the robe in which the emperor Henry VI. (d. 1197) was buried at Palermo; there is a fragment of this stuff in the British Museum

The other great centre of Mohammedan weaving in Europe is Spain There the Arabs landed in the year 711, and within seven years they were masters of the whole peninsula except the northwest By the 9th century the weaving of silk fabrics was established in Andalusia. A remarkable woven fabric, known as the "veil of Hishâm," bears the name of Hishâm II, khalif of Córdoba from 996 to 1021. The material is a thin gauze, and the inscription borders a stripe of ornament woven in silk and gold thread, similar to the contemporary weavings of Egypt. In the 12th and 13th centuries some remarkable silk and gold fabrics were woven, with pairs of animals or birds, often in circles. Before the end of the 14th century the peculiar type of arabesque ornament, relieved by bold lettering, associated particularly with the decoration of the Alhambra at Granada, began to be seen in silk fabrics The colours are bright—red, yellow and blue predominating. Upon the final subjugation of the Moors at the end of the 15th century, and the re-entry of the whole peninsula into Christendom, the skill of the Mohammedan weavers was still employed for producing stuffs "oeuvrés à la moresque," but the influence of Italian design grew as the 16th century advanced. With the rise of the textile industry at Lyons French influence began to be felt.

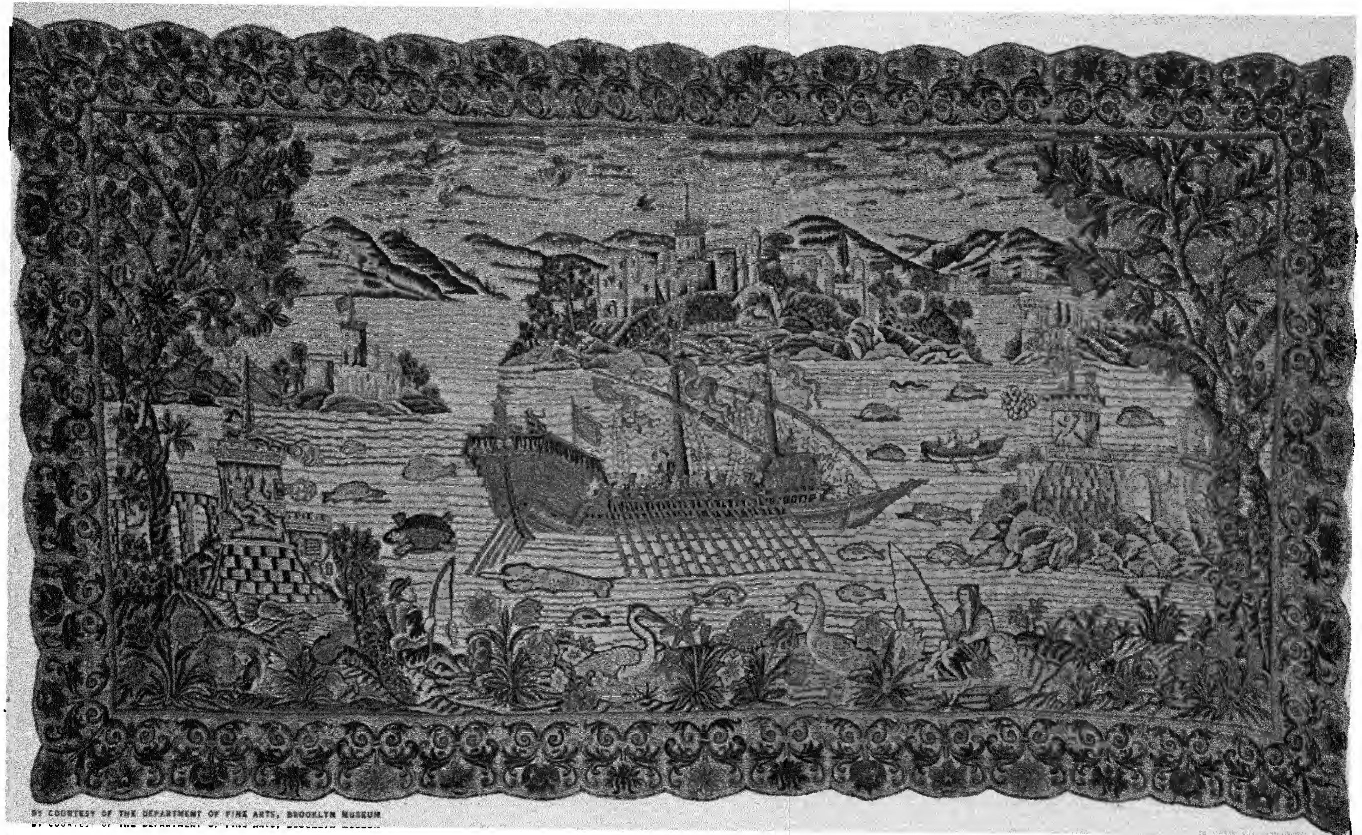
Italy and France.—The great textile industry of Italy, though much influenced by oriental art, followed a more independent course than that of Spain. The soil and climate were favourable to the growth of the silkworm, and Italy became the chief centre of that industry in Europe. Looms were set up for weaving the thread into fabrics. As early as the 12th and 13th centuries silk weaving industries were found in the great cities of the north, such as Florence, Venice or Genoa. In the south they grew up as the political upheavals of Sicily led to the migration of craftsmen to more peaceful industrial centres. In the 14th century Lucca became famous throughout Europe for its woven stuffs.

Silk weaving was also carried on at Venice, Genoa, Vicenza, Florence, Bologna, Milan, Turin, Siena, Naples, Catanzaro, etc. In the second half of the 15th century Florence had a large number of factories, sending stuffs to Rome, Naples, Genoa, Catalonia, Seville, Lyons, Avignon, Antwerp, Turkey and elsewhere. In the 18th century stuffs were still sent to Holland, Germany, Turkey,

BY COURTESY OF YAMANAKA AND COMPANY

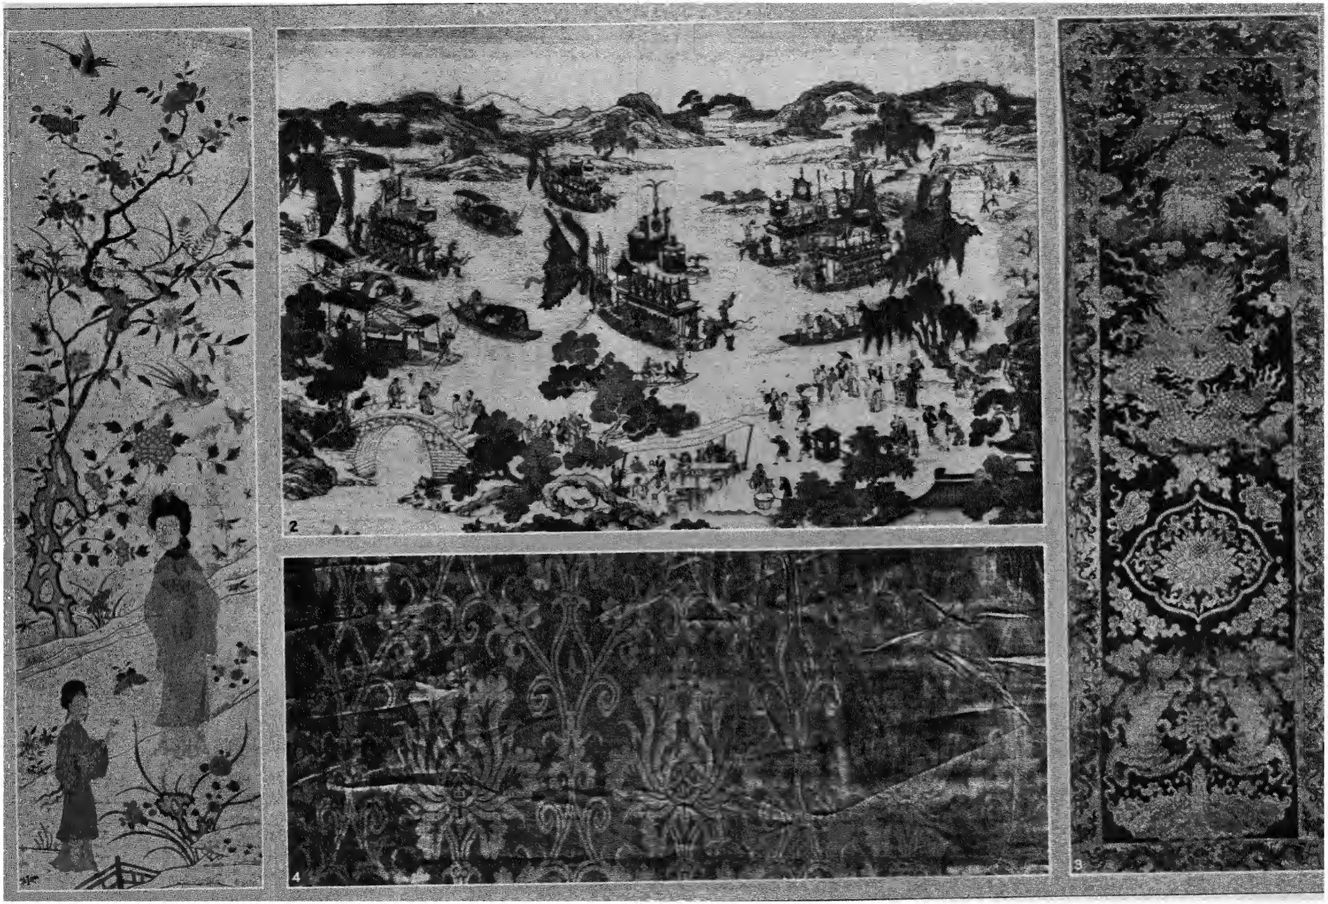
WOVEN BROCADE HANGING

A wall hanging of woven brocade of the Ming Dynasty, 15th century. This hanging, woven entirely in one piece, was originally made for the Winter Palace in the Province of Jehol, Mongolia



PORTUGUESE NEEDLEPOINT

Tapestry of early 18th century Portuguese needlepoint. The design, which is in the *gros point* stitch worked out with polychrome silk threads on a ground cloth of canvas, commemorates the return of Ferdinand Pinto, a Portuguese adventurer and traveller, from the East. The choice of an historical event for the subject of the design, as well as the brilliant colour and the scalloped border, is characteristic of Portuguese work of this period. The tapestry, owned by Quill Jones, is now in the Brooklyn Museum, New York



CHINESE TEXTILES

1. Early 18th century wall-hanging of white satin embroidered with colored silk
2. One of a series of four panels representing the Dragon Boat Festival in honor of Chu Yuan, statesman and poet, who was drowned in Milo River, 295 B.C. This panel is of embroidered silk, middle 18th century
3. Eighteenth century Chinese red velvet chair cover. The embroidery is done with gold threads on red satin background
4. Ming dynasty (1368–1644) woven damask. The character found in each flower, as well as the design and texture of the material, indicates the work is of Chinese origin

TEXTILES AND EMBROIDERIES

PHOTOGRAPHS, (1) HERBERT G. PONTING F.R.P.S., (2) BURTON HOLMES FROM EWING GALLOWAY, (3) PUBLISHERS PHOTO SERVICE

EMBROIDERERS AT WORK

1. Skilled Japanese embroiderers at work in Kyoto, Japan. They succeed in producing a product that will defy many destructive elements
2. Swiss embroiderers working in front of a shop in Lucerne, Switzerland
3. Hungarian woman displaying a sample of the beautiful embroidery characteristic of that country. Heavy thread is used to create many of the effects produced

Barbary and South America. The Venetians, too, carried their operations far afield. It was claimed for them that they studied to suit the colours and quality of their fabrics to the markets for which they were destined, both in Italy, and "all over the world."

The foundation of the silk-weaving industry in France in the 16th century, and its subsequent enormous development, challenged the Italian monopoly. Italian weavers were attracted to France. At Tours there were numbers of Genoese, and in the early days of the industry at Lyons there were many Genoese and Florentines Weaving was also carried on in other French towns, but during the 17th century the highly organized industry at Lyons gradually grew until it outstripped the Italians and reached that eminence which it has since maintained throughout Europe

Great Britain.—For many centuries Great Britain was provided with the silks it needed from abroad Henry VII., when he desired to give some vestments to Westminster Abbey, had specially woven for him at Florence at great cost some magnificent fabrics of red velvet and cloth of gold with a pattern of roses and portcullises. One of these vestments is still preserved at Stoneyhurst college (Plate I, fig 4).

In the 16th century much silk was worn in England, but very little was woven, and Italy was still the chief source of supply In the following century, in a speech from the throne James I urged mulberry-planting for rearing the silkworm It was tried, and foreign weavers were brought in. Silk culture did not prosper, on account of the late spring, but weaving went on, and there were already large numbers employed when the revocation of the edict of Nantes brought in many thousands more refugees connected with the silk industry Voltaire, who spent some years in England a generation later, speaks of an entire suburb of London (*i e*, Spitalfields) peopled with French manufacturers of silk. Others settled in Soho, Long Acre or Seven Dials. Weaving industries also grew up at Canterbury, Norwich, Sandwich and other provincial towns It was claimed that the Canterbury stuffs equalled any foreign silk.

During the 18th century the brocades of Spitalfields followed pretty closely the work of Lyons, and it is not always possible to distinguish between the two. Although gold and silver thread were made in the parish of St. Giles, Cripplegate, metal threads were not so freely used by the Spitalfields weavers, and patterns tended to be a little simpler The industry has now left Spitalfields, and subsequent work in East Anglia, though shrunken in output, still maintains the same high standard of craftsmanship and materials.

Persia and Turkey.—When Persia emerged again from alien rule early in the 16th century under the Safidian dynasty, a new era for the arts was inaugurated. The Shahs had their own establishments of craftsmen with a director-general, and overseers for the separate crafts. Some followed the movements of the court, others were settled on the royal estates and in convenient centres. The best materials were supplied, and there was no stint of labour or expense. Under such conditions, some of the most remarkable stuffs ever woven were done in Persia The most sumptuous velvets, with human figures, birds and trees, often on a gold ground, were made (Col Plate, fig 2). Brocades represented historical scenes, figures, landscapes, animals, birds and flowers The floral patterns of Persian stuffs are unsurpassed anywhere in the world. During the 18th century and subsequently, foreign intercourse has led in some degree to the adaptation of European patterns.

What is geographically classified as "Turkish" art is not the indigenous art of the once nomad Turkish tribes who ultimately overran Asia Minor and south-eastern Europe and there established a heterogeneous empire. It is the art of the conquered races under Turkish rule. Nevertheless there does gradually emerge, in those lands a unified art, largely under Persian influence, but not altogether unaffected by the relations of the Ottoman Porte with Italy (particularly with Venice) in the 16th and subsequent centuries. A brocade in the Lyons Museum, with a pattern of pairs of lions within roundels, in gold thread on a red silk ground, has an Arabic inscription giving the name of Kai Kubâd, the Seljuk Turk, sultan of Iconium (Konieh) in Asia Minor in the early years of the 14th century. This important stuff shows some affinities with Byzantine art. In the 16th century velvet brocades recalling the contemporary lobed or "Gothic" patterns of Italy but with a strong oriental bias, were woven in Turkey both for home use and for export

Embroidery.—Like all other crafts, embroidery had its origin in the daily needs of humanity. The problem how to join two edges of a fabric together must have arisen very early, and even a seam, as so many oriental embroideries show, may be treated decoratively Once the needle was invented, whether a sharp fish-bone, a thorn, a pointed stick, or a metal wire, the natural instinct to pass the limits of mere utility and to indulge in decoration would make itself felt. A good deal of what has been said above about woven patterns is applicable to embroideries. A few embroideries, mostly in wool, though gold thread occurs as well, were among the stuffs found in Greek graves in the Crimea (*see* above). One in particular, of the 4th century B.C., shows an Amazon on horseback. In later Roman times embroidery was practised very much in the same way as it is today, as examples from Egypt show

Perhaps the most sumptuous of all mediaeval embroideries is the imperial mantle at Vienna It is of red silk, with a lion springing upon a camel, worked in gold thread and silk and enriched with pearls and gems An Arabic inscription round the edge records that it was made at Palermo in Sicily in the year 1134. The design probably has reference to the capture of the island from the Arabs by the Normans, which had then recently taken place The imperial alb, also at Vienna, has a border of griffins in gold embroidery. An inscription in Latin and Arabic records that it was made at Palermo in 1181.

England was renowned for its embroidery ("opus anglicanum") in mediaeval times, and a number of remarkable English vestments are still preserved in England and on the Continent. Embroideries of Elizabethan times show much beauty in design (*see* DRESS) A strong oriental bias, due to trade with the East, is found in the 17th century. The great flowering trees worked in wools are copied from Indian designs. The 18th century maintained the standard of earlier times, and much has been done of late years to encourage this beautiful craft.

French mediaeval embroidery has much of the sweetness and grace that we should expect to find Later work has reflected the various influences which have moulded French art. Early Spanish work has Mohammedan characteristics. In later times, embroidery in the peninsula runs parallel with the Italian, but there is a tendency towards greater elaboration and brighter colours. The influence of Italy became widespread through its pattern-books for embroidery and lace-work, copies of which were carried to other countries and sometimes reproduced. In the Netherlands the work of the great schools of painting which arose in the 15th century is reflected in embroidery. The embroidery of Germany and Scandinavia is largely domestic in character. In the islands of the Aegean, peasant embroidery has reached a stage of development hardly matched on the continent of Europe. The embroideries are mostly in silk upon linen, for dress and domestic use Different islands have their own distinctive patterns.

In Turkey and Persia embroideries have followed a parallel course to woven fabrics, and similar motives are used A great deal of embroidery in silk and metal threads upon linen scarves and towels was done in Turkey during the 19th century. Much white-work has been done in Persia.

INDIA

Indian textiles have been famous from remote ages. Cotton was known to the Babylonians as *sindhu*, to the Greeks as *sindon*, and the natural inference as to its origin has been lately confirmed by the discovery at Mohenjo Daro, in the Sindh valley, of true cotton (*Gossypium*) fabric dating from the 3rd millennium B C. It was not until the 13th century that the plant was introduced into

southern Europe. Imitations of Indian cotton were first made in Manchester in the 17th century, but the imported material held its ground Numerous English names of cotton fabrics are of Indian origin. calico from Calicut, cramoisy from the *kermes* insect, chintz from Hindī *chint, cita,* meaning spotted or variegated, bandana from *bandhnā,* the process of tie-dyeing, shawl from Hindī *śālā.* From the most ancient times plain and decorated cottons of all sorts have been used in untailored lengths to form the principal elements of wearing apparel—*dhoti* or lower piece, *dupaṭṭā* or scarf, and *pagrī* or turban, and the *sārī* (draped robe) or *ghagrā* (skirt) worn by women Perhaps the most famous weaves are those of Dacca, including both decorated fabrics of some strength, and the filmy undyed muslins (*malmal*) known by such poetical names as "running water," "woven air," and "evening dew"; the last named may be woven of yarn so fine as to require 250 m of it to weigh a pound, and as much as Rs. 500 may be paid for a piece of plain muslin 10 yd in length by 1 in width. In many early Indian sculptures it is indicated that muslin garments are worn, but they are so thin and transparent, except where the folds or edges of the material appear, that the figures seem to be nude.

Silks are mentioned in the Indian epics, but these may have been imported from China Three varieties of silkworm are native in India (*tasar, muga,* and *eri*), but it is not certain that the true mulberry silkworm was ever cultivated there before its introduction by the East India company in the 17th century The main types manufactured are the plain, figured or shot material, satins chiné and brocade Typical of present day production are the brocaded silk gauzes of Benares

Woollen shawls and blankets are commonly met with in the Punjāb; but the most famous woollen textiles of India are the shawls (*Śālā*) and cloaks (*chogā*) of Kashmir Nothing of high quality has been produced for many years, but fine old examples are common both in Europe and America, and in the collections of Indian princes Kashmir shawls should be carefully distinguished from the machine-made Scotch imitations known as Paisley shawls, from the place of manufacture.

The Kashmir work is of two kinds, woven (*tili* or *kanikar*) and embroidered (*amlikar*); the wool used is the under fleece (*pashm*) of a goat The work is produced by a collaboration of at least four craftsmen, a designer, colour-designer, the man who plots the weave, and the actual weaver Whether woven or embroidered, a Kashmir shawl is almost always made of many small pieces, which are separately prepared and joined together; the joining is so skilfully done as to be almost imperceptible. The peculiar "Kashmir shawl pattern," "wind-blown cypress," "cone," or "flame" pattern, as it has been variously called, is known to the weavers as *būtā,* a term used throughout India to denote any floral motif in design The Rampur *chādar,* a square shawl, cream coloured, without ornament or with embroidery of the same colour, has generally a silk weft, and, still made in a good quality, is sometimes known as a ring-shawl, from the fact that the fineness of the texture makes it possible to draw the whole of such a shawl through a finger-ring. The best detailed accounts of the making of Kashmir shawls are in Moorecroft's *Travels,* and Watt's record of the Delhi exhibition of 1902–03 (*See* Bibliography)

Dyeing.—Coloured garments of wool and silk are often referred to in the epic period and in literature Some elaborate textile designs appear in the early reliefs, others in Gupta sculpture and the paintings of Ajantā, later on also in the paintings of the Gujarātī and Rājput and Mughal schools A *haṁsa lakṣaṇa* (goose pattern) is often referred to in the literature, appears in the paintings alluded to, and is still made in muslin brocade at Aurangābād. The most important Indian dyes are indigo (*nīl*), madder (Mañjiṣthā, "Manjeet") and *chaya* root Synthetic dyes have now come into general use

Indian dyes are applied in two ways, either to the warp and woof threads to be afterwards woven into self-coloured, patterned, or shot fabrics; or repeatedly to a finished textile, usually cotton, whenever it is washed, or a change of colour is desired. The most remarkable work of the latter kind may be studied in the elaborate zigzag designs of the turbans of Kota and Alwar; a fabric may even be double-dyed so as to appear of different colours back and front. For the various methods of applying a dye or dyes locally to produce a coloured design on a finished fabric, *see* below.

Block Printing and Painting.—These processes range in complication from simple printing in black on white from wood blocks, through combinations of block printing in many colours combined with dye painting, to work entirely dye-painted by hand, and with or without the use of a resist The technique is almost exclusively applied to cotton, and material for garments, bed covers, and hangings of all kinds is produced

IMPRESSIONS OF 19TH CENTURY WOOD BLOCKS USED FOR STAMPING EMBROIDERY DESIGN (LEFT) AND FOR COLOUR PRINTING (RIGHT)

To give a very simple example of the process, a resist paste of lime and gum, or oil and beeswax, may be printed from wood blocks, the cloth is then dipped, and when the resist paste is subsequently removed, a white pattern on a coloured ground remains The art has reached its highest developments in Rajputana and Masulipatam The latter town, in the Madras presidency, has long manufactured printed and painted cottons both for local use and also in special designs for export to Persia on the one hand, and Siam on the other At Masulipatam the process is largely one of hand painting (*qalmdar*) with a brush or pencil (*qalm*) made of steel wires, with this brush a design is drawn in hot beeswax, which penetrates the material, and after dyeing, the wax is removed by boiling Although a different tool is used, this is essentially the process known in Java as *batik* (*q v*). In the case of a design of many colours, the process must be repeated for each colour The most noteworthy productions of Masulipatam and Kalahastri in the south are the well-known *palampores.* In design these are of two types; those of the *mihrāb* type, suitable for hangings, but essentially of the Mohammedan prayer mat type, and having the main element of the design consisting of a beautifully designed tree of life with birds and animals; and those representing mythological subjects, mainly intended for canopies to be used in Hindu temples.

Tinsel Printing and Painting.—In the "wax cloth" technique of Peshāwar a preparation (*roghan*) of oil just stiff enough to be drawn out into threads by the iron style which is used in making the design, is applied to the ground, then gold, silver powder or gold leaf is applied, and this naturally adheres only to the *roghan* As the *roghan* is often mixed with powdered lime to give it body, the resulting design stands a little above the general surface, and we have practically a form of *gesso.*

The most exquisite and delicate tinsel printing is done in Rajputana, largely on fine muslins intended for *pagris* or turbans Here glue, gum, or lac is first printed from a wood block, and then gold leaf pressed on to the surface Very often the gold is employed on a coloured design of floral motifs previously prepared. The technique is practised in other parts of India, but perhaps the most magnificent examples are the gold printed batiks of the island of Bali, known as *kain prada.*

The special and highly developed technique of tie-dyeing (*bandhnā, cunari*) is practised chiefly in Rajputana, Central India, Gujarāt, and in the island of Bali In this technique, a design is worked out, typically in spots, but also in squares or zigzags, by an elaborate process of tying up small portions of the cotton or silk fabric so tightly that the tied parts do not take up the

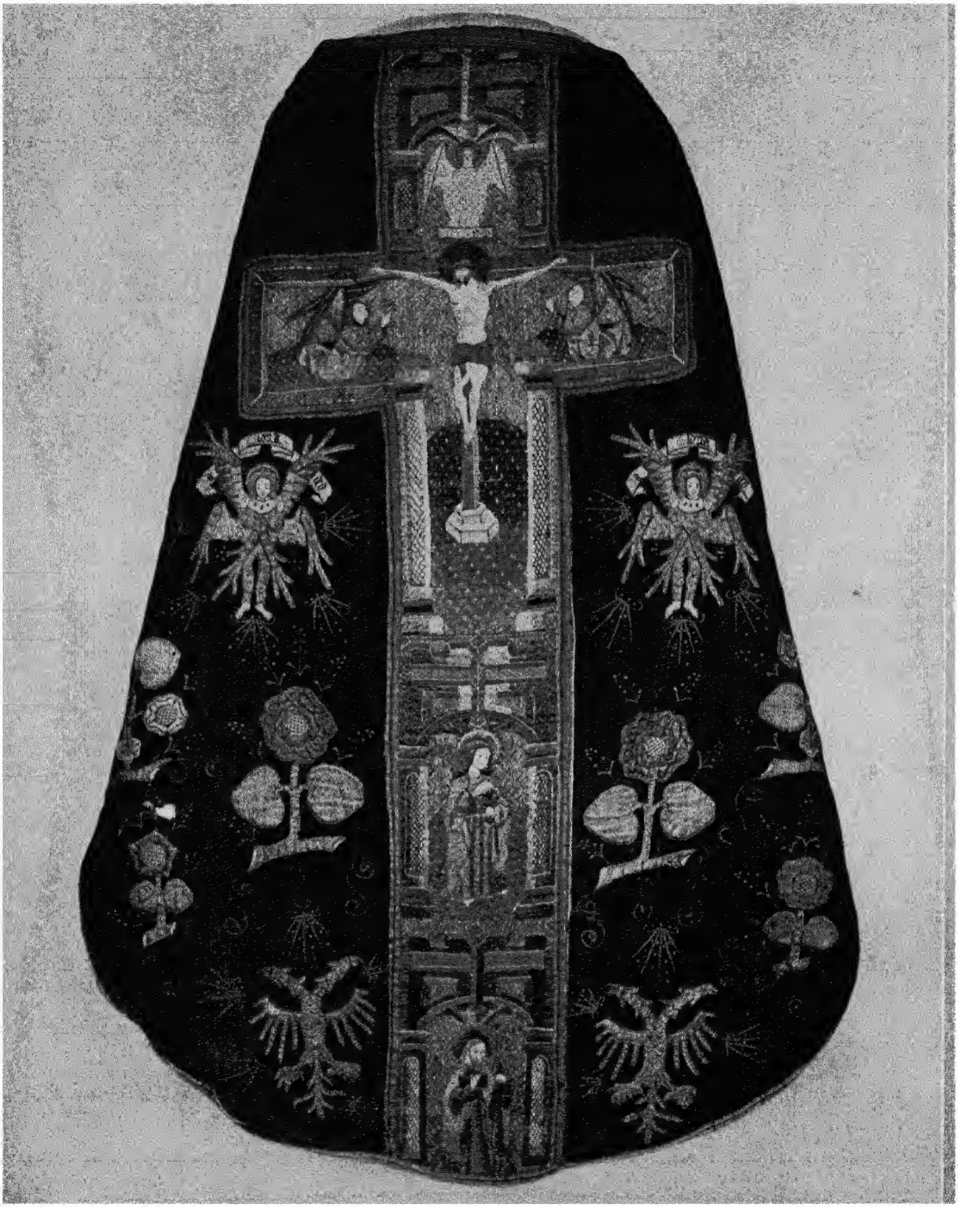
EUROPEAN AND NEAR EASTERN TEXTILES

1. Fragment of silk, about A.D. 960, from Khurasan, Persia, with representations of elephants and, in the border, camels. This piece, as illustrated, found in 1920 in the church of St. Josse-sur-Mer near Boulogne, is now in the Louvre
2. Persian embroidery with characteristic designs of birds and floral patterns
3. Cope of red velvet and cloth of gold, with a pattern of roses and portcullises. Woven at Florence as a vestment for Westminster Abbey during the reign of Henry VII. (1457–1509), it is now at Stonyhurst College, England
4. Detail of the border of an 18th-century Egyptian linen hanging, with floral embroidery in wool

TEXTILES AND EMBROIDERIES



EMBROIDERED CHASUBLE

Early 16th century chasuble of dark blue velvet, orphreys and ornaments embroidered on linen with silver gilt threads and coloured silks, 4'2" x 3'5". A chasuble is worn as the outer vestment of the celebrant at the Eucharist

colour when the fabric is dipped. The process must be repeated for every colour element in the design.

In the elaborate "Chiné" weaves (*paṭolas* and *ikats*) the characteristic feature is that the warp or woof threads, and often both, are individually and locally coloured by a tie-dyeing process before the warp is laid; the distribution of the colour on each thread is carefully calculated, so that the pattern will appear when the cloth is woven, without further manipulation. The term Chiné (Italian *alla Chinese*) is French, the fabrics having reached Europe from the East, but the technique is not Chinese. From the sporadic distribution of the method it may be inferred that it is a very ancient one, and perhaps of Indian origin. It extends to Turkey, and from Persia and Turkestan (Bokhara velvets and *dārāī* silks) through India (Gujarāt and the Dekkhan, but not in Ceylon) to the Malay peninsula (Tringannu), Sumatra, Java, Bali and Cambodia, and in a very simple form (*kasuri*) to Japan. Best known are the *paṭolas* (silk *sārīs* worn at weddings) of Gujarāt (Cambay and Baroda), under this name, the material has also been extensively exported to Java and Bali, where it is much prized. Very fine and elaborate examples in which both warp and woof threads are dyed reproduce animal and floral motifs. The same technique is employed in the preparation of striped *khañjarī mashrus*, mixed silk and cotton fabrics used by Muslim women and made in the Punjāb, Benares and at Ayyampet in the Tanjore district, mainly for the Haidarābād market. The gorgeous *ikats* of Sumatra are generally interwoven with gold thread. The double *ikats* of Tenganan in Bali are of cotton, and are used as coverings for temple offerings. Fine and large examples of cotton *ikats* are made in many other islands of the archipelago, the garments and shrouds from Sumba being the best. In Cambodia very beautiful silk *ikats*, known as *sampot hol*, are still made by traditional methods under the supervision of the Direction des Arts Cambodgiens at Phnom Pen.

Brocades.—These are textiles of silk in which the pattern is distinct from and supplementary to the weft, and thrown on its surface, small needle-like spools being thrust between the warp threads wherever the design requires; the term is generally used in connection with silk fabrics, but the method of weaving flowered muslins (*jamdānī*), the decorated cottons (*ctirili*) of Ceylon, and the *kanikar* type of Kashmir shawls is essentially the same. Silk brocades may be of pure silk (*amru*), or silk and cotton (*himru*) or interwoven with gold threat (*kimkhwāb*); these types pass into each other by gradual transitions, and the *kimkhwāb* ranges from types in which metal threads are very sparingly employed to pure cloth of gold or silver. Of pure silk brocades none is more beautiful than those of Surāt, which have floral sprays all over them and borders of conventional trees; the most exquisite of the *kimkhwābs* are those of Benares (already famous for its textiles before the Gupta period), Ahmadābād, and also Aurangābād.

The making of gold thread (*kalābatun*) for use in weaving and embroidery is still a flourishing industry, as much as 300,000 m per annum being produced in Delhi alone. This is a highly specialized craft. Silver gilt wire is first drawn through fine holes in an iron plate until no thicker than a hair, then beaten flat on an anvil, then twisted round a silk thread foundation.

Embroidery.—Only a very few of the most important types of Indian embroidery can be discussed. Embroidered garments and needles are mentioned already in Vedic texts, and although the use of untailored draped material is characteristic of Hindu culture, tailored garments have been in use from a remote period.

The *phūlkārīs* worn by Jāt women of the Punjāb and Rajputana are well known in Europe, they are used as hangings. These are executed in a darning stitch, done from the back, in white or yellow silk on coarse red cotton, in diapers or floral designs covering the whole ground; in good examples the stitches are very close and short, and the regularity of the design is secured by careful counting. Another type is carried out in cross stitch, with effects like those of European samplers.

Exquisite work in chain stitch is characteristic of the Punjāb, Rajputana, and Kach. In one type, known as *shīshadār*, and used in embroideries for many purposes, small pieces of mirror glass, manufactured at Karnak, are introduced into the design, and bound down by stitching round them. In the Punjāb, the embroidered floor coverings are especially admirable, in Jaipur, hangings and shield cushions; in Kāthiāwār (Kach), the brilliantly designed and coloured women's skirts and children's caps with the long flap hanging down behind. Perhaps the finest of all chain stitch embroidery is met with on the *kamarbands* of Murshidābād or Azamganj in Bengal. Excellent examples in a bolder style are to be found in the betel bags of Ceylon, where the elaborate binding stitches are also of great interest.

The beautiful *kasīda* embroidery of Dacca in Bengal is done in gold coloured *muga* silk in darn and satin stitch on muslins. Finer and more elaborate is the *chikān* work of Lucknow, done in white or cream cotton on muslin, often in combination with drawn thread work. Here the design is usually printed from a wood block in a colour that can be easily washed out, and the blocks used for this purpose should not be confused with those used for cotton printing with permanent dyes. Some of the work is characterized by the use of raised knots. The net embroidery, often spoken of as drawn thread, is really produced entirely by the needle, the strands of the fabric being pushed to one side by a kind of buttonholing, without the drawing of any threads, which is regarded as a slovenly imitation of the real process.

Heavy embroidery in raised gold thread is mainly applied to elephant trappings, palankeen canopies, and the like; but much is now made at Delhi in forms adapted to European requirements. Appliqué work is found in Ceylon and Burma, quilting all over northern India, goffering in various places. (*See* also LACE; FAN; WEAVING.)

THE FAR EAST

Woven Fabrics of China.—The origin of silk-weaving (*see* WEAVING) in China is lost in the region of myth and legend, and nothing remains to show what the earliest stuffs were like. The oldest Chinese patterned stuffs known to exist were unearthed by Sir Aurel Stein in the Lop desert, Chinese Turkestan, in 1914. The site lay on the route opened out by the Chinese for the silk trade with western Asia in the 2nd century B.C., and replaced by an easier route in the 4th century A.D. The stuffs are attributed to the 1st century B.C., during the Han dynasty, and they are undoubtedly influenced by earlier traditions. The patterns of dragons, griffins, animals, birds, scrolls and diapers are archaic in form, though at the same time they have a remarkable resemblance to later work. The next Chinese dynasty especially associated with the output of artistic wares is the T'ang (A.D. 618–906). Considerable numbers of textiles attributed to this period have been preserved. The Chinese were then in contact with Persia both by land and sea, and this western intercourse is reflected in the art of the time. It is conspicuously seen in a silk banner said to have been used by the Japanese Prince Shotoku (A.D. 572–623), and now removed from Nara (the old imperial capital) to the Tokyo museum. The design is a typical Sassanian

hunting-scene, with the king on horseback attacking a lion; the manner of representation is, however, Chinese and Chinese characters are introduced. Many other silk weavings of this epoch are preserved in the royal treasure-house at Nara in Japan.

A characteristic type of Chinese weaving, done by the tapestry method in fine silks and gold thread, and known as k'o-ssu, is first met with under the T'ang dynasty. The specimens which have been found in the Gobi desert region differ remarkably little from those of modern times The same very fine silk warp is used, and the weft of bright coloured silk enhanced by the use of gold thread. On the other hand there can be no reasonable doubt that these examples woven more than a thousand years ago were the heirs of a far greater antiquity—perhaps assignable in its origin to the dim period when Chinese handicrafts first assumed a civilized form. The patterns are less archaic than those of the "Han" silks already mentioned, but they are similar in their scope —including dragons, symbolic "lions," phoenixes, and various animals, birds and flowers.

Under the Yuan dynasty, founded by a Mongolian conqueror about 1280, Marco Polo (besides other travellers from Europe) found his way across the Asiatic continent to China He speaks of the silk brocades woven in many parts of that country Numbers of Chinese silk and gold fabrics were brought to the West at that time and under the Ming dynasty which followed in the 14th century. Some are at Regensburg and Danzig and in other church treasuries of Europe Occasionally Arabic inscriptions are inwoven into these stuffs showing that they were intended for the use of a Mohammedan ruler of western Asia

With the arrival of the Portuguese at Canton in 1517 a new era begins for Chinese textiles. "Chinoiserie" soon came into vogue in Europe, and the trading ships of Portugal, Spain, England, France, Holland and other countries brought home vast quantities of Chinese textiles often made specially for export During this time the weaving of fine silk fabrics, uninfluenced in design by Western associations, went on as before. Dragons, phoenixes, clouds, waves and symbolical ornaments were reproduced on official garments, temple hangings and other stuffs. In China a landscape or a figure subject becomes a "pattern" almost as naturally as any other kind of ornamentation. Landscapes including rocks, rivers, boats, buildings, trees and figures were rendered by the tapestry-weaving process already described. A panel belonging to a series representing a popular commemorative festival held annually by the Chinese, is here reproduced (*see* Plate I.)

Woven Fabrics of Japan.—Textile art in Japan owes a great deal to the Chinese. The ancient royal treasure at Nara, already mentioned, contains some of the most remarkable early Chinese stuffs in existence. The inference that Japan was then very largely dependent upon the more ancient civilization of her neighbours for the richer sort of textiles is confirmed on more general grounds. In the early centuries of the Christian era large numbers of Chinese weavers settled in Japan. They usually worked under Japanese control, and they became distributed throughout the country.

In the year 1584 a Japanese embassy arrived in Europe, visiting Pope Gregory XIII. in Rome, and King Philip II in Spain. They brought with them silk weavings as presents, receiving in return velvets and brocades From this time onwards European influence may be discerned here and there in the textiles of Japan. But before the 17th century was well advanced, Japan closed her doors entirely to the foreigner, until in 1858 the country was reopened to European and American trade by Com Perry, U.S. Navy.

Japanese textile-design displays an acute perception of natural forms, seizing the salient features and transforming them with a light touch to the fabric. Ducks are shown floating on the rippling water, irises growing in the stream, fowls with their chicks (*see* Plate II), cranes on the wing; and with these are landscape effects —lakes and streams, clouds, pine trees, castles and bridges. Symbolic ornaments and small diaper patterns are also common. Different methods of ornamentation are frequently combined in one fabric. A silk stuff may have a woven pattern helped out by printing and completed with a few deft touches of embroidery.

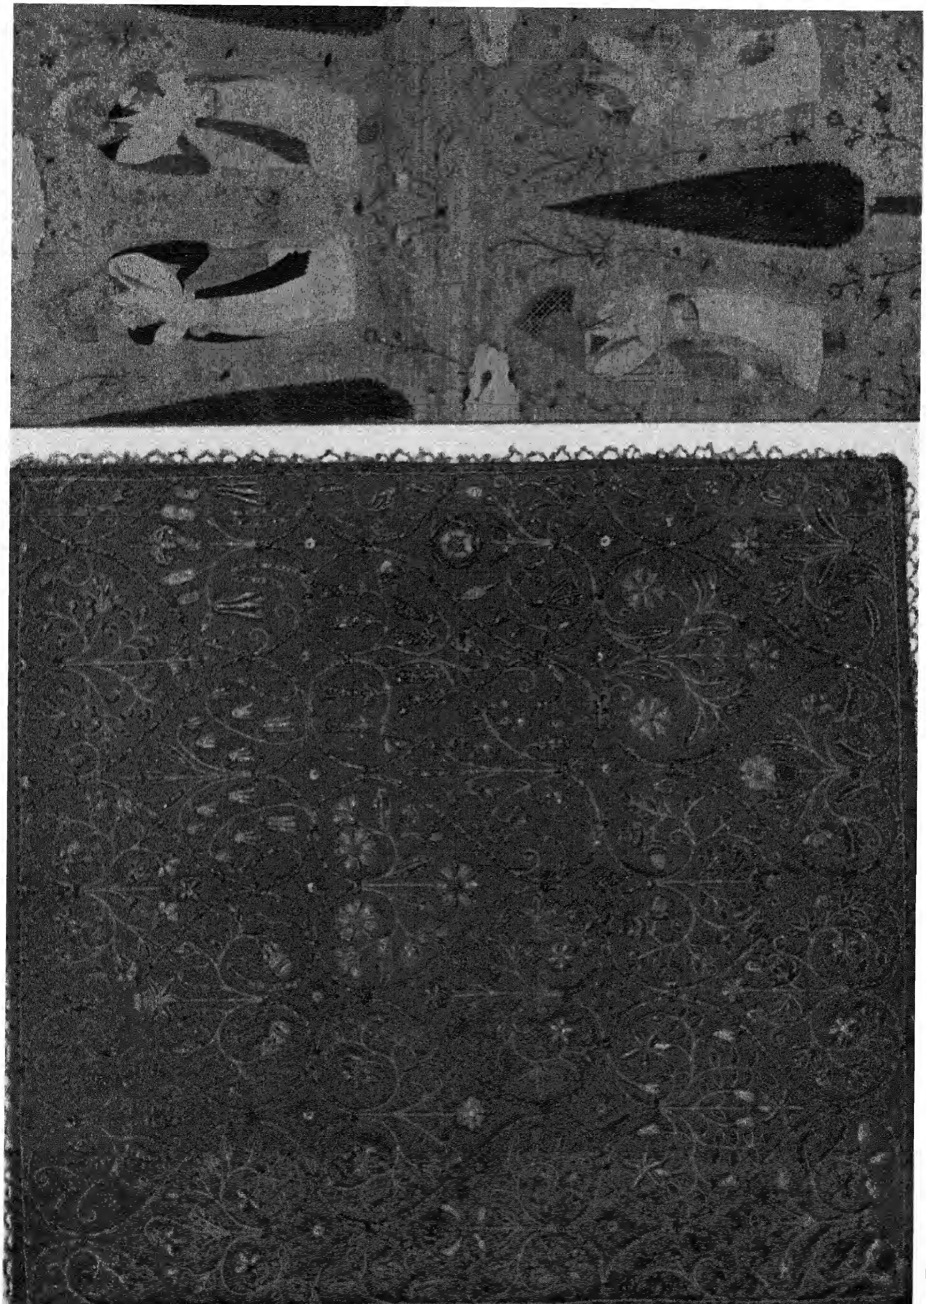
TEXTUAL CRITICISM, a general term given to the skilled and methodical application of human judgment to the settlement of *texts*. By a "text" is to be understood a document written in a language known, more or less, to the inquirer, and assumed to have a meaning which has been or can be ascertained. The aim of the "textual critic" may then be defined as the restoration of the text, as far as possible, to its original form, if by "original form" we understand the form intended by its author

Texts may be either *autographs* or they may be *transmitted* texts; these, again, being *immediate copies* of autographs or *copies of copies* to any degree

Autographs (which may be taken to include whatever, though not actually in the writing of its author, has been revised and attested by him) are not exempt from the operations of textual criticism Editors of journals remove the slips of the pens of their contributors; editors of books, nowadays usually in footnotes, the similar lapses of their authors With this branch of textual criticism, however, modern scholarship is not largely concerned Not so with *immediate copies* Textual criticism is called upon to repair the mischief done to *inscriptions* (texts inscribed upon stones) by weathering, maltreatment or the errors of the stone-cutter Any great collection, such as the *Corpus* of Latin inscriptions, will show at once its activity and ability in this direction

The chief field of textual criticism is elsewhere The texts of the older authors which have come down to us were written for the most part not on stone but on papyrus, parchment or other perishable material Of these several copies had to be made, both by way of prevention against the wear and tear of use and as a means of satisfying the desire of other persons than the original possessor to be acquainted with their contents Had the copies made of ancient writings been mechanical reproductions of the originals, such as the photographic facsimiles of modern times, there would have been little here for textual criticism to do The ancient texts have not come to us in this way, but through copies made by the human hand directed more or less by the human intelligence. Now a copy made thus can in no circumstances be a quite exact rendering of that from which it is copied or its *exemplar* A copy, *qua* copy, can never be the equal of the exemplar, and it may be much its inferior. This deterioration increases with the number of successive copyings Let us suppose that from a text which we will call "A" a copy has been made which we will call "B," and from this again a copy which we will call "C." If the copyist of "B" goes wrong once and the copyist of "C" twice in a hundred times, then, assuming that there is no coincidence or cancelling of errors, the relative correctness of the three texts, "A," "B," "C" will be 100 (absolute correctness), 99 and 97·02 If "C" had made his copy direct from "A," his percentage would have been 98 The importance of this must be borne in mind when we are dealing with *transmitted texts,* which have passed through many stages of copying.

The first step towards restoration of a text is the examination of the evidence upon which it is or is to be based. This begins with the investigation of its transmitted form For this we have usually to rely upon *manuscripts* (mss) By manuscripts (*q v*) we understand copies of the text made before the art of printing came into general use. These may be either *extant* or *non-extant* The evidence of extant manuscripts must be ascertained by *collation* To collate a manuscript is to observe and record everything in it which may be of use towards determining what stood in the source or the sources from which it is derived. A manuscript is not usually a clean or single piece of writing; it is commonly found to contain alterations by erasure, addition or substitution. Such alterations may be due to the writer or writers of the ms., called the *scribe* or *scribes*, or to some other person or persons (for there may be several) called *correctors* The relative importance of these corrections may be very different. Hence we must distinguish the different *hands* which have been at work on the manuscript. Account must also be taken of the number of lines



BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM

EXAMPLES OF ENGLISH AND PERSIAN EMBROIDERY

1. Satin cover with embroidery in gold thread and silk. English, late 16th century
2. Velvet brocade panel on a gold thread ground. A courtier in a garden. Persian, late 16th century

PERSIAN EMBROIDERED HANGING OF THE 19TH CENTURY

Hanging for a niche. Field, olive brown; spandrels, white; broad border, dark blue; three narrow borders, red; grounds, white and blue; all woven separately and sewed together. The decoration consists of many coloured pieces of woollen cloth set into the ground, outlined and connected to form patterns by chain stitching in silk thread. It is backed with printed cotton. Size: 75 in. x 50 in.

TEXTILES AND EMBROIDERIES

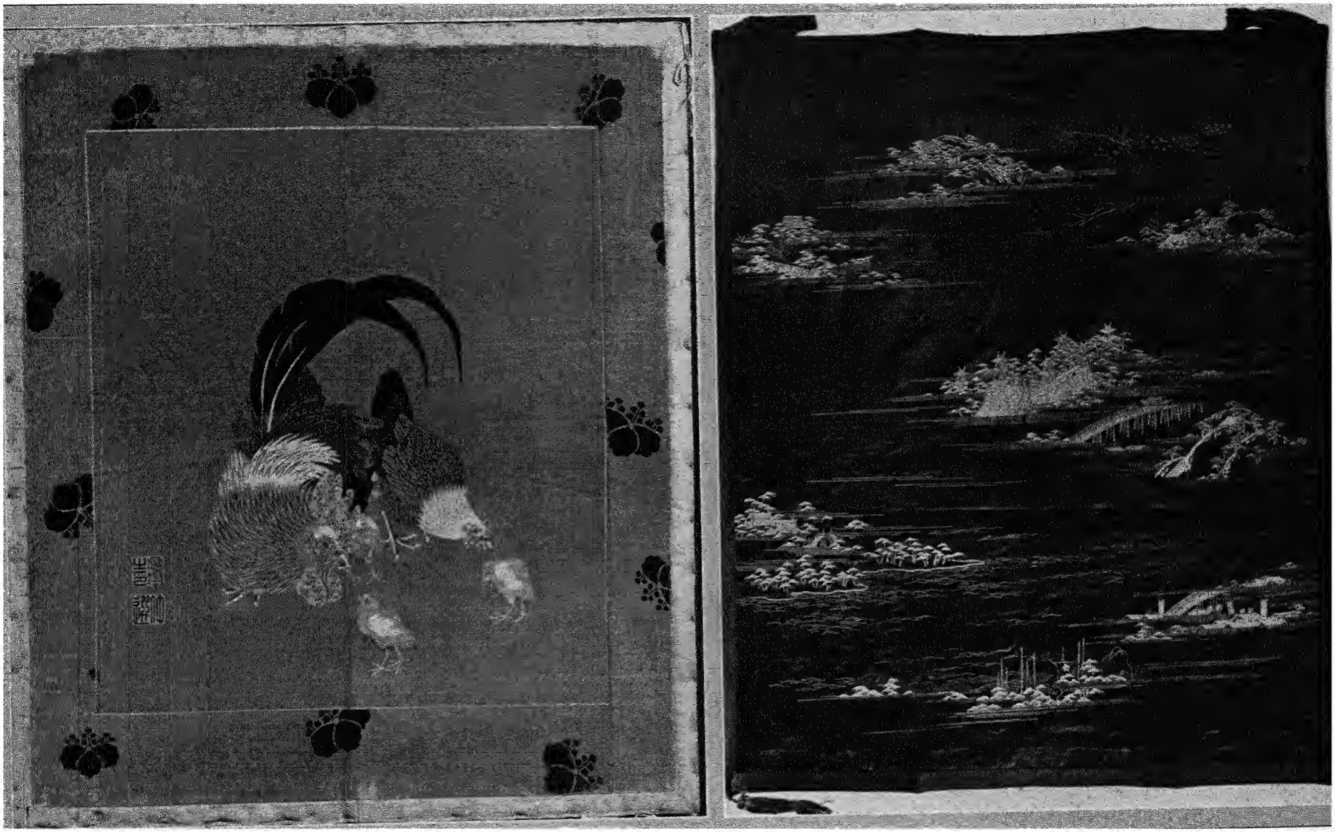
INDIAN PALAMPORE OR BED-COVER

Palampore of elaborate design with peacocks and various geometrical figures. Indian palampores are usually of a heavy type of material and are extensively used in India for bed coverings



JAPANESE COVERS

1. Japanese cut and uncut velvet; fowls with their chicks; the plumage rendered in cut and uncut pile, 19th century
2. Embroidered satin cover of the type usually used for covering a ceremonial present. Japanese landscapes are used in this design, 19th century

ENGLISH EMBROIDERY

1. Front view of an English embroidered chasuble of opus anglicanum of the first decade of the XIV. century, with figures of apostles under arcading
2. Back view of the same chasuble with scenes from the life of the Virgin—the chasuble which is embroidered in gold thread and silk on red velvet has been made from a cope

in each page, the number of pages in each quire, of gaps or lacunae in the manuscript, and so forth. The work cannot be considered complete till all the extant manuscripts have been collated or at least examined When this is done we shall have the materials for pronouncing a judgment upon the text as *directly transmitted*. Perhaps there is only one extant MS. of the text, as in the case of the *Mimes* of Herodas and the *Annals* and *Histories* of Tacitus Then this part of our work is done. But often we have to take account of a number of MSS whose respective claims to attention we must determine. In the first place we shall discard all MSS derived by copying *from other extant MSS* If a MS is immediately or ultimately derived by copying from another MS, it cannot tell us anything that we do not know already if this copied MS is known to us But how can we tell that a MS is so derived? It must be later than the other MS, *and* the similarity between them must be such as to permit of no other explanation In the absence of explicit dates the relative age of MSS is often hard to determine, hence the criterion of unmistakable resemblance is one of especial importance. If the MSS agree in singular though trivial mistakes, if they omit, apparently without motive, words and passages which other MSS preserve, we shall be safe in pronouncing that there exists a close bond of connexion between them; and if one of them shows errors which, though strange in themselves, are quite intelligible when we see what stands in the other, then we conclude that the second is that from which the first is derived For the proper consideration of such points a personal examination, *autopsy*, of the MSS or of facsimiles of them, is often indispensable It was thought at one time that a MS of the Latin poet Propertius at Naples (*Neap* 268) might have independent value as an authority for the text. But its claims were disposed of when (amongst other facts) it was observed that at book iv 8, 3, the MS with which it most closely agreed (F, No 36, 49 in the Laurentian Library) had a gap at the beginning of the line and only the end words "vetus est tutela draconis," with the marginal note "*non potuit legi* in exemplari hoc quod deficit," ("what is missing could not be read in the original") and that *Neap.* 268 gives the line as follows, "*non potuit legi* vetus est tutela draconis"

Accident apart, *identity of reading implies identity of sources.* The source of a transmitted reading may undoubtedly be the author's autograph; but if not, then it is some MS in the line of transmission The peculiar resemblances of two MSS, though not sufficient to warrant the derivation of either from the other, may be sufficient to establish some connexion between them. From the axiom which has just been cited it follows that this connexion can be due only to community of source, and we thus arrive at the idea of *families of MSS* Suppose that a text is preserved in seven MSS, A, B, C, D, E, F, G If we find that of these A stands apart, showing no great similarity to any of the other six, while B, C, D on the one side, and E, F, G on the other, much resemble each other though differing considerably from the rest, we may express this by saying that B, C, D form a "family" descended from a hypothetical common "ancestor" which we may call X, and E, F, G another "family" descended from a hypothetical "ancestor" which we may call Y. The readings of X which can be deduced from considering the agreements in B, C, D will be of higher antiquity and of greater external authority than any of the readings in B, C, D taken singly. And similarly for the readings of Y and those of E, F, G Nor shall we stop here; but we shall further compare the readings of X and Y with each other and with those of A, and thus deduce the readings of a still more remote ancestor which we may call Z. Z will be the *archetype* of all our existing MSS., and we may embody our results in a *pedigree* of manuscripts with Z as the first ancestor.

If we have done our work properly, the texts that we arrive at for X and for Y will be freer from error than the texts of the separate members of the families B, C and D, and E, F, G respectively, and that of Z freer from error than that authenticated by any existing MS.

The procedure, however, is by no means always so simple. That a text may be improved by the comparison of different MSS. is not a modern discovery. It has long been known, and the knowledge has led to the production of what are known as *conflated manuscripts* or *Misch-codices*. These are MSS. produced by "crossing" or "intermixture." In the following stemma M and N are "mixed" or "conflated" MSS, being formed by the blending of readings from the "pure" or "unmixed" codices A, B and D, E respectively. Intermixture may take place to any extent; and the more of it there has been, the more difficult does it become to trace the transmission of a text. Whether crossing improves a given text or not depends ultimately on the knowledge and the judgment of the crosser; and these will vary indefinitely

Non-extant Manuscripts.—Some of the most valuable of ancient MSS. have disappeared since their discovery in modern times When this has happened we have to rely upon mere copies, many times of inferior quality, or upon the information which old scholars have given us respecting them In this case what we have are not "collations," for the art of collation was not understood till the 19th century, but selections or "excerpts" of readings which we have reason to fear are often imperfect and erroneous Further, it must not be assumed that all readings which are cited as being "*ex vetustis codicibus*" ("from ancient MSS.") are necessarily from older or better MSS. than we now possess, or indeed from MSS. at all. Scholars since the Renaissance have not always been above inventing codices to obtain currency for their own conjectures. The codices of Bosius (1535–80) are just as imaginary as the "old plays" which appear as the source of so many of the quotations that head the chapters of the Waverley novels, and suspicion rests on Barth, Lambinus and others.

Some texts and portions of texts of ancient writers are now known only from printed books. The metrical treatise of Terentianus is now preserved in the *editio princeps* (1497) alone. All known MSS of Silius Italicus have a considerable gap in the 8th book, first filled up on the authority of Jac. Constantius (1503), and not printed with the rest of the poem till the edition of Aldus (1523). By the methodical employment of these means we shall arrive at a text different from any existing one. It will not be the best one, possible or existing, nor necessarily even a good one. But it will be *the most ancient one* according to the *direct line of transmission,* and the purest in the sense of being the freest from traceable errors of copying and unauthorized improvements.

The invention of printing has naturally limited the province of textual criticism, and modified its operations. The writer's autograph, if it is preserved after it has been through the hands of the printer, has seldom more than an antiquarian value. As a source for the text it is superseded by the printed edition, and if there is more than one, then by the latest printed edition which has been revised in proof by the author, or, in certain cases, by his representative; and the task of the textual critic is restricted to the detection of "misprints," in other words, of errors which the compositor (the modern analogue to the scribe) has made in "setting up" the manuscript, and which have escaped the notice of the proof-reader and the author or his representative. If, however, this revision has been neglected or incompetently performed, the number of such mistakes may be considerable.

Another question with which the textual critic of modern authors must be prepared to deal is the relative importance of different editions, each of which may have a *prima facie* claim to be considered authentic. Thus Shakespearian criticism must decide between the evidence of the first folio and the quartos; the critic of Shelley's poems must consider what weight is to be attached to the readings in the posthumous edition by Mrs. Shelley, and in unpublished transcripts of various poems. Where there is great or complicated divergence between the editions, as in the case of Marlowe's *Faustus,* the production of a resultant text which may be relied upon to represent the ultimate intention of the author is well-nigh impossible For the bettering of the *transmitted text* we can call in aids of a partial or subsidiary character which are known in general as *testimonia.* Such are *anthologies* or collections of extracts. The oldest authority for an epithalamium of Catullus (62) is an anthology at Paris written in the 9th century. *Translations* from one language into another may help to fix the reading of the original, or this again that of the translation. In

Shelley's *Prometheus Unbound,* ii. 5, 54:

> Child of Light! thy limbs are burning
> Through the vest which seems to hide them

"limbs" is supported against "lips" (ed. i.) by *membre* in the Italian prose version made by Shelley himself; and similarly in l. 52 "looks" (not "locks") by the rendering *sguardi*. In *direct quotations,* either of passages or single words, and either with or without the author's name, we must be sure that the writer is quoting exactly. *Parodies,* discreetly used, may prove of service in restoring the form of what is parodied or this in restoring the parody. So also *obvious imitations,* especially in a highly imitative literature such as Latin poetry.

The support which a reading gains from the evidence of the directly transmitted text *and* from the auxiliary testimonia may be called its *documental probability*. To restore a text from the documental evidence available we must know and weigh the causes which tend to vitiate this evidence in its various kinds. We shall speak first of those which affect the *direct* transmission of texts. These are either external or internal.

External.—A text may become illegible through damp or constant thumbing; portions of it may be torn away; if it is in book form, leaves or whole quires may be detached and either lost or misplaced. When this has taken place on a considerable scale, the critic is helpless, but minor injuries may sometimes be traced and remedied. The weakest parts of a MS. book were the outer margins; hence the beginnings and the ends of lines, whether of verse or prose, were especially liable to injury. It obviously makes a difference upon which side of a leaf, whether on the verso or the recto, a line was written. Hence the determination of the paging of the "archetype" or parent MS. (as was done for the archetype of Lucretius by Lachmann) has more than a merely antiquarian value. In ancient classical MSS. the first letters of poems in verse and paragraphs in prose usually, and the initial letters of lines in verse occasionally, were written separately and by another person than the scribe (who was called the *rubricator*), and therefore were apt to be omitted. Other external circumstances may prejudicially affect a text. The copy from which Shelley's *Julian and Maddalo* was printed was written on very narrow paper, and the punctuation marks at the ends of the lines were frequently omitted.

Internal.—These errors arise from the default of the scribe or copyist, and, in the case of printed books, the compositor. (For the convenience of the general reader these errors have been illustrated as far as possible from English authors and especially from the poems of Shelley [ed. Hutchinson].) They are very numerous. They may be roughly arranged according to the degree in which the volition of the copyist is absent or present, as involuntary or mechanical, semi-voluntary and voluntary, or again as they affect single signs (letters, figures or symbols), words, lines, or even larger units such as sentences or paragraphs.

Simple Errors of the Eye.—(*a*) Confusions of letters. These are very numerous, and different in different scripts or styles of writing (*see* PALAEOGRAPHY). Thus the Roman letters *E* and *F* are liable to be confused in capital script, but not in cursive *e, f; C, G,* in capitals; *c, e* in the cursive writing called Caroline minuscule, *c, t,* in the angular cursive of the 13th century and later. Texts which have had a long history will often show by the letter-confusions which they exhibit that they have passed through several distinct stages of copying. It is to be observed that two different styles of writing are often found in the same manuscript, the difference being utilized for the purposes of distinction. Thus in Greek cursive MSS. notes were often written in uncials. (*b*) Omissions of letters. (*c*) Shiftings of letters, sometimes by syllables. This is very common in half intelligent or half mechanical copying. In printing we get the disarrangement of type which is known as "pie." (*d*) Confusions of symbols and abbreviations.

(*a*) Examples of confusion of capital letters from Shelley's poems are: *Prometheus,* i. 553, "*M*ark that outcry of despair" for "*H*ark", *Hellas,* 472, "*H*old each to the other in loud mockery" for "*T*old." Of cursive letters: *Marenghi,* 130, "the *dim* ocean" for "the *dun* ocean", *Letter to Maria Gisborne* 126, seq.:

> above
> One chasm of Heaven smiles like the *age* of Love
> On the unquiet world

for "*eye.*" (*b*) *Translations from Goethe's Faust,* sc. ii. 165, "eye" for "ey*ne*" (in spite of the rhyme with 163). (*c*) *Prometheus,* iv. 575, "Neither to change, nor f*la*tter, nor repent," for "f*al*ter." In Latin MSS. we often find a mere jumble of letters. (*d*) Confusion of words through abbreviations is very common in ancient MSS., where they were much employed. At a famous place in the doxology of I. Timothy iii. 16, the MSS. vary between ὅς (or ὅ) and Θεός. In uncial writing OC (ὅς) might easily be miswritten or altered to ΘC (Θεός) or vice versa.

Loss of Letters, Syllables, Words or Lines, through Similarity of Writing: Homoeography.—When similar letters or groups of letters stand next to each other, one of these is liable to be omitted. This is the simplest case and is called *haplography*. An example is Shelley's *Cenci,* v. 4, 136, "whose love *was* [*as*] a bond to all our loves." Similarity operates differently if the similar groups stand in different lines of the exemplar. Then the copyist's eye is apt to slip from the first of two similarly written groups to the second; and he will thus omit all that is between.

Omissions through Simple Negligence.—Groups of letters, words, syllables and lines are often omitted without any contributory cause. Short words or such as are not necessary to the sense are especially prone thus to disappear.

Examples of this are, Shelley's *Prometheus,* iii. i, 70,

> No refuge! No appeal!
> Sink with me [then],

Cenci i. i, 26,

> Respited [me] from Hell! So may the Devil
> Respite their souls from Heaven!

Repetitions: Dittography.—Letters, groups of letters, words and lines may be written twice (or even oftener) instead of once. Other repetitions of words already written and anticipations of words yet to be written are also found, through the scribe's eye wandering into the preceding or the following context. Wherever the word or group of words repeated is not the one that he has just copied loss is liable to occur. *Dittography* is common enough in manuscripts, but is usually detected in reading proofs. In the sole MS. of Cicero's treatise *De Republica,* 2, 33, 57, *secutus* appears as *secututus secutus.* Other kinds of repetition are Shelley's *Witch of Atlas,* 611 *seq.:*

> Like one asleep in a green hermitage,
> With gentle *sleep* about its eye-lids playing

(*sleep* for *smiles* has come from the previous line).

Confusions of Words.—Words are not only changed through confusion of single letters or abbreviations, but also through general resemblance or (a semi-voluntary change) through similarity of meaning. Shelley, *Prometheus,* ii. 2, 53 "There s*t*reams a plume-uplifting wind" for "steams." In Shelley's lines, "When the lamp is shattered," vv. 5–6,

> When the lute is broken,
> Sweet *tones* are remembered not

the printed edition had "notes" for "tones." In Mrs Gaskell's *Cranford,* ch. xiv. (near the end), "The lunch—a hot savoury mutton-chop, and a little of the cold *loin* sliced and fried—was now brought in" is the reading of most if not all the editions; but *loin* should be "lion," the reference being to the pudding, "a lion with currant eyes," described earlier in the chapter.

The same character frequently attaches to *transpositions of words and parts of words.* The copyist does not as a general rule consciously intend a change, but he falls into one through the influence of dominant associations. He substitutes an order of words which, in respect of syntax, metre or rhythm is more familiar to him.

Faulty Divisions of Words.—These will generally imply an exemplar in which the words were without any division or without a sufficient one. Under this head we may class errors which arise from the omission or the insertion of such marks as the apostrophe and the hyphen. Examples of *wrong division* of words are Chaucer's *House of Fame,* iii. 1,975, "Of good or misgovernement"

which should be "mis (*i e*, bad) governement"; Shelley's *Prometheus*, iii. 2, 22, "Round many peopled continents" for "many-peopled," *ib* 26, "the light laden moon" for "light-laden" With this we may class *faulty division of sentences.* Wrong punctuation is a common error and usually easy to correct As an example of mispunctuation we may take Shelley's *Triumph of Life,* 188 seqq.:

> "If thou can'st, forbear
> To join the dance, which I had well forborne"
> Said the grim Feature of my thought "Aware
> I will unfold"

for

> said the grim Feature (of my thought aware)
> "I will unfold."

Grammatical Assimilations.—These are often purely mechanical errors, but they may be semi-voluntary or even voluntary, the copyist desiring to set the syntax right, as for example in Shelley's *Mask of Anarchy,* 280 seq

> the daily strife
> With common wants and common cares
> Which *sow* the human heart with tares,

for *"sows"*

Insertions (or Omissions) of Seemingly Unimportant Words.—These, inasmuch as they must often import some judgment on the sense of the passage copied, will be frequently semi-voluntary if not voluntary Examples are Shelley, *Prometheus,* iii 1, 5 "The soul of man like [*an*] unextinguished fire" So in *Triumph of Life,* 265

> Whom from the flock of conquerors
> Fame singled *out* for her thunder-bearing minion,

"out" seems to be due to the compositor

False Recollections.—The passage which a copyist is reproducing may suggest to him something else and he will write down what is thus in his mind instead of what is before his eyes There is a noteworthy instance in Horace, *Odes,* iii 18, 11 seqq

> festus in pratis vacat otioso
> cum bove *pagus*

where some MSS give "pardus," a reminiscence of Isaiah xi 6, "The *leopard* (*pardus*) shall lie down with the kid"

Incorporation of Marginalia.—The copyist may erroneously suppose that something written in the margin, between the lines or at the top or the foot of the page which he is copying, is intended to be placed in the text The words so incorporated may appear side by side with the genuine reading or they may expel it In Horace, *Odes,* iii 27, 47, "amati cornua *monstri*" (of the bull which carried off Europa), more than one MS has "cornua *tauri,*" an explanation of *monstri* The celebrated passage about the three heavenly witnesses inserted in the Epistle of St John (v. 2) seems to have been originally a comment explanatory of the text.

Transpositions of Lines and Passages.—This kind of transposition is really arrested loss An accidental omission is discovered, and the person responsible, or another, places what is omitted in the margin, at the foot of the page or in some other part of the text, usually adding a mark to show where it ought to have been The next copyist may easily overlook this sign and thus the passage may be permanently displaced

Interpolation.—This is the deliberate alteration of an exemplar by way of substitution, addition or omission, but when it takes the particular form of omission it is naturally very hard to detect Interpolation then always has a motive The most frequent motive is the removal of some difficulty in the sense, expression or metre of the text, and especially obvious gaps or corruptions which the interpolator endeavours to fill or to heal Fraudulent interpolation, whether the fraud be pious or otherwise, does occur, but is comparatively rare The removal or the mitigation of objectionable matter is also occasionally found Interpolation is then a voluntary alteration, but in practice it is often hard to distinguish from other changes.

The usual character of scribes' alterations is well illustrated by a passage in Bacon's *Advancement of Learning,* II xix, "for these critics have often presumed that that which they understand not is false set down as the Priest that where he found it written of St. Paul *Demissus est per sportam* (Acts ix 25) mended his book, and made it *Demissus est per portam,* because *sporta* was an hard word, and out of his reading" Shelley in *Triumph of Life,* 201 seq, wrote

> And if the spark with which Heaven lit my spirit
> Had been with proper *nutriment* supplied,

but the printed editions made it "sentiment"

Deliberate alteration is sometimes due to disapproval of what stands in the text or even to less creditable reasons There is an old and seemingly trustworthy tradition that some lines in Homer's "Catalogue of the Ships," *Iliad,* ii 553–556 and 558, were introduced there to gratify the vanity or ambition of the Athenians Insertions of this or of a similar character may be of almost any length, from a few words to a whole chapter or a complete poem Literary forgery has never set any bounds to itself, and the history of every literature will supply examples of entire works being foisted upon authors and personages of repute

Special Conditions Conducing to Corruption.—The chief of these is strangeness or difficulty in the matter to be copied Proper names, technical expressions, quotations from foreign languages, and frequent change of subject, are all likely to cause difficulty to a scribe and error in his work Careful and continuous regard to the various kinds of errors and defaults that are found in transcription will enable us to judge whether a reading which it is suggested stood in the archetype of our text is likely to have been corrupted to the reading, or readings, which stand in the extant manuscripts or editions If it is, we say of this reading that it is *transcriptionally probable*

Some precautions must be observed First we must rule out any proposal which assumes confusions of letters and abbreviations which are not attested for the particular tradition Secondly, since different scribes are prone to different kinds of error, we must ever bear in mind the particular failings of the scribes responsible for the transmission of our text as these failings are revealed in the *apparatus criticus* Maxims of criticism to which we may here refer are that "harder readings are better than easier" and that "the shorter reading is generally the truer" The first maxim is indisputable, provided we understand by "harder" *harder to the scribe,* and by "easier" *easier to the scribe* The characteristic of scribes' emendations or interpolations is that they are superficial Their mark is that at the time of their making they "combine the appearance of improvement with the absence of its reality" (Westcott and Hort, *New Testament,* i. p 27) The second maxim refers to the well known fact that accretions from marginalia, etc, lengthen and also weaken a text

The virtues of a scribe are *honesty* and *care* (or in a single word *fidelity*) and *intelligence* But it is rare to find these combined in a very high degree, and out of them we can least easily dispense with fidelity Paradoxical as it may seem, the mechanical corruptions of a stupid but faithful copyist may tell us more than the intelligent copyings of a less faithful one At certain epochs in the transmission of literature systematic efforts have been made to improve the transmitted texts, and these efforts have naturally been accompanied by a good deal of emendation both successful and unsuccessful Such an epoch was the revival of Latin and Greek learning in the 15th century, and a modern scholar would for that reason naturally prefer to have a manuscript to work on which was written immediately before this epoch to one which was written immediately after it. The fidelity of a scribe has to be judged chiefly by *internal* tests, and these are best applied to his work in passages where there is no reasonable doubt of the correctness of the transmitted text. But there are two tests of a more objective character that may be used—orthography, and indication of lacunae or other faults in his exemplar. A scribe who preserves in his spelling the traces of a bygone age is probably trustworthy If faithful in small things, he is likely to be faithful in great A scribe again who scrupulously records the presence of a lacuna or illegibility in what he is copying, inspires us with confidence in the rest of his work.

As regards the use of *testimonia*, it may be observed to begin with that their value must depend on the trustworthiness of the texts of the writers from whom they are taken, and further upon that of the text used by the translator, the excerptor or the quoter, about which we can know nothing for certain, though we may sometimes make probable inferences. In the case of quotations we must allow for failures of memory. Many times in the course of his investigations the critic will be confronted with problems which cannot be resolved by considerations of transcriptional or documental probability.

This leads us to consider *intrinsic probability*. By this is meant the likelihood that the writer of our text would at the time of writing have written, or not have written, a particular thing. Two questions which may be separated, though they are not entirely distinct, are here involved What was the meaning of the writer? And how did he express it? The sense may be clear though the words may no longer be determinable. A reading may be impugned on a number of grounds: that it gives no sense or an inappropriate sense; that it involves a usage or an idiom not current at the assumed time of writing, or foreign to the reputed author, or to the style in which he then was writing; that it involves some metrical or rhythmical anomaly; or that the connexion of thought which it produces is incoherent or disorderly. These charges cannot be played off against each other It is no answer to the objection that a reading in some Roman poet makes nonsense to say that its Latinity is perfect or its metre excellent. But they may reinforce each other, and to such corroboration great weight must be assigned

To set the meaning of a passage in a foreign language before us we must frequently have recourse to *translation*. But this method of representation is a very imperfect one, we may easily impose on ourselves and others by strained and ambiguous renderings. A more subtle danger to which we are especially liable in the case of a dead language is that of our acquiescing in a sense which satisfies us but which would not have satisfied the ancient writer. Above all we must avoid applying our own standards of taste, style and morality to the judgment of the text before us The textual critic has no concern with what the writer ought to have thought or said; his business is solely with what he did say or think or might have said or thought Among the legitimate reasons for suspecting the correctness of a text are patent contradictions in a passage or its immediate neighbourhood, proved and inexplicable deviations from the standards for forms, constructions and usages (mere rarity or singularity is not enough), weak and purposeless repetitions of a word (if there is no reason for attributing these to the writer), violations of the laws of metre and rhythm as observed by the author, obvious breaks in the thought (incoherence) or disorderly sequence in the same (double or multiple incoherence) Where the critic has ascertained the earliest form of a reading in his text, he will apply to it the tests of intrinsic probability No part of a text can be considered exempt from this scrutiny, though for a very large part of it, it may be dispensed with

After every such critical examination four conclusions are possible—acceptance, doubt, rejection, or alteration. In other words, a critic may deliberately pronounce that what stands in the text represents what the author wrote or might well have written, that it is doubtful whether it does, that it certainly does not, or, in the last event, that it may be replaced with certainty by something that does In the three first cases his judgment will be governed by considerations of intrinsic probability alone: but in the last it must regard transcriptional probability as well No alteration of a text, or *emendation*, is entitled to approval unless, in addition to providing the sense and diction required, it also presents a reading which the evidence furnished by the tradition shows might not improbably have been corrupted to what stands in the text. These tests, and these alone, are emendations bound to satisfy; but others are often tacitly imposed upon them. Of this the transposition of lines is the most notable example. This kind of change is troublesome to estimate and inconvenient to adopt, as it involves placing passages where we are not accustomed to look for them, but to the question, did the author write the passage here or there? the matter of *our* trouble or inconvenience is wholly irrelevant. There is, however, one class of cases in which no conclusion may be drawn, documental and intrinsic probability both failing us. This is where the alternative readings, neither of which can have come from the other, have equal external support and equal intrinsic merit. Isolated discrepancies of this kind may be due to some accident to our text at a period now beyond our power to trace. Numerous and striking discrepancies may be due to the fact that there was more than one edition or recension of it in early times, or to the author's leaving his work in such a condition that such discrepancies must inevitably gain currency In the case of dramas, different acting editions will give rise to them.

Up to this point all schools of textual criticism are theoretically at least in accord But here begins a divergence which has done more than anything else to discredit the study with the outside world. It emerges because in all judgments on textual matters it is presupposed that they will be acted upon, that a reading accepted will remain in the text, a rejected one obelized, enclosed between brackets or removed, and in this last case something else substituted in its place. Now the "conservative" critic's chief concern is for the safety of the traditional and by preference the transmitted text He urges very rightly that if alteration is carried beyond a certain point it cuts away its own foundation, and so all certainty is destroyed His objective is the minimum of change. And as the need of making a text compels some sort of decision in every case, the "doubtful" readings of the tradition, some of which on the evidence would be doubtfully accepted and others doubtfully rejected, will all appear with the accepteds in the text As to alterations (emendations) that are less than certain, his attitude is clearly if somewhat crudely expressed in the dictum that it is better to leave in the text "what, if not the original reading, is at least the remains of it" The corresponding thesis of the opposite school would be that it is better to present to the reader something which the author might have written than something which he could not: or, in other words, that "stopgaps" should be preferred to débris

An editor of a corrupt and disputed text may reasonably adopt either of two methods of procedure. He may present the text in the purest form which the external evidence warrants, and place all plausible suggestions for its improvement in notes or appendices The text will be faithful but unreadable, and his work will be that of an honest man but of a textual antiquarian, not a textual critic, since he declines the duty of "the restoration of the text, as far as possible, to its original form." By the other method the editor will provide all necessary information about the evidence for the text in the notes of his critical apparatus; but in the text itself he will give whatever in each case is supported by the balance of the probabilities Each and every case he will decide on its own merits and without reference to decisions upon the other cases not now before him Special consideration will be paid to "doubtful" readings, which will be distinguished in his work as "doubtfully accepted" or "doubtfully rejected." Legitimate doubt arises when the evidence *pro et contra* of documental and intrinsic probability is equal, or nearly equal, or when documental probability points strongly to one side and intrinsic probability to another Illegitimate doubt is the uncertainty of the doubter as to whether he has examined the whole of the evidence Such doubt is much more frequently felt than acknowledged, and its effect upon critical work is highly injurious. On the one hand, it is apt to take refuge in an uncritical acceptance of the traditional readings, and on the other hand to produce a crop of hesitant and mutually destructive conjectures which a reader naturally resents as a needless waste of his time

The so-called "conservative text" is neither an antiquarian's text nor a critic's text, but a compromise between the two. When it is conscientiously obtained, it is arrived at by handicapping, more or less heavily, intrinsic probability as compared with documental probability, or by raising the minimum of probability which shall qualify a reading for admission into the text until it is in agreement with the notions of the editor. Both of these procedures are arbitrary in their principle, and liable to be erratic

in their application. The text will suffer whichever course is adopted, and it will suffer the more the more conservative is the editor, as may easily be shown Thus, if we suppose that of two editors of equal competence "A" requires a probability of four-fifths to admit a reading into his text and "B" a probability of three-fifths only, then in all the cases in which the probability lies between these two fractions "B" will be right seven times to "A's" three, while outside these limits there will be no difference between them.

Many persons appear to suppose that decisions upon doubtful points can be avoided by the expedient of leaving the traditional reading in possession of the text The rule is a simple one and easy to apply But owing to the constitution of the human mind it has consequences which possibly they have not contemplated The great works of classical literature are not studied as pathological specimens, and they will be studied the less the more they contain to repel and disquiet the reader If a corruption is left in a text when something might be substituted which would at least, as a "stopgap," give the sort of sense required, then one of two things must happen Either the sense of the passage is blotted out for the reader and the conservation of the corruption is tantamount to the expunging of the rest of the sentence, or else he will obtain the required sense by distorting the meaning of the other constituents of the context until they furnish it So far so good. the requisite sense has been obtained, but the price has now to be paid And the price is that the reader's perception of the signification of the word or words so wrested is dimmed and impaired, and his power of discriminating and understanding them when he meets them again is shot with doubt and error.

It is a weakness of conservative critics to extol interpretation (or exegesis) at the expense of emendation Some have even ventured to say that the successful defence of a passage in a text is a greater service than its successful correction This is not true. The service to the text is the same, what was previously dark being now made clear But the emendation deserves the higher praise as being in most instances the more difficult achievement The fault of the opposite school, on the other hand, is to disparage interpretation and to regard correction as the proper field of a scholar and gentleman This bias is reflected in the maxim that "correction should precede interpretation," which is no more than a half-truth For emendation must inevitably fail unless it express the meaning which the proper interpretation of the passage has shown to be required Further, a corrector may propose the right word with the wrong meaning. Yet the custom is to give the credit of the emendation to him, and not to a successor who has seen what the right sense was and that this was the only word to express it, whereas the first scholar blundered once if not twice, first assigning the wrong sense to the passage and then selecting what (in most cases) would be the wrong word to express it. The proper course would be not to mention the first conjecturer or to mention him only for his error

One of the most vexed questions of textual criticism, and one which divides scholars more perhaps than any other, is the question to what extent admitted imperfections and inconsistencies may properly be left in a text as due to the default of an author rather than of a scribe or compositor. No universal rule is here attainable. Each case must be considered on its merits; and the critic's procedure must of necessity be "eclectic"—an epithet often used with a tinge of reproach, the ground for which it is not easy to discover Two general considerations may be indicated. If the autograph of a work is not accessible, there is no means of distinguishing between the involuntary errors of a scribe and the involuntary errors—"slips of pen"—of an author For these are in fact only scribe's mistakes, the author being his own amanuensis

Passing over this class we come to one about which there may frequently be serious doubt. What is clearly erroneous or faulty may as clearly be intended, and therefore *not* to be removed by the critic. In Chaucer's "Miller's Tale" (3,451, 3,457) *astromie* is used for *astronomie,* and *Noe* and *Noel* (Christmas) confused, "Nowélis flood" (3,451, 3,457), because the speaker is an illiterate carpenter In the "Prologue" to the "Parson's Tale" (10) there is, on the other hand, a mistake of Chaucer's own, which no judicious critic would think of removing, the constellation Libra being said to be "*the moon's* exaltation" when it should be *Saturn's*. But this error in an astrological detail would not warrant us in assigning to the poet the blunder about Jacob and Laban in the same tale (*see* above) Much depends on the precision with which an error can be corrected: wherever there are more plausible ways than one of doing this, the faulty reading must be allowed to remain Collateral as well as direct evidence must be obtained If there is a number of instances where there is faultiness which is hard to remove, it is probable that the evil lies too deep for emendation The author's own carelessness may be to blame, or, as in the case of Virgil and Lucan, he may not have been allowed to put the finishing touches to his work

Certain lapses from grammatical correctness and metrical regularity that we find in the poems of Shelley are undoubtedly due to the author, though the number of these has been reduced (as Mr Buxton Forman has pointed out) with our improved knowledge of the sources of the text Among such lapses we may instance *Prince Athanase* (287),

> The shadow of thy moving wings *imbue*
> Its deserts and its mountains;

"To a Skylark" (80), "Thou lovest—but ne'er *knew* love's sad satiety" The solecism in the Preface to the *Adonais,* "My known repugnance to the narrow principles of taste on which several of his earlier compositions were modelled *prove* at least that I am an impartial judge," would probably have been corrected by the poet if his attention had been called to it, but the two first ones, with others, cannot be thus regarded. We may detect occasional laxity also in his handling of his verse Lines are left unrhymed, or the same word is used in place of another rhyming word

Authority, as already hinted, has properly no place in textual criticism For his facts a textual critic may, and often must, be beholden to others but never for his opinions It adds nothing to the evidence for a reading that it has been approved by a Lachmann or a Madvig or rejected by a Stoeber or a Carutti· and an appeal to names on any such question confuses issues and deters inquiry But inasmuch as there are many persons, including most makers of school editions, who prudently and modestly desire a better road to truth than their own investigations can discover and think thus to find it, it will not be amiss to observe on the one hand that the concurrence of a succession of editors in a reading is no proof and often no presumption either that their agreement is independent or that their reading is right, and on the other that, though independence may generally be granted to coinciding emendations of different scholars, yet from the general constitution of the human mind it is likely that not a few of these will be coincidences in error rather than in truth

As time goes on, textual criticism will have less and less to do In the old texts its work will have been performed so far as it is performable What is left will be an obstinate remainder of difficulties for which there is no solution or only too many. In the newer texts, on the other hand, as experience has already shown, it will have from the outset but a very contracted field

(J P P)

THĀʻALIBĪ [Abu Mansur ʻAbd ul-Malik ibn Mahommed ibn Ismaʻīl uth-Thaʻālibī] (961–1038), Arabian philologist, was born in Nīshāpūr. His most famous work is the *Kitāb Yatīmat ud-Dahr,* on the poets of his own and earlier times, containing valuable extracts (Damascus, 4 vols, 1887) Another work, the *Kitāb Fiqh ul-Lugha,* is lexicographical, the words being arranged in classes It has been published at Paris (1861), Cairo (1867), and Beirūt (1885, incomplete).

For his other works *see* C Brockelmann's *Geschichte der Arabischen Literatur,* vol i. (Weimar, 1898), pp. 284–286

THACKERAY, WILLIAM MAKEPEACE (1811–1863), English novelist, only son of Richmond and Anne Thackeray (whose maiden name was Becher), was born at Calcutta on the 18th of July 1811 His father and grandfather (W R Thackeray) had been Indian civil servants His mother was nineteen

at the date of his birth, was left a widow in 1816, and married Major Henry Carmichael Smyth in 1818. Thackeray went to school in Hampshire, Chiswick, and in 1822 to Charterhouse, still on its ancient site near Smithfield In 1828 he left school to join his mother and her husband at Larkbeare in Devon, near Ottery St Mary, which is the "Clavering St Mary," as Exeter and Sidmouth are the "Chatteris" and "Baymouth" of *Pendennis*.

In February 1829 Thackeray went to Trinity College, Cambridge, and contributed lines on "Timbuctoo," the subject for the Prize Poem (the prize for which was won by Tennyson), to a little paper called *The Snob* James Spedding, Monckton Milnes (Lord Houghton), Edward FitzGerald, and W. H. Thompson (afterwards Master of Trinity) were among his friends. In 1830 he left Cambridge without taking a degree. A visit to Weimar bore fruit in the sketches of life at a small German court which appear in *FitzBoodle's Confessions* and in *Vanity Fair.* In G. H. Lewes's *Life of Goethe* is a letter containing Thackeray's impressions of the German poet On his return to England in 1831 he entered the Middle Temple, and found material for some capital scenes in *Pendennis.* In 1832 he inherited a sum which, according to Trollope, amounted to about five hundred a year. The money was soon lost—some in an Indian bank, some at play and some in two newspapers, *The National Standard* and *The Constitutional.* In *Lovel the Widower* these two papers are indicated under one name as *The Museum,* in connection with which Honeyman and Sherrick of *The Newcomes* are briefly brought in. Thackeray's adventures at play were utilized on three occasions, in "A Caution to Travellers" (*The Paris Sketch-Book*), in the first of the Deuceace narrations (*The Memoirs of Mr. C. J Yellowplush*), and in *Pendennis*, vol. ii chap. v., in a story told to Captain Strong by "Colonel Altamont."

About 1834 Thackeray settled in Paris to study art seriously. He had, like Clive in *The Newcomes,* shown early talent as a caricaturist His pencil was at its best technically in such fantastic work as is found in the initial letters of chapters, and in those drawings made for the amusement of child friends which were the origin of *The Rose and the Ring*

In 1836 Thackeray married Isabella, daughter of Colonel Matthew Shawe. There were three daughters born of the marriage, one dying in infancy The eldest daughter, Anne Isabella married in 1877 (Sir) Richmond Ritchie, of the India Office. She inherited literary talent from her father and wrote several charming works of fiction, notably *Miss Angel* (1875), and subsequently edited Thackeray's works and published some volumes of criticism and reminiscences The younger daughter, Harriet Marian, married (Sir) Leslie Stephen in 1867 and died in 1875. Mrs. Thackeray, to quote Trollope, "became ill and her mind failed her," in 1840, and he "became as it were a widower to the end of his days", she did not die till 1892

In 1837 Thackeray came to London, and became a regular contributor to *Fraser's Magazine* In this in 1841 appeared *The History of Mr Samuel Titmarsh and the Great Hoggarty Diamond,* a work filled with the wit, humour, satire, pathos, which found a more ordered if not a fresher expression in his later works. The characters are full of life; the book is crammed with honest fun, and for pure pathos, the death of the child stands in the company of very few such scenes in English fiction, but *The Great Hoggarty Diamond,* had to be cut short at the bidding of the editor. In 1840 came out *The Paris Sketch-Book*, much of which had been written and published at an earlier date In 1838 Thackeray had begun, in *Fraser, The Yellowplush Papers,* with their strange touches of humour, satire, tragedy, and their fantastic spelling; and this was followed by *Catherine,* a strong story, founded closely on the career of a criminal named Catherine Hayes, and intended to counteract the then growing practice of making ruffians and harlots prominent characters in fiction When *Pendennis* was coming out in serial form (1850) another Catherine Hayes, an Irish singer and famous *prima donna,* was much before the public. Thackeray, thinking of the former and oblivious of the latter Catherine Hayes, caused a great outcry in the Irish press by coupling the name with that of a recently notorious murderer. He afterwards suppressed the passage but the incident is of interest because it explains the initial letter drawn by Thackeray for chap. xv., vol. ii., of *Pendennis.* The drawing is in itself highly comic, but must seem quite meaningless without the key. There soon followed *Fitz-Boodle's Confessions and Professions,* and the *Shabby Genteel Story,* a work interrupted by Thackeray's domestic affliction and afterwards republished as an introduction to *The Adventures of Philip,* which took up the course of the original story many years after the supposed date of its catastrophe. In 1843 also came out the *Irish Sketch-Book,* and in 1844 the account of the journey *From Cornhill to Grand Cairo,* in which was included the excellent poem of "The White Squall." In 1844 there began in *Fraser* the *Memoirs of Barry Lyndon,* called in the magazine "The Luck of Barry Lyndon, a Romance of the Last Century." His latter career is founded on that of Andrew Robinson Stoney Bowes, who married the widow of John, 9th earl of Strathmore.

Thackeray became a contributor to *Punch* within the first year of its existence. John Leech, who was one of the earliest contributors, had been at Charterhouse with Thackeray and the two men were friends through life He made his first hit with *Jeames's Diary,* begun in November 1845, and may be said to have established his reputation by the *Snob Papers* (1846), now known as *The Book of Snobs. "Punch's Prize Novelists,"* another series which Thackeray contributed to the paper, contain some brilliant parodies of Edward Bulwer-Lytton, Lever, Disraeli and others. Owing to differences in political opinion, his connection with *Punch* ended in 1851 Minor but admirable works of the same period are *Legend of the Rhine* (a burlesque of Dumas's *Othon l'Archer*), in George Cruikshank's *Table Book,* edited by Gilbert À Beckett, *Cox's Diary* (on which has been founded a well-known Dutch comedy, *Janus Tulp*), and *The Fatal Boots. Rebecca and Rowena* towers over every other burlesque of the kind. Its taste, its wit, its pathos, its humour, are unmatchable; and it contains some fine songs of a particular sort In 1846 was published, by Messrs. Bradbury and Evans, the first of twenty-four numbers of *Vanity Fair*, the work which placed Thackeray as a novelist of the first rank It was completed in 1848, when Thackeray was thirty-seven years old The charge of cynicism Thackeray has himself met at the end of the eighth chapter, in a passage which is the best commentary on the author's method.

Another accusation brought against the book was that the colours were laid on too thick, in the sense that the villains were too villainous, the good people too goody-goody, the best answer to that can be found by anyone who chooses to read the work with care Osborne is meant to be a poor enough creature, and one whose poorness of character is developed as he allows bad influences to tell upon his vanity and folly The good in him comes out in the beautiful passage describing his farewell to Amelia on the eve of Waterloo, in which passage may be also found a sufficient answer to the statement that Amelia is insipid and uninteresting. So with the companion picture of Rawdon Crawley's farewell to Becky Sharp: who that reads it can resist sympathy, in spite of Rawdon's vices and shady shifts for a living, with his simple bravery and devotion to his wife? As for Becky, there is certainly not much to be said in her defence We know that she thought she would have found it easy to be good if she had been rich, and we know also what happened when Rawdon surprised her alone with Lord Steyne How "she admired her husband, strong, brave and victorious " This admiration is the capital touch in a scene as powerful as any Thackeray ever wrote. The supreme art in the treatment of the character of the brilliant adventuress that Becky was, makes the reader feel her attractiveness, though he knows her evil qualities.

Vanity Fair was followed by *Pendennis, Esmond* and *The Newcomes,* which appeared respectively in 1850, 1852 and 1854. *Esmond* is perhaps Thackeray's capital work. It is undoubtedly one of the greatest of English historical novels. The insolent beauty Beatrix reappears in the *Virginians* as the jaded, worldly, and not unkindly Baroness.

In 1851 Thackeray had written *The English Humourists of the Eighteenth Century,* delivered as a series of lectures at Willis's Rooms in the same year, and re-delivered in the United States in

1852 and 1853, as was afterwards the series called *The Four Georges*. In 1854 was published that delightful burlesque, *The Rose and the Ring*. In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford and in the same year appeared the first number of *The Virginians*, a sequel to *Esmond*. The last number came out in 1859, and in the same year Thackeray undertook the editorship of the *Cornhill Magazine*. This was a task which, as readers of his *Roundabout Paper* "Thorns in the Cushion" will remember, the kindliness and sensitiveness of his disposition made irksome to him, and he resigned the editorship in April 1862, though he continued to write for the magazine until he died In the *Cornhill* appeared *Lovel the Widower*, previously written, with different names for some of the personages, in dramatic form, *The Adventures of Philip* (1861–62); the *Roundabout Papers*, some of his best essays, and (1860–63) the story, unhappily never finished, called *Denis Duval* Among the *Roundabout Papers* is one differing in form from the rest, called "The Notch on the Axe—a Story à la Mode," an almost perfect specimen of the author's genius for burlesque story-telling *The Adventures of Philip* is in the nature of a sequel to *A Shabby Genteel Story*, contains scenes which rank with Thackeray's best work, there are fine sketches of journalistic, artistic and diplomatic life, but Philip himself is impossible, the character is not drawn at all *Denis Duval*, which reached only three numbers, promised to be a first-rate work in the *Esmond* manner The author died while it was in progress, on Dec 24, 1863 He was buried in Kensal Green, and a bust by Marochetti was put up to his memory in Westminster Abbey

The grace and the apparent spontaneity of Thackeray's verses are beyond question Some of the more serious efforts, such as "The Chronicle of the Drum" (1841), are full of power and instinct with true poetic feeling Both the half-humorous, half-pathetic ballads and the wholly extravagant ones must be classed with the best work in that kind, and the translations from Béranger are as good as verse translations can be, for Thackeray had the true poetic instinct

The books of reference that can be best commended to the student of Thackeray's life and works are Merivale and Marzials' *Life of Thackeray* (1891), R H Shepherd, *Bibliography of Thackeray* (1880), C P Johnson, *The Early Writings of Thackeray* (1888), Charles Whibley's *Thackeray* (1905), a critical commentary, the edition of Thackeray's Works with biographical introductions (1897–1900), by his daughter, Lady Ritchie, the *Life of Thackeray* ("English Men of Letters Series," 1899) by Anthony Trollope Trollope showed in his own Autobiography far more appreciation of Thackeray's great qualities than is apparent in the Life *Letters of W M Thackeray and Edward Fitz-gerald* (1912), Rt Hon Sir A C Lyall, *Studies in Literature and History* (1915), Trowbridge Hall, *Illustrated Catalogue of 1st Editions* (New York 1921); E B Chancellor, *The London of Thackeray* (1923); Anne Thackeray Ritchie, *Letters, with 42 additional letters of W M. Thackeray* (1924), ed by her daughter, H Ritchie.

THAÏS, a Greek courtesan, who lived during the time of Alexander the Great She accompanied him on his Asiatic campaign, and is chiefly known from the story which represents her as having persuaded the conqueror to set fire to the city of Persepolis This anecdote forms the subject of Dryden's *Ode to Saint Cecilia's Day*. But its authenticity is doubtful, since it is based upon the authority of Cleitarchus, one of the least trustworthy of the historians of Alexander Thaïs subsequently became the wife of Ptolemy Lagus, king of Egypt

See Diod Sic xvii 72; Plutarch, *Alexander*, 38; Athenaeus xiii. 576, 585, Quintus Curtius v. 7.

THALE, a town in the Prussian province of Saxony, situated at the northern foot of the Harz Mountains, 8 m. S W. of Quedlinburg by rail, at the entrance to the gorge of the Bode. Pop. (1923) 13,743 It is largely frequented as a summer resort and for its saline springs It is a manufacturing centre, its chief products being tin wares and tiles, and it has iron foundries, sawmills and lignite mines

THALER, a silver coin formerly circulating in North Germany. When the mark was first introduced in 1871, all other silver coins were withdrawn from circulation, but the thaler was of such outstanding importance that this course proved impossible It was thus enacted that the thaler should remain unlimited legal tender at three marks per thaler This system lasted till 1908.

THALES OF MILETUS (640–546 B C), Greek physical philosopher, son of Examyus and Cleobuline, is said to have been of Phoenician extraction, but was more probably a native Milesian of noble birth Thales was certainly a Greek and not a Phoenician. He was chief of the seven "wise men" of Greece; and in later times amongst the ancients his fame was remarkable This name (σοφός) was given on account of practical ability, and Thales had been occupied with civil affairs The advice which he gave to his fellow-countrymen "before Ionia was ruined"—"that the Ionians should constitute one general council in Teos, as the most central of the twelve cities, and that the remaining cities should nevertheless be governed as independent states" (Herod i. 170) —is noteworthy. The appellation "wise man" was conferred on him not only for his political sagacity, but also for his scientific eminence (Plut *Solon*, c 3)

He became famous by his prediction of the eclipse of the sun of May 28, 585 B C. Herodotus's account of it (i 74) contains two statements —(1) the fact that the eclipse did actually take place during a battle between the Medes and the Lydians, that it was a total eclipse, that it caused a cessation of hostilities and led to a lasting peace between the contending nations; (2) that Thales had foretold the eclipse to the Ionians, and fixed the year in which it actually did take place Various dates—ranging from 625 B C to 583 B C—have been assigned by different chronologists to this eclipse; but, since the investigations of Airy[1], Hind[2], and Zech[3], the date determined by them (May 28, 585 B C) has been generally accepted (for later authorities *see* ECLIPSE and ASTRONOMY) This date agrees nearly with that given by Pliny

Thales's fame amongst the ancients must have been largely due to this achievement Thales seems to have left no works (but *see* Diog Laer. i. 23) Many anecdotes are related of him, from some of which it would appear that he was engaged in trade (Plutarch, *Solon, c.* 2) Of the fact that Thales visited Egypt, and there became acquainted with geometry, there is abundant evidence Hieronymus of Rhodes (ap Diog Laër i 27) says, "he never had any teacher except during the time when he went to Egypt and associated with the priests "[4]

But the important feature of Thales's work was that he founded the geometry of lines, which was essentially abstract in its character. The Egyptian priests only had the geometry of surfaces, a sketch of that of solids, *i e*, a geometry consisting of some simple quadratures and elementary cubatures, obtained empirically Thales introduced *abstract* geometry, the object of which is to establish precise relations between the different parts of a figure, so that some of them could be definitely found by means of others This was a phenomenon quite new in the world

The following discoveries in geometry are attributed to Thales —(1) the circle is bisected by its diameter (Procl *op cit* p 157), (2) the angles at the base of an isosceles triangle are equal (*Id* p. 250); (3) when two straight lines intersect the vertically opposite angles are equal (*Id* p 299); (4) the angle in a semicircle is a right angle[5], (5) the theorem Euclid i 26 (Eudemus, Procl *op cit* p 352) Two applications to practical problems are also attributed to him —(1) the determination of the distance of a ship at sea; (2) the determination of the height of a pyramid by means of the length of its shadow the shadow was measured at the hour of the day when a man's shadow is the same length as himself[6] According to Plutarch (*Sept Sap Conviv* 2), Thales must have known Euclid vi 4, but without the restriction as to the hour of the day Further, we learn that he perfected the

[2] *Athenaeum*, p 919, 1852

[3] *Astronomische Untersuchungen der wichtigeren Finsternisse*, etc, p. 57, 1853.

[4] *Cf.* Pamphila and the spurious letter from Thales to Pherecydes, ap Diog Laer; Proclus, *In primum Euclidis Elementorum Librum Commentarii*, ed Friedlein, p 65; Pliny, *H N* xxxvi 12; Iamblichus, *In Vit. Pythag* 12; Plutarch, *Sept. Sap Conviv* 2, *De Iside*, 10, and *Plac* i 3, 1

[5] This is unquestionably the meaning of the statement of Pamphila (temp Nero), ap Diog Laër i 24, that he was the first person to describe a right-angled triangle in a circle

[6] Hieronymus of Rhodes (Diog. Laër i. 27) and Pliny (*N H* xxxvi 12).

theory of the scalene triangle and the theory of lines[1]. Proclus in his summary of the history of geometry before Euclid, says that Thales introduced geometry into Greece from Egypt, and communicated the beginnings of many propositions to his successors.

From these indications it is difficult to determine what Thales brought from Egypt and what he himself discovered. This difficulty has, however, been lessened since the translation and publication of the papyrus Rhind by Eisenlohr[2]; and we can deduce certain facts from it [1] Thales must have known the theorem that the sum of the three angles of a triangle are equal to two right angles. This inference is made from theorems (4) and (2). We know from Proclus, on the authority of Eudemus, that Euclid i. 32 was first proved in a general way by the Pythagoreans; but, on the other hand, we learn from Geminus that the ancient geometers discovered the equality to two right angles in each kind of triangle —equilateral isosceles, and scalene (Apoll *Conica*, ed. Halleius, p. 9); and the geometers older than the Pythagoreans can only have been Thales and his school The theorem was probably arrived at by induction, and may have been suggested by the contemplation of floors or walls covered with regular triangular, square or hexagonal tiles. [2] We see also in the theorem (4) the first trace of the conception of geometrical loci, which we, therefore, attribute to Thales. It was in this manner that this remarkable property of the circle, with which, in fact, abstract geometry was inaugurated, presented itself to the imagination of Dante:—

> "O se del mezzo cerchio far si puote
> Triangol si, ch'un retto non avesse"—*Par.* c. xiii. 101.

[3] Thales discovered the theorem that the sides of equiangular triangles are proportional. This theorem was probably made use of also in his determination of the distance of a ship at sea.

Let us now consider the importance of the work of Thales. I. In a scientific point of view: (*a*) by his two theorems he founded the geometry of lines, which has ever since remained the principal part of geometry; (*b*) he may be considered to have laid the foundation of algebra, for his first theorem establishes an equation in the true sense of the word, while the second institutes a proportion[3]. II. In a philosophic point of view; we see that in these two theorems of Thales the first type of a natural law, *i. e.*, the expression of a fixed dependence between different quantities, or, in another form, the disentanglement of constancy in the midst of variety—has decisively arisen[4]. III Lastly, in a practical point of view: Thales furnished the first example of an application of theoretical geometry to practice[5], and laid the foundation of the methods of measurement of heights and distances.

As to the astronomical knowledge of Thales we have the following notices:—(1) besides the prediction of the solar eclipse, Eudemus attributes to him the discovery that the circuit of the sun between the solstices is not always uniform[6]; (2) he called the last day of the month the thirtieth (Diog Laër. i 24); (3) he divided the year into 365 days (*Id.* i. 27), (4) he determined the diameter of the sun to be the 720th part of the zodiac[7]; (5) he remarked on the constellation of the Lesser Bear and instructed his countrymen to steer by it [as nearer the pole] instead of the Great Bear (Callimachus ap Diog Laër i 23, *cf.* Aratus, *Phaenomena*, v. 36 *seq*). Other discoveries in astronomy are attributed to Thales but on doubtful authorities He did not know, for example, that "the earth is spherical," as is erroneously stated by Plutarch (*Placita*, iii. 10); on the contrary, he conceived it to be a flat disk The doctrine of the sphericity of the earth, for which the researches of Anaximander had prepared the way, was in fact one of the great discoveries of Pythagoras, was taught by Parmenides, who was connected with the Pythagoreans, and remained for a long time the exclusive property of the Italian schools. (*See* Schiaparelli, I Precursori de Copernico nell' Antichità, 1873.)

Philosophy.—Whilst in virtue of his political sagacity and intellectual eminence Thales held a place in the traditional list of the wise men, on the strength of the disinterested love of knowledge which appeared in his physical speculations he was accounted as a "philosopher" (φιλόσοφος). Thales's "philosophy" is usually summed up in the dogma "water is the principle, or the element, of things"; but, as the technical terms "principle" (ἀρχή) and "element" (στοιχεῖον) had not yet come into use, it may be conjectured that the phrase "all things are water" (πάντα ὕδωρ ἐστί) more exactly represents his teaching. Writings bearing his name were extant in antiquity; but as Aristotle, when he speaks of Thales's doctrine, always depends upon tradition, the writings were probably forgeries.

From Aristotle we learn (1) that Thales found in water the origin of things; (2) that he conceived the earth to float upon a sea of the elemental fluid; (3) that he supposed all things to be full of gods; (4) that in virtue of the attraction exercised by the magnet he attributed to it a soul. Here our information ends Aristotle's suggestion that Thales was led to his fundamental dogma by observation of the part which moisture plays in the production and the maintenance of life, and Simplicius's, that the impressibility and the binding power of water were perhaps also in his thoughts, are by admission purely conjectural Simplicius's further suggestion that Thales conceived the element to be modified by thinning and thickening is plainly inconsistent with the statement of Theophrastus that the hypothesis in question was peculiar to Anaximenes The assertion preserved by Stobaeus that Thales recognized, together with the material element, "water," "mind," which penetrates it and sets it in motion, is refuted by the precise testimony of Aristotle, who declares that the early physicists did not distinguish the moving cause from the material cause, and that before Hermotimus and Anaxagoras no one postulated a creative intelligence

It would seem, then, that Thales sought amid the variety of things a single material cause; that he found such a cause in one of the forms of matter most familiar to him, namely, water, and accordingly regarded the world and all that it contains as water variously metamorphosed; and that he asked himself no questions about the manner of its transformation

The doctrine of Thales was interpreted and developed by Anaximander, Anaximenes, and Heraclitus. The Eleatic Parmenides (*q v*), noted that, when Thales and his successors attributed to the supposed element changing qualities, they became pluralists; they therefore required that the superficial variety of nature should be strictly distinguished from its fundamental unity Hence, whereas Thales and his successors had confounded the One, the element, and the Many, its modifications, the One and the Not-One or Many became with Parmenides matters for separate investigation In this way two lines of inquiry originated On the one hand Empedocles and Anaxagoras, abandoning the pursuit of the One, gave themselves to the scientific study of the Many; on the other Zeno, abandoning the pursuit of the Many, gave himself to the dialectical study of the One. Both successions were doomed to failure; and the result was a scepticism from which the thought of Greece did not emerge until Plato, returning to Parmenides, declared the study of the One and the Many, jointly regarded, to be the true office of philosophy. Thus, meagre and futile as the doctrine of Thales was, all the Greek schools, with the solitary exception of that of Pythagoras, took their origin from it. Not in name only, but also in fact, Thales, the first of the Ionian physicists, was the founder of the philosophy of Greece.

THALLIUM, a metallic chemical element, discovered in 1861 by Sir William Crookes, who, during a spectroscopic examination of the flue-dust produced in the roasting of seleniferous pyrites occurring at Tilkerode in the Harz, observed a green line foreign to all then known spectra. He concluded that the mineral contained a new element, to which he gave the name of thallium, from θαλλός, a green twig. Crookes presumed that his thallium was something of the order of sulphur, selenium or tellurium; but Lamy, who anticipated him in isolating the new element, found it to be a metal. (Symbol Tl, atomic number 81, atomic weight 204·3.)

Chemical Character.—The chemical character of thallium presents striking peculiarities. Dumas once called it the "*Ornithorhynchus paradoxus* of metals" As an elementary substance, it is very similar in its physical properties to lead; it resembles lead chemically inasmuch as it forms an almost insoluble chloride and an insoluble iodide. But the hydroxide of thallium, in most of its properties, comes very close to the alkali metals, it is strongly basic, forms an insoluble chloroplatinate (platinichloride), and an alum strikingly similar to the corresponding potassium compounds. Yet, unlike potassium or lead, it forms a feebly basic sesquioxide similar to manganic oxide, Mn_2O_3

Traces of thallium exist in many kinds of pyrites, as used for vitriol-making The only known mineral of which it forms an essential component is the rare mineral crookesite of Skrikerum, Sweden, which, according to Nordenskiöld, contains 33·3% of selenium, 45·8% of copper, 3 7% of silver, and 17 2% of thallium. The best raw materials for the preparation of thallium are the flue-dusts produced industrially in the roasting of thalliferous pyrites and the "chamber muds" accumulating in vitriol-chambers worked with such pyrites, in both it is frequently associated with selenium The flue-dusts may contain 0·5–3·5% of thallium, but usually do not exceed the lower value

For the extraction of the metal from chamber mud, the latter is boiled with water, which extracts thallium as sulphate From the filtered solution the thallium is precipitated as chloride by addition of hydrochloric acid, along with more or less of lead chloride The mixed chlorides are boiled down to dryness with sulphuric acid to convert them into sulphates, which are then separated by boiling water, which dissolves only the thallium salt. From the filtered solution the thallium is recovered, as such, by pure metallic zinc, or by electrolysis The (approximately pure) metallic sponge obtained is washed, made compact by compression, fused in a porcelain crucible in an atmosphere of hydrogen, and cast into sticks.

Metallic Thallium.—Metallic thallium is bluish white; it is extremely soft and almost devoid of tenacity and elasticity. Its specific gravity is 11·86 It fuses at 302° C; at about 1,300° it boils and can be distilled in hydrogen gas. Its vapour density corresponds to monatomic molecules Its salts colour the Bunsen flame a bright green. When heated in air it is readily oxidized, with the formation of a reddish or violet vapour. When exposed to the air it becomes quickly covered with a film of oxide; the tarnished metal when plunged into water reassumes its metallic lustre, the oxide film being quickly dissolved. When kept in contact with water and air it is gradually converted into hydroxide, TlOH It decomposes water at a red heat, liberating hydrogen and being itself converted into the hydroxide. It is readily soluble in nitric and sulphuric acids, but less so in hydrochloric. It does not combine with hydrogen, but unites directly with the halogens.

Salts.—Thallium forms two series of salts: thallous, in which the metal is univalent; and thallic, in which it is trivalent The thallic salts are, however, much less stable than the thallous. In the thallous series many analogies with lead compounds are observed; in the thallic some resemblance to aluminium and gold.

Thallous hydroxide, TlOH, is most conveniently prepared by decomposing the solution of the sulphate with baryta water. It crystallizes from its solution in long yellow needles, TlOH or $TlOH+H_2O$, which dissolve readily in water, forming an intensely alkaline solution, which acts as a caustic and greedily absorbs carbonic acid from the atmosphere. Unlike the alkalis, it readily loses its water at 100° C and even at the ordinary temperature, to form the oxide Tl_2O, which is black or black-violet *Thallic oxide,* Tl_2O_3, is formed when the metal is heated in air or oxygen at 500–700°, by the action of hydrogen peroxide upon alkaline solutions of thallous salts, or by heating thallous nitrate. It decomposes into thallous oxide and oxygen above 800° The corresponding hydroxide, TlO·OH, is very unstable. A thallothallic oxide, $Tl_2O{\cdot}Tl_2O_3$ or TlO, is also known

Thallous chloride, TlCl, is readily obtained from the solution of any thallous salt, by the addition of hydrochloric acid, as a white precipitate similar in appearance to silver chloride, like which it turns violet in the light and fuses below redness into a (yellow) liquid which freezes into a horn-like flexible mass. It is also formed when the metal is burnt in chlorine. One part of the precipitated chloride dissolves at 0° C in 500 parts of water, and in 40 parts at 100° C. It is less soluble in dilute hydrochloric acid. *Thallous iodide,* TlI, similarly obtained as a yellow precipitate, requires 16,000 parts of cold water for its solution. The yellow crystals melt at 190°, and when cooled assume a red colour, which changes to the original yellow on standing *Thallous bromide,* TlBr, is a light yellow crystalline powder; it is formed analogously to the chloride. *Thallous perchlorate,* $TlClO_4$, and *periodate,* $TlIO_4$, are interesting inasmuch as they, together with several other thallous salts, are isomorphous with the corresponding potassium salts

Thallous carbonate, Tl_2CO_3, more nearly resembles the lithium compound than any other ordinary carbonate It is produced by the exposure of thallous hydrate to carbon dioxide, and therefore is obtained when the moist metal is exposed to the air It forms resplendent monoclinic prisms, soluble in water, The bicarbonate is not known.

Thallous sulphate, Tl_2SO_4, forms rhombic prisms soluble in water, which melt at a red heat with decomposition, sulphur dioxide being evolved It unites with aluminium, chromium and iron sulphates to form "alums" (*q v*) It also forms double salts of the type $Tl_2SO_4(Mg, Fe\ or\ Zn)SO_4\,6H_2O$. *Thallous sulphide,* Tl_2S, is obtained as a black precipitate by passing sulphuretted hydrogen into a thallous solution. It is insoluble in water and in the alkalis, but readily dissolves in the mineral acids.

Thallous nitrate, $TlNO_3$, is obtained as white, rhombic prisms by crystallizing a solution of the metal, oxide, carbonate, etc., in nitric acid Various thallous phosphates are known, *e.g,* $Tl_2HPO_4{\cdot}H_2O$, TlH_2PO_4, Tl_3PO_4, $Tl_4P_2O_7$, etc, they bear a close resemblance to the corresponding phosphates of the alkali metals

Thallic chloride, $TlCl_3$, is obtained by heating the monochloride with chlorine under pressure, or by saturating a suspension of the monochloride in water with chlorine, when anhydrous it is a crystalline mass which melts at 24°. It forms several double salts, *e g,* with hydrochloric acid and the alkaline chlorides. The chlorine is not completely precipitated by silver nitrate in nitric acid solution, the ionization apparently not proceeding to all the chlorine atoms. The mixed chlorides $TlCl{\cdot}TlCl_3$ and $3TlCl{\cdot}TlCl_3$ are also produced by the regulated action of chlorine on the monochloride. *Thallic iodide,* TlI_3, is interesting on account of its isomorphism with rubidium and caesium tri-iodides, a resemblance which suggests the formula $TlI(I_2)$ for the salt, but T. M Lowry and A. J Berry (1928) have shown that it does not give the reactions of a thallous salt, and, when dissolved in methyl alcohol, it behaves as a binary electrolyte, *i e,* as $(TlI_2)I$ or as $Tl[TlI_6]$. *Thallic sulphate,* $Tl_2(SO_4)_3{\cdot}7H_2O(?)$, and *thallic nitrate,* $Tl(NO_3)_3{\cdot}3H_2O$, are obtained as colourless crystals on the evaporation of a solution of the oxide in the corresponding acid The sulphate decomposes into sulphuric acid and the trioxide on warming with water, and differs from aluminium sulphate in not forming alums.

Thallium salts are used in the manufacture of certain optical glasses on account of the high refractive index conferred on the glass. They are all poisonous, having an action somewhat resembling that of lead salts, and are said to have a pronounced depilatory action, but this has also been denied.

Thallous acetylacetone, $C_5H_7O_2Tl$, prepared from an alcoholic solution of acetylacetone and the hydroxide, is of interest On the application of thallium compounds to organic syntheses, *see* R C. Menzies, *J Chem. Soc*, 1924, *et seq.*

Analysis.—All thallium compounds volatile or liable to dissociation at the temperature of the flame of a Bunsen lamp impart to such flame an intense green colour. The spectrum contains a bright green of wave-length 5.351. From solutions containing it as thallous salt the metal is easily precipitated as chloride, iodide, or chloroplatinate by the corresponding reagents Sulphuretted hydrogen, in the presence of free mineral acid, gives no precipitate, sulphide of ammonium, from neutral solutions, precipitates Tl_2S as a dark brown or black precipitate, insoluble in excess of reagent. Thallic salts are easily reduced to thallous by means of solution of sulphurous acid, and thus rendered amenable to the above reactions Thallous chloride can be titrated by potassium iodate in moderately concentrated hydrochloric acid solution.

THALWEG, a land-form term adopted into general usage for the continuous line drawn through the lowest points of a river's valley from its source to its mouth The concave curve thus drawn shows the natural direction of a watercourse.

THAMES, the chief river of England, rising in several small streams among the Cotswold Hills in Gloucestershire Its source is generally held to be at Thames Head, in the parish of Coates, 3 m west of Cirencester, but claims have also been advanced on behalf of the Seven Springs, the head waters of the river Churn, 5 m. south of Cheltenham The length of the river from Thames Head Bridge to London Bridge is 161¼ m and from London Bridge to the Nore, 47¾ m, a total of 209 m. The width at Oxford is about 150 ft, at Teddington 250 ft, at London Bridge 750 ft, at Gravesend 2,100 ft, and between Sheerness and Shoeburyness, immediately above the Nore, 5½ m The height of Thames Head above sea-level is 356 ft, Seven Springs 700 ft., and Lechlade 237 ft. and the average fall below Lechlade is 20 in per mile The Thames forms the boundary between the following counties along its course. Gloucestershire and Wiltshire, Gloucestershire and Berkshire, Oxfordshire and Berkshire, Buckinghamshire and Berkshire, Middlesex and Surrey, and finally, at its estuary, Essex and Kent In the succeeding paragraph the bracketed figures indicate the distance in miles above London Bridge.

The upper course lies through a broad valley. The scenery is rural and pleasant, the course of the river winding. Before reaching Oxford the stream swings north, east and south to encircle the wooded hills of Wytham and Cumnor, which overlook the city from the west The Windrush joins from the north (left) at New Bridge (126¾), the Evenlode near Eynsham (119), and the Cherwell at Oxford (112). Between Lechlade and Oxford the main channel sends off many narrow branches; the waters of the Windrush are similarly distributed, and the branches in the neighbourhood of Oxford form the picturesque "backwaters" The river then passes the pleasant woods of Nuneham, and at Abingdon (103½) receives the Ock from the Vale of White Horse, at Dorchester (95¼) the Thame (left), and it then passes Wallingford (90¾) and Goring (85) The river now bends eastward, and breaches the chalk hills, dividing the Chilterns from the downs of Berkshire From this point as far as Taplow the southern slopes of the Chilterns descend closely upon the river, they are finely wooded, and the scenery is peculiarly beautiful At Pangbourne (80¾) the Thames receives the Pang (right), and at Reading (74½) the Kennet (right) After passing Reading it bends northward to Henley (65), eastwards past Great Marlow (57) to Bourne End (54), and southwards to Taplow and Maidenhead (49¾), receiving the Loddon (right) near Shiplake above Henley Winding in a south-easterly direction, it passes Eton and Windsor (43½), Datchet (41½), Staines (36), Chertsey (32), Shepperton (30) and Sunbury (26½), receiving the Coln (left) at Staines, and the Wey (right) near Shepperton. Flowing past Hampton Court, opposite to which it receives the Mole (right), and past Kingston (20½), it reaches Teddington (18¾). Passing Richmond (16) and Kew the river flows through London and its suburbs for a distance of about 25 m, till it has passed Woolwich. Gravesend, the principal town below Woolwich, is 26½ m. from London Bridge. The estuary may be taken to extend to the North Foreland of Kent. In the tideway the principal affluents of the Thames are the Brent at Brentford, the Wandle at Wandsworth, the Ravensbourne at Deptford, the Lea at Blackwall, the Darent just below Erith, and the Ingrebourne at Rainham, besides the Medway.

The basin of the Thames is of a composite character. Thus, the upper portion of the system, above the gap at Goring, is a basin in itself, defined on the west and south by the Cotswold and White Horse Hills and on the east and north by the Chilterns and the uplands of Northamptonshire. But there are several points at which its division from other river basins is only marked by a very low parting Thus a well-marked depression in the Cotswolds brings the head of the (Gloucestershire) Coln, one of the head-streams of the Thames, very close to that of the Isborne, a tributary of the upper Avon; the parting between the head-streams of the Thames and the Bristol Avon sinks at one point, near Malmesbury, below 300 ft.; and head-streams of the Great Ouse rise little more than two miles from, and only some 300 ft above, the middle valley of the Cherwell The White Horse Hills and the Chilterns strike right across the Thames basin, but almost their entire drainage from either flank lies within it, and similarly a great part of the low-lying Weald, though marked off from the rest of the basin by the North Downs, drains into it through these hills Further, the Kennet continues upward the line of the main valley below the Goring gap, and the Cherwell that of the main valley above it The basin thus presents interesting problems The existence of wide valleys where the small upper waters of the Cherwell, Evanlode and Coln now flow, the occurrence of waterborne deposits in their beds from the north-west of England and from Wales, and the fact that the Thames, like its lower southern tributaries which pierce the North Downs, has been able to maintain a deep valley through the chalk elevation at Goring, are considered to point to the former existence of a much larger river, in the system of which were included the upper waters of the present Severn, Dee and other rivers of the west The question, in fact, involves that of the development of a large part of the hydrography of England

Tamesis and Isis.—The Thames about Oxford is often called the Isis. Caesar (*De Bell. Gall.* v. 11) says that at the time of his invasion of Britain it was called Tamesis In the first statute passed for improving the navigation of the river near Oxford (21 Jac I) it is called the river of Thames, and it was only in a statute of George II. (1751) that the word Isis appears The flow of the Thames varies greatly, according to the season of the year In very dry summers the flow at Teddington has been known to fall as low as 200,000,000 gal per day and as high as 20,000,000,000 gal. in a rainy season Flooding of the surrounding country is not uncommon, and it becomes a serious menace to the low-lying parts of London, where the river is tidal, when flooding coincides with high spring tides. The importance of storage reservoirs is manifest under such conditions of flow, especially bearing in mind the ever increasing needs of the London district The water-supply of London is considered under that heading; it may be noted here that the Thames forms its chief source of supply, but apart from this the corporation of Oxford and two companies in the Staines district have powers to draw water from the river

Throughout the whole of the Thames watershed, and especially in the 3,800 sq m above the intakes of the water companies (at Hampton or in the vicinity), the Thames Conservancy has enforced the requirements of parliament that no sewage or other pollution shall be allowed to pass into the Thames, or any water communicating with it. The Thames is navigable for rowing-boats as far upwards as Cricklade and for barges as far as Lechlade At Inglesham, three-quarters of a mile above Lechlade, the Thames and Severn canal has its junction with the Thames. Barges drawing 3 ft 6 in can now, even in the summer season, navigate from London to Inglesham.

Construction of Locks.—In 1771 an act of parliament was passed authorizing the construction of pound locks on the Thames above Maidenhead Bridge. In pursuance of the powers thus granted, the Thames Commissioners of that day caused locks

to be built at various points above Maidenhead, and between 1810 and 1815 the Corporation of London carried out river works on the same lines as far down the river as Teddington. The works as subsequently maintained by the Thames Conservancy ensure an efficient head of water during the drier seasons of the year, and facilitate the escape of winter floods. The number of locks is 47, including four navigation weirs above Oxford The uppermost lock is St John's, below Lechlade, the lowest is Richmond

The canals in use communicating with the Thames, are the Thames and Severn canal, the Oxford canal, the Kennet and Avon canal from Reading to the Bristol Avon, the Grand Junction at Brentford, the Regent's canal at Limehouse, and the Grand Surrey canal at Rotherhithe. A short canal connects Gravesend with Higham Navigation is also carried on by the Medway to Tonbridge, on the lower parts of the Darent, Cray and Wey. The Woking, Aldershot and Basingstoke canal joins the Wey, but is little used The Wilts and Berks canal, joining the Thames at Abingdon, is disused By means of the Grand Junction and Oxford canals especially, constant communication is maintained between the Thames and the great industrial centres of England The trade on the upper Thames is steady, though not extensive The vast trade on the estuary, which lies within the bounds of the port of London, as well as the bridges over the river in the London area, is considered under LONDON The utility of the river is great in the opportunities for exercise and recreation which it affords to the public, especially to Londoners Rowing boats, sailing boats and motor boats ply its waters There are fixed prices for the passage of the locks During the season regattas take place, of which the Henley Royal Regatta is pre-eminent The Oxford and Cambridge boat-race from Putney to Mortlake on the tideway, the summer eights and the "torpids" at Oxford University, and the school races at Eton and Radley should also be mentioned

In 1857 the Thames Conservancy Board was established Its powers were increased and its constitution varied in 1864, 1866 and 1894, but the creation of the Port of London Authority (*see* LONDON) limited its jurisdiction Fish are abundant, especially coarse fish such as pike, perch, roach, dace and barbel Of trout there are many fine specimens, especially at the weirs The right of the public to take fish freely from the river has been frequently under dispute and to-day fisheries are under the regulation of by-laws made by the Thames Conservancy, which apply to the riparian owners as well as to the public generally These by-laws are carried into effect by officers of the conservators, assisted by the river-keepers of the various fishing associations The principal associations are those at Oxford, Reading, Henley, Maidenhead and Windsor, and the Thames Angling Preservation Society, whose district is from Staines to Brentford

THANA, a town and district in British India, in the Northern division of Bombay The town is on the west of the Salsette creek or Thana river, just where the Great Indian Peninsula railway crosses to the mainland, 21 m from Bombay city, of which it is now practically a suburb Pop (1921) 22,639.

The DISTRICT OF THANA has an area of 3,434 sq m It extends along the coast and is confined between the Western Ghats on the east and the sea on the west, while on the north it is bounded by the Portuguese territory of Damaun and by Surat district, and on the south by Bombay suburban district The district is well watered and wooded, and, except in the north-east, is a low-lying rice tract broken by hills. Most of the hills were once fortified, but the forts built on them are now dilapidated and useless The only rivers of any importance are the Vaitarna and the Ulhas, the former being navigable for a distance of about 20 m from its mouth; the latter is also navigable in parts for small craft There are no lakes; but the Vehar and the Tulsi, formed artificially, supply Bombay city with water. In 1921 the population was 759,916. The staple crop is rice. Fishing supports many of the people, and the forests yield timber and other produce. Salt is manufactured by evaporation along the coast

The territory comprised in the district of Thana (apart from Salsette island, which was acquired in 1782) formed part of the dominions of the peshwa, and was annexed by the British in 1818 on the overthrow of Baji Rao.

THANESAR, an ancient town of British India, in Karnal district of the Punjab, on the river Saraswati. pop (1921) 4,226 As the centre of the tract called Kurukshetra in the Mahabharata it has always been a holy place. The bathing-fair held here on the occasion of a solar eclipse is said to be attended by half a million pilgrims

THANET, ISLE OF, the extreme north-eastern corner of Kent, England, insulated by the two branches of the river Stour, and forming one of the eight parliamentary divisions of the county Pop (1921) 112,597 Its name is said to be derived from Saxon *tene,* a beacon or fire (probably from the number of watch-fires existing on this easily ravaged coast), and numerous remains of Saxon occupation have been found, as at Osengal near Ramsgate. Thanet is roughly oblong in form. its extreme measurements being about 8 m from E to W., and 5 m from N to S The branches of the Stour dividing near Sarre take the place of the former Wantsume, a sea-passage which had diminished in breadth to half a mile in the time of Augustine The Wantsume was guarded by the Roman strongholds of *Regulbium* (Reculver) in the north and *Rutupiae* (Richborough) in the south, and was crossed by ferries at Sarre and Wade With the drying up of this channel and the closing of Sandwich harbour in the 16th century, the present marshlands or level to the south and west of the isle were left The sea-face of Thanet consists mainly of bold slopes or sheer cliffs, and the eastern extremity is the fine chalk headland of the North Foreland with a lighthouse Containing the popular seaside resorts of Ramsgate, Broadstairs, Margate and Westgate, Thanet is served by the S R , and Minster is a junction station of the lines to Ramsgate and Sandwich respectively

THANKSGIVING DAY, in the United States, the last Thursday in November, annually set apart for thanksgiving by proclamation of the president and of the governors of the various States The day is observed with religious services in the churches, and, especially in New England, as an occasion for family reunion The Pilgrims set apart a day for thanksgiving at Plymouth immediately after their first harvest, in 1621; the Massachusetts Bay Colony for the first time in 1630, and frequently thereafter until about 1680, when it became an annual festival in that colony, and Connecticut as early as 1639 and annually after 1647, except in 1675 The Dutch in New Netherland appointed a day for giving thanks in 1644 and occasionally thereafter During the Revolutionary War the Continental Congress appointed one or more thanksgiving days each year, except in 1777 President Washington appointed a day of thanksgiving (Thursday, Nov 26) in 1789, and appointed another in 1795 President Madison, in response to resolutions of Congress set apart a day for thanksgiving at the close of the War of 1812 By 1858 proclamations appointing a day of thanksgiving were issued by the governors of 25 States and 2 Territories President Lincoln appointed the last Thursday of Nov 1864, and each president has followed his example

See F B Hough, *Proclamations for Thanksgiving* (Albany, 1858), W. D Love, *The Fast and Thanksgiving Days of New England* (1895), E H Hughes, *Thanksgiving Sermons* (1924); A G Lloyd, *Thanksgiving School Programs* (1927), Van Buren and Bemis, *Thanksgiving Day in Modern History* (1928), L C Van Derveer, *Thanksgiving Plays and Ways* (1927)

THANN, a town of France, capital of an arrondissement in the department of Haut-Rhin, on the Thur, 16 m by rail N W of Mulhouse Pop. (1926) 6,376 In the course of the World War Thann was taken by the French in 1914, and was bombarded from time to time The fine Gothic church of St Theobald (1351) escaped serious injury, it has a tower (1450–1516) with a beautiful spire Above the town are the ruins of the castle of Engelburg, destroyed by Turenne in 1675 Thann is the seat of a subprefect It has a stone quarry, metal-foundries and manufactories of chemical products, machinery and textiles

THAPSACUS (Tiphsah, modern Kalat Dibse, also called for a short time Amphipolis), formerly an important crossing place on the Euphrates (*q.v.*), about 8 miles below Meskene in 36° N. 38° E. The city seems to have stood on the right bank and on the direct line to Syria. It was used as a centre from which to measure distances by Eratosthenes The earlier crossing place

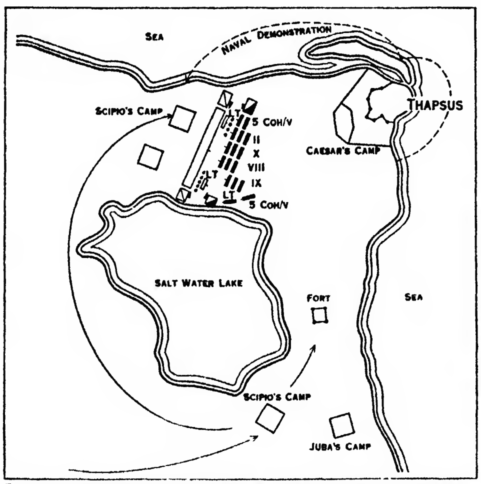
seems to have been higher up the river, but Xenophon, who reports that it was a large prosperous city, forded his army here, and by the time of Alexander there was a bridge of boats.

THAPSUS, a low peninsula, now known as Magnisi, joined by a narrow isthmus to the mainland of Sicily, about 7 m. N N.W of Syracuse. The Athenians used it as a naval station in their attack on Syracuse early in 414 B C A number of tombs contained objects belonging to a transitional stage between the second and third Sicel period, attributable roughly to 1000–900 B C, with a proportion of Mycenean importations

See Orsi in *Monumenti dei Lincei* (1897), vi 89–150

THAPSUS, BATTLE OF (47 B C) After his victory at Pharsalus Julius Caesar followed Pompey to Egypt, where the Pompeians accumulated a large army and were joined by Juba, king of Numidia A battle was fought at Ruspina in which Caesar was almost overwhelmed, after which he moved to Veita and besieged it, withdrew on account of lack of supplies, and, in order to compel Scipio to battle, marched on Thapsus, an ancient city of North Africa in the province of Byzacium (the modern province of Tunis), on the coast more than 100 m north of Carthage Thapsus contained large military stores, was strongly garrisoned and blockaded by Caesar's fleet On Feb. 4, 47 B C. he arrived before the city, and immediately besieged it This drove Scipio into action, for he at once advanced on Thapsus and threw up two entrenched camps, one for his own men and the other for Juba's eight miles south of the city

The manoeuvres which now followed were controlled by a salt water lake, the modern Sebka di Moknine, which lies to the south-west of Thapsus Caesar had entirely surrounded the town, but Scipio considered that it was still possible to relieve it from the south. Caesar had foreseen the likelihood of this move, and had built a strong fort in the centre of the strip of land which separates the eastern margin of the lake from the sea When Scipio ad-



PLAN OF THE BATTLE OF THAPSUS, FEB 47 B C, WHEN JULIUS CAESAR ANNIHILATED THE FORCES OF SCIPIO, FATHER-IN-LAW OF POMPEY THE GREAT

vanced he struck this fort, and being unable to take it turned back and decided to march round the lake and force the northern approach to the city This he did, and constructed two camps north of the lake Though Caesar would have preferred to defer battle until he had taken Thapsus, he now determined to attack Scipio before he had finished his entrenchments. Leaving Asprenas, the pro-consul and two legions to carry on the siege, with the rest of his force he marched against Scipio One half of his fleet he left to continue the blockade, and the other he ordered to sail down the coast, and make a demonstration against Scipio's rear Placing his left on the coast, Scipio drew up his army in three lines with his elephants and light troops in front of his right and left wings, his Numidian cavalry on the left, and the rest of his cavalry and light troops on the right. Advancing on him, Caesar also extended his army into three lines with the II. and X. legions on the right, the VIII and IX. on the left, and five legions in the centre His flanks he covered by five chosen cohorts supported by archers, slingers and cavalry.

As Scipio's camp was but half dug, Caesar's men wished to advance at once Caesar, however, was not over anxious to precipitate the battle because he was largely outnumbered by the Numidian cavalry Whilst he hesitated, the X. legion suddenly sounded the charge which was repeated all down the line. The archers and slingers soon overwhelmed Scipio's elephants with their arrows and stones, driving them back on their own line, where they not only demoralized the infantry but scattered the left wing horse The infantry lines then clinched, fighting each other until sunset, when Scipio's right wing became demoralized This affected the centre, and soon the entire line broke and sought refuge in the half-completed camp, which was speedily captured by a double envelopment of Caesar's wings. Scipio's force was annihilated in an awful slaughter of which Mommsen writes "If the hydra with which they fought always put forth new energies, if the army was hurried from Italy to Spain, from Spain to Macedonia, from Macedonia to Africa, and if the repose ever more eagerly longed for never came, the soldier sought, and not wholly without cause, the reason of this state of things in the unseasonable clemency of Caesar." Fifty thousand corpses were strewn over the battlefield of Thapsus, and among them were several Caesarian officers known as opponents to the new monarchy

In this battle neither strategy nor tactics are remarkable, but what is so is the insubordination of the men, and their growing sense of mastership in the new order which Caesar was creating He wished to found an Empire, and aimed at a complete victory, constantly taking tremendous risks and ignoring the units The soldiers wanted peace, so that they could return to their homes and families At Thapsus a battle was begun between the will of Caesar and the desires of his men, it was slow and progressive, and did not end until Alaric had sacked Rome *See* PHARSALUS. (J F. C F)

THAR AND PARKAR, a district of British India in the Sind province of Bombay Area, 13,636 sq m. Pop. (1921) 396,331 The district is divided into two portions The western part, called the "Pat," is watered by the Eastern Nara canals and the Jamras canal, which constitute the water-systems of the district, and the presence of water has created a quantity of jungle and marsh, the other part, called the "Thar," is a desert tract of rolling sand-hills, running north-east and south-west, composed of a fine but slightly coherent sand To the south-east of Thar is Parkar, where there are ranges of rocky hills, rising to 350 ft above the surrounding level, and open plains of stiff clay This portion contains the ruins of several old temples The principal crops are millets, rice, wheat, oil-seeds and cotton Mirpur Khas (*q v.*) is the administrative headquarters of the district The town lies on the Jodhpur-Bikanes metre-gauge line which connects it with Hyderabad and Rajputana A feeder line runs north from Mirpur Khas to Khadro, and another south to Jhudo. (*See* also INDIAN DESERT.)

THARAUD, JEROME (1874–), French man of letters, was born on March 18, 1874, at Saint-Junien, Haute Vienne, and educated at the collège Sainte-Barbe and the *Ecole normale supérieure* He became a lecturer at the University of Budapest In collaboration with his brother Jean (1877–), he gained the prix Goncourt in 1908, and the *grand prix de littérature* at the French Academy in 1920 The brothers are joint authors (J.-J. Tharaud) of all their works. They excel in the art of story-telling

Their works include, *Dingley, l'illustre écrivain* (1902); *Bar-Cochebas* (1907); *La Maîtresse Servante* (1910); *La Bataille à Scutari d'Albanie* (6th ed., 1913); *La Tragédie de Ravaillac* (1913); *La Vie et la Mort de Déroulède* (1914); *L'Ombre de la Croix* (1917); *Un Royaume de Dieu* (1920); *Quand Israël est roi* (1921); *Rendezvous espagnols* (1925); *La Rose de Saron* (1927) *See* J Bonnerot, *Jérôme*

et Jean Tharaud, leur oeuvre (1927).

THARGELIA. A Greek festival bearing signs of very high antiquity; in historical times part of the cult of Apollo, but quite possibly, indeed probably, older than its arrival in Greece. The name is derived from *θάργηλος*, which signifies an offering of some sort (exact nature and etymology quite uncertain) used at the festival. In Attica, it was held on the 6th and 7th of the month Thargelion, to which it gave its name, the latter date (towards the end of May) was supposed to be Apollo's birthday. On the 6th, certainly at Athens and probably elsewhere, two persons known as *pharmakoi* (magical people, "medicine-men"), who had been chosen for their ugliness, were beaten with plants of a magically purifying value, including squills, being thus filled with good magic, they were led through the city, presents of food being made to them. In classical times they seem to have been regarded chiefly as scapegoats, and some pretence was made of stoning or burning them to death; it is, however, fairly clear that this was not their only significance In Attica they were called *σύβακχοι*; their connection with Apollo is simply that he is the great god of purifications. They occur elsewhere in Ionian ritual

On the 7th, sundry holy things, very likely including an *εἰρεσιώνα* (*see* PYANOPSIA), were carried in procession, and an important musical festival with prizes for the best chorus, was held in honour of Apollo, this is the only rite which we can definitely say is Apolline, and not taken over from some still earlier ceremony It is noteworthy that on the 6th an offering of a ram was made to *Demeter Chloe.* The principal part of the festival was therefore agricultural; as already suggested, Apollo perhaps took it over because it was in part purificatory; it certainly has no intimate relation to his worship.

Farnell, *Cults of the Greek States,* vol iv. p 267 *et seq.* (1907). For the pharmakoi *see* V Gebhard, *Die Pharmakoi in Ionien und die Sybakchoi in Athen* (Amberg, 1926; bibl)

THARRAWADDY, a town and district in the Pegu division of Burma. The town has a station on the railway, 68 m N W from Rangoon Pop. (1921), 3,625 The district has an area of 2,863 sq m The Pegu Yoma range separates it from Toungoo district, and forms the water-parting between the rivers Irrawaddy and Sittang; there are also many small elevations The Irrawaddy is the principal navigable river Teak forests and fuel reserves, cover more than a quarter of the whole area Among the wild animals found in the mountains are elephant, bison and various kinds of feathered game. The rainfall ranges from about 60 to 90 inches. Pop (1921), 492,429, showing an increase of 59,109 in the decade The railway runs through the centre of the district, with ten stations The chief towns are Letpadan (9,901), Gyobingauk (7,666), Zigôn (6,916); Thonzè (6,594); Nattalin (4,898) and Minhla (3,829) The staple crop is rice. The history of the district is identical with that of Henzada (*q.v.*). Tharrawaddy was formed in 1878 out of that portion of Henzada lying east of the Irrawaddy.

THARROS, an ancient town of Sardinia, situated on the west coast, on the narrow sandy isthmus of a peninsula at the north extremity of the Gulf of Oristano, now marked by the tower of S. Giovanni di Sinis. It was 12 m W of Othoca (Oristano) by the coast road, which went on northward to Cornus, and thence to Turris Libisonis. It was of Phoenician origin, but continued to exist in Roman times. It was destroyed by the Saracens in the 11th century. In the necropolis to the south of Tharros many Phoenician tombs have been excavated; they are rectangular or square chambers cut in the rock, measuring from 6 to 9 ft each way Some 3 m to the north is the church of S. Salvatore, with underground rock-cut chambers below it with walls decorated with pre-Christian paintings.

THASOS, an island in the north of the Aegean Sea, off the coast of Thrace and the plain of the river Nestus (Turk. *Kara-Su*). Herodotus (ii. 44. vi. 44–8.) tells of an early Phoenician settlement, of gold mines, and of a temple of Heracles: Thasus, son of Phoenix, gave his name to the island. In 720 or 708 B.C. Thasos received a Greek colony from Paros In a war between the Parian colonists and the Saians, a Thracian tribe, the poet Archilochus threw away his shield. The Greeks owned gold mines also on the mainland From these sources the Thasians drew annual revenues of 200 or even 300 talents. After the capture of Miletus (494 B.C.) Histiaeus, the Ionian leader, laid siege to Thasos The attack failed, but the Thasians built war ships and strengthened their fortifications This excited the suspicions of the Persians, and Darius compelled them to disarm After the defeat of Xerxes they joined the Delian confederacy, but, on account of a difference about the mines and marts on the mainland, they revolted. The Athenians, after a siege of two years, compelled the Thasians in 463 to destroy their walls, surrender their ships, pay an indemnity and an annual contribution (in 449 this was 2½ talents, from 445 about 30 talents), and resign their mainland possessions In 411 B C, during the oligarchical revolution at Athens, Thasos again revolted and received a Lacedaemonian governor, but in 407 the partisans of Lacedaemon were expelled, and the Athenians under Thrasybulus were admitted After the battle of Aegospotami (405 B C), Thasos again fell into the hands of the Lacedaemonians under Lysander who formed a decarchy there, but the Athenians must have recovered it, for it formed one of the subjects of dispute between them and Philip II of Macedonia In the dispute between Philip V and the Romans, Thasos submitted to Philip, but received its freedom after Cynoscephalae (197 B C). After a period of Latin occupation in the 13th century it was captured by the Turks in 1462; it was given by the Sultan Mahmud II to Mehemet Ali (*see* MOHAMMED ALI) of Egypt, and remains the property of the Khedive The capital stood on the N coast, and had two harbours The highest mountain, Ipsario, is 3,428 ft high. Besides its gold, the wine, nuts and marble of Thasos were well known.

The population, 8,000, is distributed in ten villages, mostly at some distance from the sea: for the island suffered from pirates The people are Greek Christians, and do not differ in appearance from the inhabitants of the other Greek islands

For a description of the island and its remains of antiquity, *see* A. Conze, *Reise auf den Inseln des thrakischen Meeres* (Hanover, 1860), for inscriptions *see Inscr Gr* xii 8, the island is fully described by J. ff. Baker-Penoyre in *Journal Hell. Stud.* xxix. (1909).

THATÔN, a town and district in the Tenasserim division of Burma The town is situated below a hill range, 10 m from the sea It was formerly the capital of the Talaing kingdom and a sea-port Pop. (1921), 15,091. The district has an area of 4,831 sq m.; pop (1921) 471,100 The railway from Pegu to Martaban passes through this district Another urban centre in the district is Kyaikto (7,168 in 1921).

THAXTER, ROLAND (1858–), American botanist, was born in Newton, Mass, on Aug 28, 1858, the son of Levi Lincoln Thaxter and Celia Laighton Thaxter (*q v*). He graduated in 1882 from Harvard university, from which he received the degree of doctor of philosophy in 1888. He served as assistant in biology at Harvard from 1886 to 1888, and from 1888 to 1897 as mycologist at the Connecticut agricultural experimental station He was assistant professor of cryptogamic botany at Harvard from 1891 to 1901 and professor from 1901 until 1919, when he became professor emeritus In 1907 he was appointed American editor of the English publication *Annals of Botany* In 1909 he served as president of the Botanical Society of America, and in 1912 was elected member of the National Academy of Sciences

THAYER, ABBOTT HANDERSON (1849–1921), American artist, was born at Boston, Mass., Aug. 12, 1849. He was a pupil of J L. Gérôme at the École des Beaux Arts, Paris, and became a member of the Society of American Artists (1879), of the National Academy of Design (1901), and of the Royal Academy of San Luca, Rome. As a painter of portraits, landscapes, animals and the ideal figure, he won high rank among American artists

Thayer is also well known as a naturalist. He developed a theory of "protective coloration" in animals (*see* COLOURS OF ANIMALS), which has attracted considerable attention among naturalists. According to this theory, "animals are painted by

nature darkest on those parts which tend to be most lighted by the sky's light, and vice versa," and the earth-brown of the upper parts, bathed in skylight, equals the skylight colour of the belly, bathed in earth-yellow and shadow During the World War he worked in England on the development of camouflage. He died at Dublin (N H), May 29, 1921.

See his article, "The Law which underlies Protective Coloration," in the *Annual Report* of the Smithsonian Institution for 1897 (1898), and *Concealing Coloration in the Animal Kingdom* (1910), a summary of his discoveries, by his son, Gerald H Thayer.

THAYER, WILLIAM ROSCOE (1859–1923), American writer, was born in Boston (Mass) on Jan. 16, 1859 After travel abroad with a private tutor, he graduated at Harvard in 1881 He was assistant editor of the Philadelphia *Evening Bulletin,* 1882–85, and then returned to Harvard for advanced study. He was editor of the *Harvard Graduates' Magazine,* 1892–1915. In 1903, at the International Historical Congress at Rome, he represented both Harvard university and the American Historical Association, as also in 1906 at the Italian Historical Congress in Milan He was for almost ten years a member of the Harvard board of overseers In 1918 he was elected president of the American Historical Association and was awarded numerous other scholarly honours He died at Cambridge (Mass) on Sept 7, 1923. Thayer was best known for his works on Italian history, especially *The Dawn of Italian Independence,* (1893), *A Short History of Venice* (1905), and *The Life and Times of Cavour* (1911) His other works include: *Italica* (1908), *The Life and Letters of John Hay* (1915); *Theodore Roosevelt—An Intimate Biography* (1919), *Volleys from a Non-Combatant* (1919); *The Art of Biography* (1920), and *George Washington* (1922) His *Letters* (1926) were edited by C D Hazen.

THAYETMYO, a town and district in the Magwe division of Burma The town is situated on the right bank of the Irrawaddy, opposite Allanmyo Pop (1921) 10,768 The cantonment is no longer used, and the population and importance of Thayetmyo have tended to decrease with the rise of Allanmyo (11,219 in 1921) on the opposite bank of the Irrawaddy There is a special industry of silver work.

The district has an area of 4,750 sq m ; pop (1921) 255,406 The rainfall ranges between 30 and 50 inches On the west is the Arakan Yoma range, and on the east the Pegu Yomas; and the face of the country, where it does not rise into mountains, is everywhere broken by low ranges of hills, many of which are somewhat barren. The chief river is the Irrawaddy, which traverses Thayetmyo from north to south Products are rice, cotton, ground nuts, oil-seeds and tobacco; cutch is also abundant, and he manufacture of the dye-stuff is carried on extensively

THEAL, GEORGE McCALL (1837–1919), British historiographer, was born in Canada in 1837, and became a schoolmaster in Cape Colony in 1858 He developed an interest in the natives and in the history of the country, and after settling a dispute with the Gaika Kafirs on behalf of the Government (1877), joined the Cape Civil Service, in the Native Department. He was also appointed keeper of the archives, and in 1891 was made colonial historiographer, a position which he held until 1905 In 1895 he was commissioned by Cecil Rhodes, then prime minister of Cape Colony, to go to Europe, where he stayed several years examining the Portuguese, Dutch and British archives His research brought to light a mass of unknown or forgotten documents of high value. He died at Wynberg, Cape Province, on April 17, 1919

He published a *History of South Africa (1486–1872)* (5 vols. 1888–93) official *Records of South East Africa* (9 vols. 1898, etc), *Records of Cape Colony, 1793–1827* (36 vols 1897, etc), *The Beginning of South African History* (1902), and many other works, some in Dutch

THEATRE, a building or place furnished with seats and provided with a stage upon which plays or dramatic spectacles are performed; a playhouse In treating fully the various aspects of he theatre, the following sections are presented in this article: (A) Architecture (1) *Development,* (2) *Modern Exteriors and Interiors,* (3) *General Planning,* (4) *Modern Theory of Design;* (B) Direction and Production: (1) *Modern Tendencies,* (2) *Direction and Acting,* (3) *The Actor,* (4) *Theory of Modern Production* (X.)

ARCHITECTURE

DEVELOPMENT

In considering the form of the modern theatre building, its physical aspect, and in tracing the origins and development of that form from the earliest known theatres of Europe, the investigator does well to keep constantly in mind the basic meaning of the word "theatre" From the Greek *θεασθαι*, it means roughly "a place for seeing" In a short survey of the subject it is not necessary to mention pre-Greek theatres, beyond saying that there is no known connection between those of earlier civilizations and the playhouse with which the history of drama in the Western world is generally supposed to start—the theatre of Dionysus at Athens.

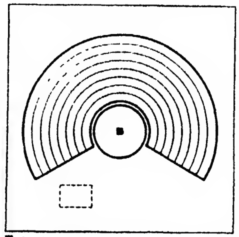

FIG 1—PLAN OF GREEK THEATRE OF EARLIEST TYPE

Greek Theatre.—The first Greek theatres, according to those who have studied the subject most thoroughly, were little more than marked-out dancing-circles, each around an altar, at the foot of hillsides on which spectators stood or sat From this natural form the first *built* theatres took their main outlines a circle or *orchestra* (ὀρχήστρα) for the chorus and actor or actors, and rising tiers of wooden seats, built against a hillside for the spectators These seats extended usually around two-thirds or more of the orchestra, since at this time dancing or movement was more important than acting, and there was no stage for the spectators to face The type of the first built theatres is shown in fig 1 It should be kept in mind, however, that in no period were any two Greek theatres exactly alike, and exceptions to this general type were common

Taking the theatre of Dionysus as an example, one notes that the temple of Dionysus Eleuthereus appeared in relation to the theatre approximately as indicated in the diagram (all within the precinct sacred to Dionysus on the south-eastern side of the Acropolis) One conjecture is that the architectural form of this 6th century temple helped to determine the shape of the stage building which was later to be added at the edge of the circle opposite the seats But the more widely accepted theory is that out of necessity a hut or tent (σκηνή) was added at the edge of the orchestra as a retiring-room for the actors, for changes of costume, etc ; and that the stage building was in all later ages an elaboration of this rude shelter—dressed, in the Greek period, with those beautiful architectural forms with which the Athenians adorned all their important structures.

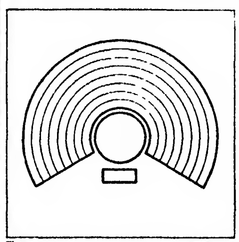

FIG 2—THE THREE-PART THEATRE ARRANGEMENT OF SEATS, ORCHESTRA AND SKENE

Just when this *skene* became truly a stage building, with definite and studied relationship to orchestra and auditorium, is a matter of conjecture As a step in the development of the larger theatre form, we may think of the three parts of the theatre as developing gradually into a set arrangement as shown in fig 2.

Here one sees the accretion of the three features that characterized theatre building through many succeeding centuries: (1) θέατρον, or auditorium; (2) orchestra; and (3) scene, names which persist even to-day. But at this time players appeared only in the orchestra, the scene remaining an architectural background to the action and a practical retiring-house for the actors, structurally separated from the auditorium, by entrances or runways, called παραδοι (Lat. *parodi*).

Such was the theatre form when the 5th century B C dawned, and such it remained, with only slight changes, in all probability, during the period of Aeschylus, Sophocles and Euripides. The architectural features and the height of the *skene* are still only to be conjectured, though recently excavated foundations at Athens indicate clearly the plan and limits of an early stage building, wider than the dancing circle and with ends projecting forward toward the auditorium.

Archaeologists have waged one of their bitterest battles over the question as to when the raised stage made its first appearance, but in the "high" period of Greek drama it is now almost unanimously agreed that there was no platform stage The theatre at Athens had taken this general form, with probably a portico at the front of the scene building, between the *paraskenia* (fig 3).

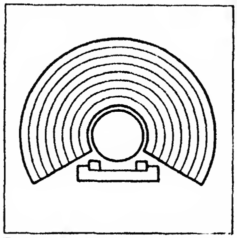

FIG 3—PORTICO ADDED TO FRONT OF SCENE BUILDING

In Greece the theatres were regularly built in hillside hollows, thus avoiding any need to build supporting framework for the tiers of seats, except perhaps at the ends of the "rings" The auditorium was broken by up-and-down aisles with steps, into a number of wedge-shaped "segments" of seats, and sometimes by one or more lateral aisles

The student of later forms may profitably transfer his attention to a point beyond the controversy about the introduction of the raised stage to that time when there was, without doubt, an auxiliary platform for acting The next well-differentiated type of theatre is that in which the stage building is characterized by a high narrow platform on the audience side, called at times the *proskenion* (from which our "proscenium" is derived), and at others the *logeion* or "place for speaking" As acting has become more and more important, the *skene* has developed into a combined architectural background and platform for lifting the actor into clearer view (fig 4) It is to be noted here that the typical Greek separation of auditorium and scene building still exists, although acting now is divided between the orchestra and a stage in our later sense Through the late Greek and the so-called Greek-Roman periods, the narrow *logeion* doubtless went through a gradual widening process

Roman Theatre.—The existing ruins of Roman theatres give absolute evidence regarding the arrangement of the Roman stage and auditorium The two heretofore separate buildings have now been pushed together to form one structure, which is not placed as in Greek times against a hillside hollow, but is erected as a free-standing building supported by arch construction; the orchestra has been contracted to a half-circle, and is now added to the seating space; and all the acting is done on a platform stage, behind which the greatly enlarged *skene* and *paraskenia* rise, with rich architectural ornamentation, to a considerable height The type plan is shown in fig 5. A special type of theatre with wooden platform stage, for comedies, as shown in many extant vase paintings, is disregarded here as having little or no influence on the traditional or persisting form of theatre

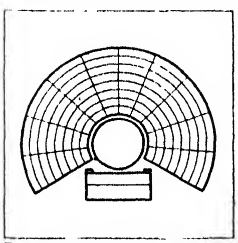

FIG 4—A PLATFORM ADDED AS PART OF THE SKENE

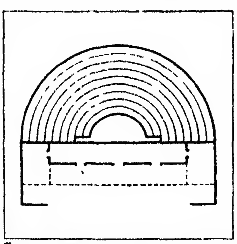

FIG 5—PLAN OF TYPICAL ROMAN THEATRE AS A STRUCTURAL UNIT

In the Roman theatres there were no built-in facilities for scene changing, and it may be assumed that in general there was no painted scenery and no effort to indicate change of locality though elaborate "stage machinery" for trick effects, apparitions, etc, is described by contemporary writers In general, the architecture of the stage wall was the "scene" This wall was regularly pierced by five doorways, three at the back and one in each of the *paraskenia* The large centre door was the "palace entrance" (S CHE)

The larger of the two theatres at Pompeii dates from the Hellenistic period but was thrice reconstructed and it is not clear to what date we are to assign the low stage of Roman pattern Probably it belongs to the earliest period of the Roman colony at Pompeii founded by Sulla 80 B C The theatre of Pompeii is said by Plutarch to have been copied from that of Mytilene which suggests that the Roman theatre was derived from a late Greek model and this is made probably by the existence of transitional forms

During the Republican period the erection of permanent theatres with seats for the spectators was thought to savour of Greek luxury and to be unworthy of the stern simplicity of Roman citizens Thus in 154 B C Scipio Nasica induced the senate to demolish the first stone theatre which had been begun by C Cassius Longinus Even in 55 B.C when Pompey began the theatre of which remains still exist in Rome he thought it wise to place a shrine to Venus Victrix at the top of the cavea, as a sort of excuse for having stone seats below it—the seats in theory serving as steps to reach the temple This theatre which was completed in 52 B C is spoken of by Vitruvius as "the stone theatre" *par excellence:* it is said by Pliny to have held 40,000 people, but Huelsen has shown that this statement was exaggerated and estimates the number of spectators at between 9,000 and 10,000 It was also used as an amphitheatre for the bloody shows in which the Romans took greater pleasure than in the intellectual enjoyments of the drama At its inauguration 500 lions and 20 elephants were killed by gladiators Near it two other theatres were erected, one begun by Julius Caesar and finished by Augustus in 13 B C under the name of his nephew Marcellus and another built about the same date by Cornelius Balbus Little remains of the latter, but the ruins of the theatre of Marcellus are among the most imposing which now exist in ancient Rome

A long account is given by Pliny of a most magnificent temporary theatre built by the aedile M Aemilius Scaurus in 58 B C It is said to have held the incredible number of 80,000 people and was a work of most costly splendour. Still less credible is the account which Pliny gives (H N xxxvi 116) of two wooden theatres built by C Curio in 50 B C which were made to revolve on pivots so that the two together could form an amphitheatre in the afternoon after having been used as two separate theatres in the morning.

All Roman provincial towns of any importance possessed at least one theatre and many of these are partly preserved Covered theatres were sometimes built, whether on account of climatic conditions (as at Aosta) or more commonly for musical performances These latter were generally called *Odea* (a place for singing) The best preserved is the Odeum of Herodes Atticus, at the south-west angle of the Athenian Acropolis, which has a semicircular orchestra It was built in the reign of Hadrian by Herodes Atticus Its cavea which is excavated in the rock, held about 6,000 people, it was connected with the great Dionysiac theatre by a long and lofty porticus or stoa of which considerable remains still exist, probably a late restoration of the stoa built by Eumenes II of Pergamum It was also a common practice to build a small covered theatre in the neighbourhood of an open one, where performances might take place in bad weather. We have an example of this in Pompeii The Romans used scenery and stage effects of more elaboration than did the Greeks Vitruvius (iii. 7) mentions three sorts of movable scenery—(1) for the tragic drama, facades with columns representing public buildings, (2) for comic plays, private houses with practicable windows and balconies such as are shown on Graeco-Roman vases of the latest type, with

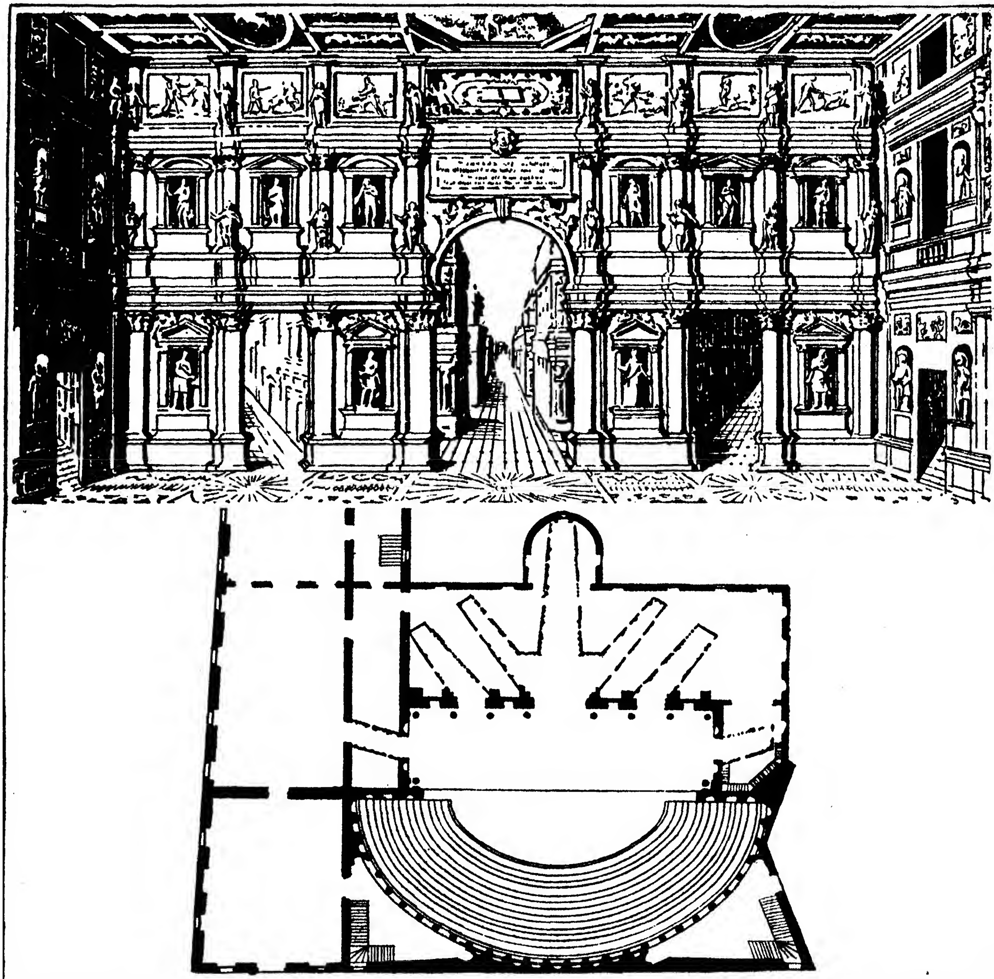

FIG. 6.—PLAN AND STAGE WALL OF THE THEATRE OF THE OLYMPIAN ACADEMY, VICENZA, ITALY; SOMETIMES CALLED THE PALLADIAN THEATRE AFTER ITS FAMOUS ARCHITECT, ANDREA PALLADIO (1518–1580). IT PRESERVES THE ROMAN FORM WITH THE FIVE CLASSIC DOORWAYS AND PROVIDES FOR INTRODUCING SCENERY (NOT AS YET CHANGEABLE)

aintings of burlesque parodies of mythological stories, and (3) or the satyric drama, rustic scenes, with mountains, caverns and rees. (X.)

Renaissance Theatre.—The classic theatres were disused after toman civilization faded, but it was the classic theatre that deermined the form of the playhouse built by the learned academies 1 the cities of Renaissance Italy, and they were the links between he ancient theatre and that of to-day. At Vicenza, the Renaisance theatre of the Olympian academy, sometimes called the 'alladian theatre after its famous architect, still exists, with all :s distinctive architectural features and ornament intact. It is, 1 effect, a small Roman theatre roofed over and made more comact, with typical Renaissance modification of Roman motifs in he decoration. The stage wall is heavily encrusted with archiectural ornamentation and statuary, and the five classic doorays are in orthodox position. One addition, made by Scamozzi in 1585, links this classic stage with the theatres of later times. In that year were constructed the vistas or "perspectives" behind the five doorways of the stage wall, forming the earliest "makebelieve" scenes that have been preserved for posterity. (Already the mystery and miracle stages had in cases been characterized by a combination of half-formed architectural "stations" and realistic localized scenes like the famous "Hell-mouth"; and the court masques were being staged with picture scenes, including the "perspective" type.) The Roman-type building and the added vistas at Vicenza form a plan as shown in fig. 6.

The picture scenes were not yet designed as localized backgrounds for the action so much as an added spectacular attraction, in the Italian masques, and at first the "new style" settings had little effect on the form of the classic-revival playhouses; but the appeal of such pretty playthings could not be long denied, and the modern playhouse emerged where the two currents met. Thus

EXPRESSIONISM AND CONSTRUCTIVISM IN MODERN STAGE SETTINGS

1. Design by Ernest DeWeerth for the auditorium and stage of Triarts Temple, intended for the production of performances combining music, lighting and movement. The figure of the man (centre) merely gives scale-background to an elaboration of Thomas Wilfred's colour organ which lights the high plastic dome
2. Design by Ernest DeWeerth for "Medea." The shadows cast on the background are done by a second cast and show what passes through the mind of Medea throughout the play. In this instance they illustrate the spirit of the children she is about to kill
3. First scene of "Rheingold" designed by Charles Ricketts, R.A., in 1908. The lightest colour shown in the photograph is pale emerald green. The upper part of the pillar has touches of crimson lake, flame colour and buff, gradually merging into emerald and grass green. There are small parts of brilliant emerald green and ultramarine throughout the sketch. The darkest tone, a very dark green with a mixture of brown, is produced by a sepia or vandyke ground colour which is allowed to show through the various coats of body colour
4. Design by Ernest DeWeerth for the speech of Mark Antony in "Julius Caesar." Light is concentrated on the principal figure, and the mob below is amplified by the shadows thrown on the backdrop
5. Design by Ernest DeWeerth for "The Trojan Women"
6. Design for "Oberon," as produced at the Royal Opera House, Stockholm

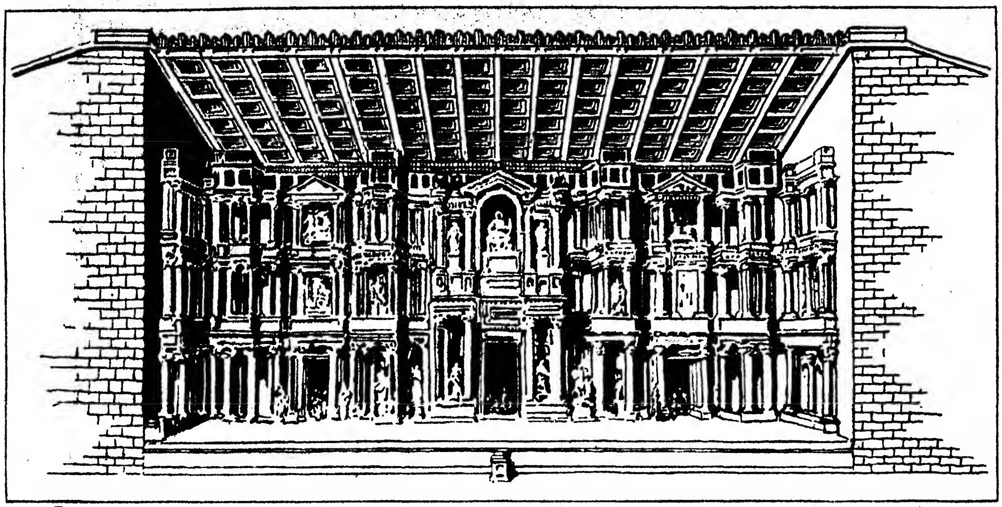

FIG. 7.—BACKGROUND OF THE ROMAN STAGE SHOWING THE NARROW CENTRAL "PALACE" DOORWAY WHICH WAS MODIFIED IN THE RENAISSANCE THEATRE, AS SHOWN IN FIG. 6, TO PROVIDE A MORE EXTENDED "VISTA"

the Palladian theatre at Vicenza takes on double importance as historic evidence: (1) as preserving the Roman playhouse form, including the rigid architectural stage; and (2) as providing for introduced "scenery" (not as yet changeable). The backgrounds of the Roman and Palladian Renaissance stages are shown in fig. 7. There are extant plans which indicate that certain artists of the time, trying to think through to a more practical combination of the classic stage with provision for pictorial backgrounds, saw a means in the widening of the central "palace" doorway to provide acting space within the "vista." Thus Inigo Jones made a plan and an elevation similar to those shown in fig. 8. And the theatre at Sabbioneta (of which the scene unfortunately no longer exists) showed the whole stage as one narrowing vista (1588); *see* fig. 10.

The next step is illustrated in the playhouse that is usually called "the first modern theatre," the Teatro Farnese at Parma (1618 or 1619), diagram of which is shown in fig. 9. Here the entire stage may be said to have been pushed through the central doorway of the old stage wall, the ornamentation of the Roman *skene* remaining only as decoration of what is now the proscenium

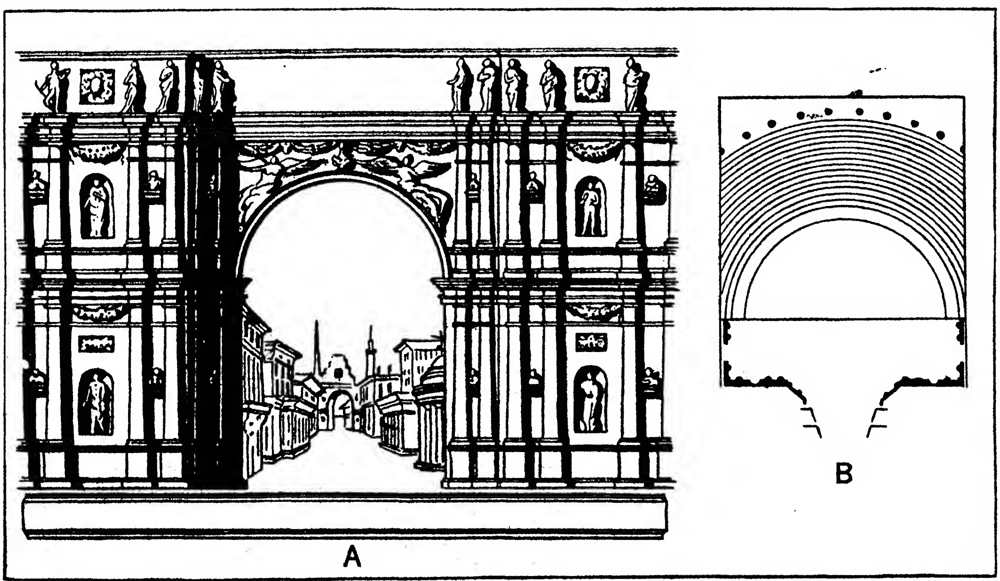

FIG. 8.—PLAN AND ELEVATION BY INIGO JONES OF A WIDENED CENTRAL "VISTA," DESIGNED NOT ONLY TO GIVE A PICTORIAL BACKGROUND BUT TO PROVIDE ACTING SPACE WITHIN THE "VISTA"

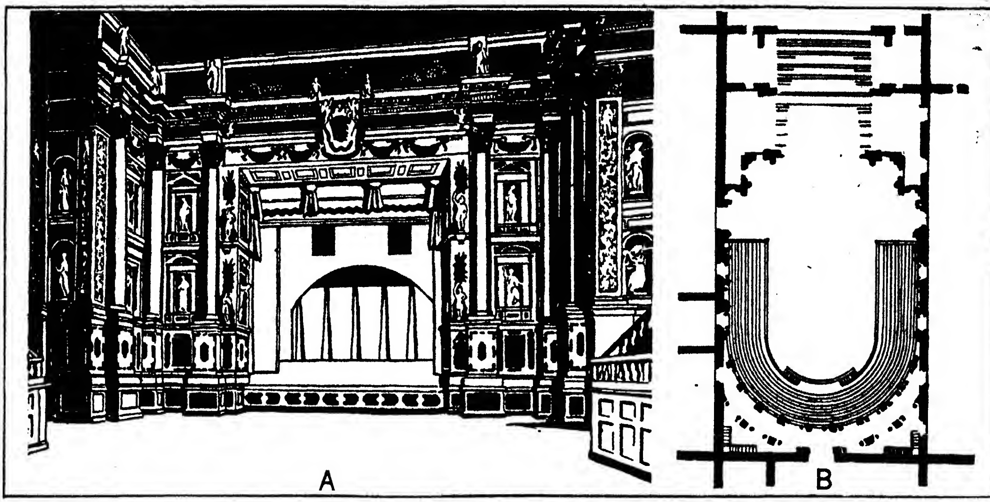

FIG. 9.—PLAN AND ELEVATION OF "THE FIRST MODERN THEATRE" (1618–19), THE TEATRO FARNESE AT PARMA, ITALY. (A) SHOWS THE STAGE CURTAINED OFF FROM THE AUDITORIUM, (B) THE U-SHAPED AUDITORIUM, A NEW INFLUENCE IN THEATRE DESIGNING

arch. The stage within is curtained off from the auditorium (fig. 9*A*) and is thus adapted to changing pictorial settings. From this time on the curtained stage and proscenium arch are unfailing features of the theatre. The plan of the Farnese theatre is particularly interesting, too, as showing the entry of another influence into the shaping of the auditorium: instead of a semicircular bank of seats, as illustrated in the diagrams so far, the auditorium is U-shaped (fig. 9*B*). This influence entered because the masques and court plays had been produced largely in ballrooms or banquet-halls, where one end of the hall had been reconstructed for an auxiliary stage, the main floor left free for dancing, or as an "arena" for pageantry, etc., with the spectators ranged around the three sides away from the stage, perhaps in chairs on temporary platforms, perhaps in balconies. Architects combining this U-shaped auditorium with the curtained proscenium-frame stage soon determined the theatre form that was the basic plan of the famous horseshoe auditorium (fig. 11).

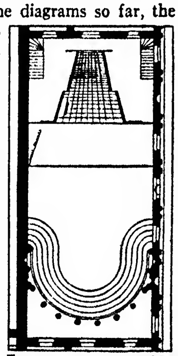

FIG. 10.— PLAN OF NARROWING VISTA. THEATRE (1588) AT SABBIONETA, ITALY, BUILT BY SCOMOZZI

It was this Italian plan that became the standard of theatre building throughout the Western world, conquering successively the French courts, the courts of Austria, Bavaria and other countries to which the Italian Renaissance influence extended, then England (where the Elizabethan theatre form was cast aside —having only the slightest influence after the Restoration), and indirectly America. "Scenery" was soon standardized so that the wings and backdrop restricted the playing space to a wedge-shaped section of the stage floor; and the auditorium lines roughly followed the lines formed by the edges of the wings (fig. 12). This picture scene persisted through two and a half centuries, with ever greater elaboration, demanding larger and larger stages; and the auditorium half of the building kept its many galleried horseshoe plan. With variations toward rounder or narrower auditorium, the general form persisted until late in the 19th century, from smaller court playhouses to immense opera houses.

At first the arena portion of the auditorium was merely a flat floor, and consequently the best seats were not there but at the front of the first balcony; and almost throughout the period of the horseshoe theatre, the main floor sloped but slightly thus allowing three, four or five superimposed balconies or galleries.

Modern Theatre.—The main changes in the construction of the 20th century theatre have been the exclusion of all but one balcony, and the steeper tilting of the main floor, thus throwing the best seats into the orchestra. Even to-day, however, in France and Italy, where the 17th–18th century theatre form stubbornly persists, the orchestra is contracted, and the more expensive seats are in the slightly raised ring of loges and the first balcony above.

During the 19th century there were efforts to reform the "picture" scene, and with it the horseshoe auditorium, which almost invariably had possessed the disadvantage of providing a considerable number of seats, at the gallery ends, which had a poor view of the stage. The first attempts of importance to design a more democratic type of theatre, and one in which "sight-lines" would more logically determine the form occurred in Germany. The Festival theatre at Bayreuth is the most noteworthy example, greatly antedating the present general movement toward the fan-shaped auditorium. Its main outlines are shown in fig. 13.

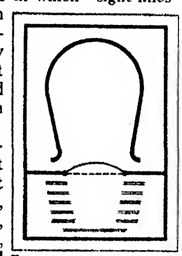

FIG. 11.—PLAN OF A HORSESHOE-SHAPED AUDITORIUM

The impulse was taken up by Max Littmann, the most notable theatre architect of the century-end; his Prince Regent theatre and Künstlertheatre in Munich, and his Schiller theatre in Charlottenburg, Berlin, all with simplified banks of seats, had great influence in both Europe and America. Littmann experimented also with the proscenium frame in an effort to adapt the theatre to the demands of modern stage lighting. More recently architectural practice, particularly in Germany and the United States, has come to the fairly standardized form that is shown in fig. 14. Here the architects restrict the horseshoe bowing-out, since the scene is no longer wedge-shaped but more usually box-like, and the auditorium is narrower in relation to the width of the proscenium opening. (In large cities where ground-value is such an important consideration, the commercial theatres are commonly built with wider proscenium openings and wider auditoriums, but

Nina (centre) has just said, "Make yourselves at home! You are my three men! This is your home with me!" Facial expression and remarks, spoken aside, express the feelings which each seeks to conceal

on the fan principle Standard fire laws impose the necessity for a certain number of aisles and adjacent doorways, and have caused minor differences from the type as it developed in Germany) In general it may be said that the modern auditorium presents a single bank of seats, on a floor uniformly sloping or slightly saucer-shaped, more tilted than during the horseshoe period, and restricted at the sides along lines determined by the edges of the proscenium opening There is usually a single balcony, with a steeply sloped floor, at the rear There are seldom boxes (unless at the back of the orchestra); and modern engineering and steel construction make it possible to dispense with pillars and posts The outline plan is not unlike the plan of the arena or pit portion of the many-galleried opera houses, with the surrounding galleries sliced off. Along with this simplification of plan there has been a general simplification in decoration.

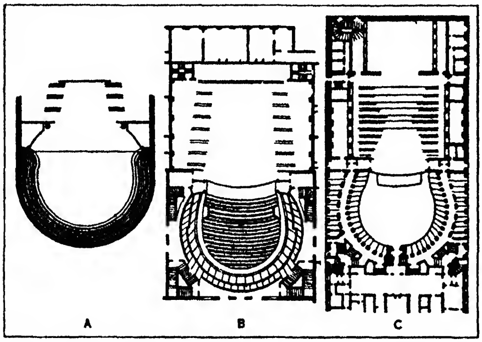

FIG 12 —PLANS SHOWING TYPES OF THEATRE DESIGN USED FROM MIDDLE 17TH TO LATE 19TH CENTURY (A) DRURY LANE, LONDON, (B) THEATRE-FRANÇAIS, PARIS (1790), (C) LA SCALA (1778), MILAN

Two examples of 20th century theatre building may be considered typical of progressive practice (fig. 15). The more radical experimenters have already called for the scrapping of the entire proscenium-frame house, and a return to the principles which determined the theatre form before "picture" scenes were introduced—with reference, however, to modern lighting advances. It may be assumed that some such change will come shortly, and that the return to an architectural stage will demand radical changes in auditorium construction But as yet the several theatres built with formal stages, without proscenium arch, are too different, and their advantages too tentative or too special, to warrant any generalization beyond the proscenium-frame house illustrated above

BIBLIOGRAPHY.—The only historical work in English dealing at all fully with this subject is *The Development of the Theatre*, by Allardyce Nicoll (London and New York, 1927). It is profusely illustrated, particularly as regards the Greek, Roman and English theatres. As a complementary volume, with many illustrations of the Continental court theatres of the 17th–18th century, the reader should consult *Der Moderne Theaterbau*, by Martin Hammitzsch (Berlin, 1906). Another useful reference work in German is Manfred Semper's *Theater*, in the *Handbuch der Archetektur* series (Stuttgart, 1904). In English a useful brief treatment from the 20th century viewpoint is to be found in *Modern Theatres*, by Irving Pichel (New York, 1925). The "standard" work on theatre architecture in English is *Modern Opera Houses and Theatres*, by Edwin O Sachs (London, 1896–98), a monumental work in three volumes, with extraordinarily fine plates; but it can be recommended only with the reservation that the conception of stage art has been so revolutionized in the last quarter-century that it is wholly out-of-date in its viewpoint. For an earlier period one may profitably consult G. M. Dumont's *Parallèle des plus belles salles de spectacle d'Italie et de France* (Paris, 1763). To trace the material about the theatres of individual countries or periods, the reader may best consult the descriptive bibliographies in Professor Nicoll's book

MODERN EXTERIORS AND INTERIORS

The theatre, with its special uses and special restrictions, naturally calls for special architectural treatment. The peculiarly public nature of dramatic art stamped one primary requirement on theatre architecture long before the advertising mania of the present age appeared to reinforce it: it must attract attention and its function must show in outer aspect

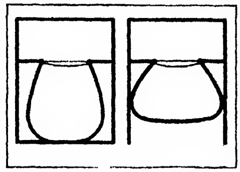

FIG. 14.—TO SHOW STANDARDIZED FORMS OF MODERN THEATRE

The essential architectural beauty of the exterior of a theatre must come not from decoration but rather from the massing of those portions of the walls which reveal the three essential inner parts of the playhouse—the stage, the auditorium and the foyers

Importance of Site.—The art of theatre building has reached its height in Europe where every period developed and perfected its own rich style of architectural expression, and where the conditions of life in the larger cities permitted the theatre to attract attention to itself and its structure through appearance of three or four façades. In Europe a theatre was usually built on a wide street or square—the Paris Opera House (Ch Garnier, arch), the Schauspielhaus in Berlin (Carl Friedrich Schindel, arch.); the Champs Élysées, Paris (A and G. Perret, archs), Staatsoper, Vienna (Vander, Nüll and von Siccardsburg, archs); Dresden Opernhaus (Gottfried and Manfred Semper, archs); or the Prinz Regenten theatre in Munich (Max Littmann, arch)—or even in a park, as in the case of the twin State theatres of Stuttgart (Littmann, arch), and many others Everywhere we find that it is growing more and more difficult to find such ample and predominant sites in the larger cities on account of the high value of land,

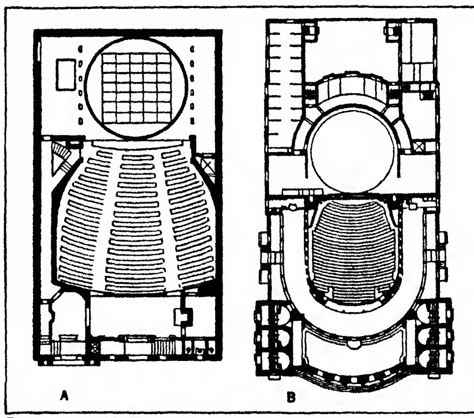

FIG. 15.—EXAMPLES OF FLOOR PLANS FOR MODERN THEATRE BUILDING (A) THE LITTLE THEATRE, NEW YORK. HARRY C. INGALLS AND F. B HOFFMAN. JR , ARCH'TS., (B) VOLKSBÜHNE (PEOPLE'S THEATRE), BERLIN, OSKAR KAUFMAN, ARCH'T

the lengths of blocks, and the type of buildings dominating the view. Difficult conditions reach their acme in New York. The Metropolitan Opera House (Cady, Berg and See, archs.) alone occupies an entire block, and only the Century theatre, opposite Central Park (Carrere and Hastings, archs), can show three sides. The largest theatre in the world, the Roxy, in New York (Walter W. Ahlschlager, arch) is away from the corner and down a side street. In London, among many examples showing one façade only there are the new Carlton theatre (F. Verity, arch), and the Fortune theatre. The theatre architect in all countries has

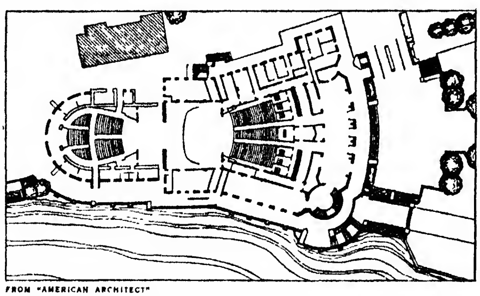
now usually only one façade available to tell the story which two, three or even four told in the past.

Modern Conditions and Restrictions.—The architect limited to one façade facing a narrow street, has found it hardest to show in the outer form of his building the anatomy that lives within. Yet even under these conditions the Guild theatre (C. Howard Crane and Kenneth Frazenheim, archs) manages to mark off handsomely the stage-house like an Italian brick tower above the stucco front of the lower auditorium.

Congestion and fire regulations play particular havoc with theatre architecture, yet several more or less successful attempts have been made to combine necessity with beauty. In the bold Martin Beck theatre (G. Albert Lansburgh, arch) and in the charming Music Box (Crane and Frazenheim, archs.) the inevitable fire-escapes required by law find a pleasant hiding place within porticoes. The Henry Miller theatre (Paul R. Allen and Harry Creighton Ingalls, archs) conceals unsightly alleyways—again required by law—within its Georgian walls The law does not require the builder of a theatre to protect his patrons from the rain while they wait for taxis and motor-cars, yet the marquee becomes inevitably one of the most important items of the façade, unless an arcade or portico has been designed to protect the waiting crowds.

Electric Signs.—The worst problems of the architect who builds theatres in a great city come from the primary requirements of such a building—that it must be seen and tell its story at the greatest possible distance The set-back laws, new treatments of L-shaped, U-shaped, or H-shaped courts in front of tall buildings, and the enormous height of the skyscrapers make period fronts on three or four-storied theatres an insufficient and even ridiculous attraction against the gigantic, varied and vital proportions of the neighbouring buildings To compete for visual notice under these conditions, the theatre owner turns to enormous electric signs, and blankets the façade behind flashing bulbs and painted tin London examples of good exterior lighting arrangements are the Plaza theatre (F. Verity, arch), and the Astoria cinema (E. A. Stone, arch)

The modern architect has to consider as the main requirements in the exterior design of theatres three things which the architect has never before had to deal with These are electric advertising signs, fire escapes and marquees Not until we have made these necessities a part of our architecture, not until these necessary evils have been fused into a thing of beauty and have formed their own architectonic style and expression, can we hope for a new, adequate and handsome theatre façade.



FROM "AMERICAN ARCHITECT"

PLAN OF THE SHAKESPEARE MEMORIAL THEATRE, PRIZE WINNING DESIGN IN THE PROCESS OF CONSTRUCTION IN STRATFORD-ON-AVON, ENGLAND

Type of Entertainment Determines Type of Auditorium.—Each type of dramatic entertainment—including the motion picture—demands its own type of auditorium In the ancient world the Greek theatre developed along lines suited to drama and comedy that employed large choruses, while in Rome something nearer the modern stage came into being as the chorus disappeared. Unfortunately the theatre architect of to-day is much too uncertain of the type of entertainment which will ultimately make use of his creation He may intend the building for popular melodrama, but financial misfortunes may turn it over to motion pictures or to musical revues. It is only in the smaller communities that a theatre should be built for general usage, and some compromise arrived at which will suit both stage and auditorium to almost any kind of entertainment.

The Motion Picture House.—In a motion picture theatre, where the attention of the audience is concentrated on a silver screen and on figures of actors that are well over lifesize, the auditorium may be very deep without incommoding the spectator. On the other hand, it must not be too broad or too high, for that would distort the appearance of these two-dimensional figures on the flat screen The mass of the audience must be concentrated in the centre and placed on two main floors. The theatres that carry this out most notably are the Marmorhaus, Berlin (Hugo Pal, arch), the U-T Theater, Berlin (Fritz Wilms and Max Bischoff, archs.), the Capitol theatre, New York (Thos W. Lamb, arch), the Roxy theatre, New York, the Plaza theatre, London, the Empire theatre, London, the Piccadilly theatre, London.

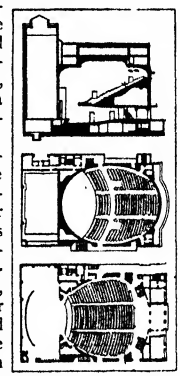
PLAN OF THE EASTMAN THEATRE, ROCHESTER, N Y , DESIGNED BY GORDON AND KAELBER, ARCHITECTS, AND MCKIM, MEAD AND WHITE, ASSOCIATE ARCHITECTS

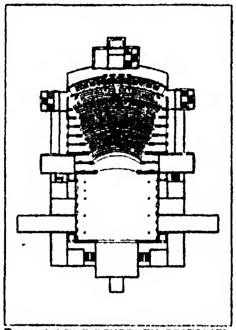
The Revue Theatre.—The theatre intended for the use of the big musical revue is rather closely related to the moving picture house, though it, too, has its peculiar requirements. Here the main interest lies in the stage picture, the beauty of costumes and scenery, and so a large auditorium is possible Care must be taken, however, to avoid too great a depth, for comedy scenes and solo singing demand more intimacy and a closer view of the performer than in the case of the motion picture. Here it is of great importance that the height of the seats in relation to the stage floor shall permit everyone in the house to see the feet of the dancers. For the revue house—as well as for any theatre, that is not used on the one hand, for the motion picture, or on the other for the strictly realistic, peep-show type of drama —the architect must take great care to avoid anything in the proportions of stage and auditorium that may indicate a separation between the actors and the spectators. He must strive to use every means for uniting both groups in close spiritual contact.



LONGITUDINAL SECTION OF THE ZIEGFELD THEATRE (TOP), PLAN OF BALCONY (CENTRE), AND OF THE ORCHESTRA (BOTTOM), DESIGNED BY JOSEPH URBAN AND THOMAS W LAMB, ASSOCIATE ARCHITECTS

The realistic play of the type which presupposes the presence of a fourth-wall between the actor and the audience has set special problems for the modern architect. Hitherto he has solved these as perfectly as possible—and, of course, by the very nature of the case he has not achieved anything exhilarating, notable or truly theatric. In the main he has had to restrict himself to a

small auditorium and if he sought larger capacity, a single balcony hung far out over the orchestra floor. He has done away with boxes as obtrusions between the audience and the picture frame. And this picture frame has become a definite and complete separation between the audience and the actors. In decoration he has been forced to subdue the colour of his auditorium so as to leave the audience in peep-show darkness while the play goes on. Two of Ingalls's playhouses in New York, the Little theatre and the Henry Miller, meet these stultifying conditions as well as they can be met.

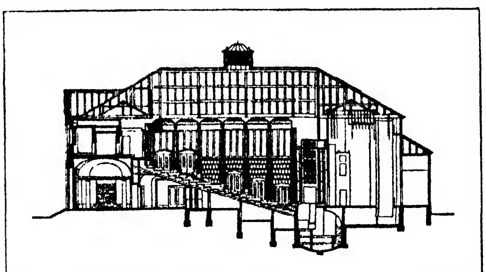


PLAN OF THE BEYREUTH FESTSPIELHAUS. MANFRED SEMPER, ARCH'T: THE FAN WITH STRAIGHT SIDES AND A WIDE SPLAY WAS USED

Problems of Site and Seating Capacity.—Within the limits of the particular piece of land on which he has to build, the architect must work out as large a seating capacity, and as roomy and convenient an arrangement of stage, dressing rooms, and foyers as possible Where the site is rectangular the problem is comparatively simple, but where the site is irregular it is often difficult to accommodate the auditorium and stage

The architect has generally to secure the largest seating capacity possible on a given site. Usually this has meant widening the stage and still further widening the fan-like auditorium until only revues can be properly presented. The architect plans one very large, overhanging balcony because the higher prices that can be charged in a balcony, compared with a second balcony or gallery, more than make up in financial capacity for the greater number of seats that a double-decker arrangement provides

Occasionally the architect tries some new method of getting a large but intimate auditorium on a piece of property of restricted size A popular method is to place the stage in one corner of the site instead of along the back, and then to throw the auditorium diagonally across the lot Though this arrangement is better suited to the almost stageless motion picture theatre, it has been used in a "legitimate" theatre, The Ambassador, New York (Herbert J. Krapp, arch) Among large motion picture houses with



FROM LITTMANN, "DAS MÜNCHENER KÜNSTLER THEATER"

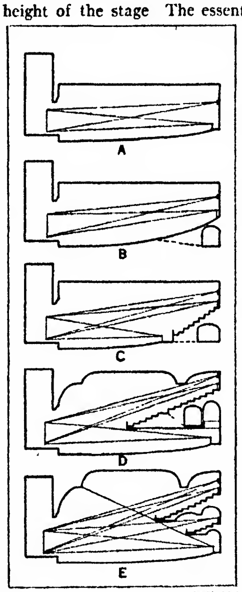
SECTION OF MUNICH ARTISTS' THEATRE, SHOWING THE STEEPLY SLANTING FLOOR

well-equipped stages which have also utilized this seating plan are the Paramount theatre, Palm Beach, Fla. (Joseph Urban, arch), the Bondi theatre, Sydney, N S W. (C Bohringer, arch.), "the Majestic," Leeds (Messrs. Skinlet and Maxwell, archs) and the Roxy, New York.

Auditorium Shapes.—The shape of the auditorium itself, which used to be invariably a horseshoe, is now most apt to take the form of a fan with convex sides curved in towards the front and rear. An elliptical form has been tried with good decorative effect in the theatre of the Carnegie Institute of Technology, Pittsburgh, Pa. (Alden and Harlow, archs.) and in the Ziegfeld theatre, New York (Urban and Lamb, archs.). The New Cinema, Portsmouth (A. E. Lutte, arch.) is also a good example of this type. The fan with straight sides and a wide splay was used in the Beyreuth Festspielhaus (Manfred Semper, Arch) where the boxes are located in a straight row across the back of the theatre and the "diamond horseshoe" of boxes eliminated.

Acoustics.—Any divergence in shape from auditoriums tried and tested by time involves the risk, of course, of producing bad acoustics But the danger is far from absent in any theatre for the problem of acoustics is the most difficult that an architect has to meet. In 1895 Prof Wallace C Sabine of Harvard, beginning by means of formulae and of photographs of sound waves in models of auditoriums, was able to determine in advance with a certain degree of accuracy the acoustic properties of a given design of theatre. Later research has devised methods of correcting bad acoustics by means of felts, wires, sounding boards, etc, but the fact remains that the best material for the interior of an auditorium, wood, generally cannot be used on account of the restrictions of the fire laws

Visibility.—A problem of theatre construction which has not had as complete a study and formulation as it deserves is the line of slant in auditorium floor and balconies in relation to the height of the stage The essential aimed at is the most perfect visibility from every seat in the house One of Germany's theatre reformers, Littmann, in a desire to give the last row as clear a view as the first, prescribed a very steeply slanting floor, but made the grave mistake of making it merely a straight inclined plane The result was that the front rows had more range of vision than they needed, while the last rows suffered from the feeling of looking down a narrow tunnel The better method, which is generally followed today, is to begin with little or no inclination at the front, and then to increase this radically towards the rear The slant of the auditorium and, of course, of the balconies, too, is controlled in most cities by the requirements of the building regulations The height of the stage above the auditorium floor is not so restricted, and can be worked out freely to give the whole auditorium a complete and comfortable view of the actors upon the stage It is often very badly handled



FROM SEXTON AND BETTS, "AMERICAN THEATRES OF TO DAY" (ARCHITECTURAL BOOK PUBLISHING CO.)

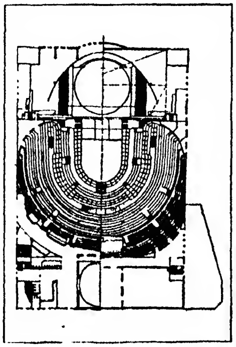
LONGITUDINAL SECTIONS OF VARIOUS TYPES OF THEATRES

A One floor type, B. Bleacher type, C. Stadium type, D. Single balcony type, E. Balcony-mezzanine type

The slant of the floor and the arrangement of the balconies bring out many interesting possibilities. Krapp combined the "bleacher," "stadium," and "single balcony" types in a so-called "arena" arrangement used experimentally in Chanin's Forty-Sixth Street theatre, New York, and better worked out in another Chanin playhouse, the Majestic, New York. The purpose is to get a very deep orchestra floor by running the entrance foyers under its steeply slanting rear. The Guild theatre, New York, (on a suggestion by Norman-Bel Geddes) managed to place its roomy lobbies under the auditorium without raising the latter so far above the street as to bring it into conflict with the fire regulations.

German Seating Arrangements.—In most countries fire laws have prevented the wider use of an arrangement of the

seats themselves which has found general popularity in Germany. This arrangement abolishes the aisles dividing the floor into sections, and the seating of the audience in one unbroken mass of solid, continuous rows from wall to wall. Adequate entrance and exit are obtained by spacing the rows a little wider apart than in the ordinary arrangement, and making the walls of both sides of the auditorium a succession of doors emptying into the lobbies. The effect of this arrangement is that the spectators are seated in one solid mass An equally important consideration — which should argue a change in fire regulations—is that a house seated on the German model can be cleared in half the time it takes an audience to press into and up the ordinary narrow aisles. This German seating arrangement has been used with success in the Kenneth Sawyer Goodman Memorial theatre, Chicago (Howard Shaw, arch), which happens to be located outside the jurisdiction of the Chicago fire commissioners



FROM ZUCKER 'THEATER & LICHTSPIELHAUSER (WASMUTH)

FLOOR PLAN OF SECOND AND THIRD BALCONY OF THE GROSSES SCHAUSPIELHAUS, BERLIN, DESIGNED BY HANS POELZIG, ARCHITECT

Stage Lighting from the Auditorium.—The stage arrangements, except as to adequate dressing rooms, property rooms, and scene stacking space, are matters for the theatre technician—scene designer, electrician, etc —not the theatre architect, although the architect should see that there is ample space allowed. Something should be said, however, on one point connected with lighting arrangements; this is the necessity of providing room in the auditorium for the placing of lights for the illumination of the stage and the actors In 1914 Granville Barker introduced at Wallack's theatre in New York a row of powerful incandescent lamps around the balcony rail to replace the footlights David Belasco took the next step forward by installing such lights in a recess in the balcony rail closed by doors automatically controlled from the stage switchboard Some such provision, or perhaps a light bridge concealed in the ceiling beams, as in the Yale university theatre, New Haven, Conn. (C H Blackall, arch), or the Guild theatre, New York, ought to be a part of every architect's plan of a new house

Decoration.—The decorative problem within the auditorium has found many solutions, depending on the kind of dramatic entertainment to be presented The modern decorative movement towards larger, smoother and less ornamented surfaces has its peculiar applicability to the playhouse, where the eye should not be distracted from the players by too ornate detail. Yet there is something undeniably exciting and truly theatrical in the rococo interior of the Residenz theatre in Munich (Cuvilliés, arch.), and Oskar H. Kaufmann, beginning with a rigid simplicity in the Volksbuehne and other houses in Berlin, has had delightfully amusing recourse to the Chinese baroque for the Theater am Kurfuerstendamm and the Komoedie also in Berlin. The limitations and the values of decoration depend, after all, on the interpretive genius of the architect

The new attempts to break away alike from the old horseshoe opera house and the realistic peep-show theatre all look back for their justification to the history of the development of playhouse architecture, and borrow heavily from the past.

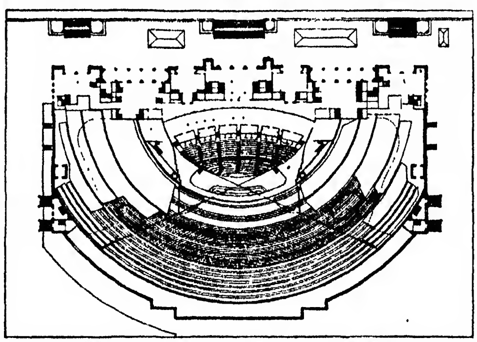
Development of the Opera House.—Following the Fall of Rome and the decline of classic culture the classic theatre disappeared save for a renewal of some of its form and spirit during a few brief decades of the Renaissance The theatre, and especially the early opera, supposed ironically enough to be founded on classical tragedy, became a mere excuse for brilliant court festivity. As a result of the desire on the part of the audience to be observed by one another good visibility for the stage suffered The style of the popular Italian opera predominated. The singers delivered their important arias as close to the prompter's box as possible while the chorus stood practically inanimate. Contact between the stage and auditorium disappeared and with it the spiritual union of performers and audience. Good acoustics and a brilliant social display were the demands made upon the Baroque theatre. The decorative type of auditorium with its heritage of the richness of the Renaissance and the charm of the rococo had originally been a thing of gorgeous, festive yet graceful beauty

In the course of years it added to the pernicious Italian shape new horrors of decoration and became that horrid overladen gold-and-plush spectre of its former self of which unfortunately we still see examples.

Toward the latter part of the nineteenth century, however, came evidence of change and reform Splendid acting was increasingly in demand and rich settings and appropriate historical costumes were considered essential to enhance the beauty of operatic music The problem of displaying these adjuncts began to make even the architects of the opera houses see that their art had reached a standstill and that some attempt had to be made to recapture the spirit and some of the form of the classic stage. Their efforts were partly compromises in the shape of the auditorium, partly a simplification of the baroque theatre following the more serious and less social tendencies of the legitimate theatre

The reform dates from the work of the Sempers in mid-Victorian days and is punctuated with March's Festbuhne for Worms in 1887. The attempts at a new type of auditorium seldom aim at a direct return to the classic but only to one of its descendants, the Shakespearian stage Already the results in projects and even a few completed playhouses have been notable

The Circus Theatre.—Steele MacKaye, actor, playwright, artist, director and inventor, was the first to produce a notable plan for a circus-theatre. In 1892 he had almost completed in Chicago as part of the World's Fair a remarkable structure called the Spectatorium Like so many efforts at the "theatre of the 10,000," it strove to gather together the huge audiences of Greek days and to bring them into close contact with all the possibilities of the stage. MacKaye devised a means of bringing his actors and choruses up from under the audience through steps in the orchestra pit He invented a proscenium opening that could be



PLAN OF STEELE MACKAYE'S SPECTATORIUM-THEATRE DESIGNED TO SEAT TEN THOUSAND PEOPLE AND TO INTRODUCE SLIDING STAGES, A LINOLEUM CYCLORAMA AND MANY OTHER MODERN STAGE REFORMS

made wide or narrow, thin or deep He provided a crescent-shaped stage with scenery sliding on tracks. This stage could be flooded with water. He closed in the back of his semi-circular stage with a linoleum cyclorama. He invented cloud machines for projecting moving clouds on the sky. There were few reforms of modern stage technique that this remarkable man did not foreshadow in this project, which the American financial panic of 1893 arrested when only half built.

It was along the lines of this MacKaye theatre that Max Reinhardt built when he developed his performances of Greek tragedies

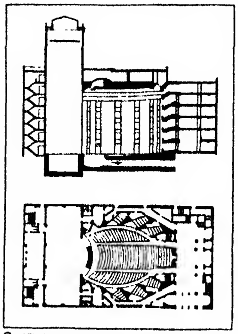
CELEBRATED FIGURES OF THE CHINESE STAGE

1. Ch'êng Yen-Ch'iu, the greatest contemporary singer of popular female rôles, appearing as a female warrior
2. Yang Hsiao-Lou, left, and Wang Fêng-Ch'ing in "Lien Hua Hu," (Lotus Flower Lake). Yang Hsiao-Lou is reputed to be the greatest contemporary singer and actor of male K'un Ch'ü (classical) rôles
3. Han Shih Ch'ang, the greatest contemporary singer and actor of female classical rôles
4. Huo Shou-Chên as "Ts'ao Ts'ao," the traditional villain of the Three Kingdoms in "Ch'ang Fan P'o" (Long Hillside)
5. Chen Pi-Yen, right, and Chin Chung-Jên in "Hung I Kuan" (The Rainbow Pass)
6. Mei Lan-Fang in "Tai Chên Wai Chuan" (The Story of Yang Kuei-Fei)

in circus buildings into the finally realized Grosses Schauspielhaus in Berlin (Hans Poelzig, arch.) Here he came close to the true conditions of the classic stage, with the actors appearing on a semi-circular orchestra floor almost in the midst of the spectators, and then retreating up steps to a completely equipped stage with sky-dome, revolving stage, and all the modern appurtenances The son of Steele MacKaye, Percy MacKaye, realized many of the values his father had planned in his open air performances of "masques" at St Louis, New York and Cambridge, Mass., between 1912 and 1927.



SECTION AND PLAN OF THE REINHARDT THEATRE, NEW YORK CITY, DESIGNED BY JOSEPH URBAN, ARCHITECT

Copeau's Theatre.—At the opposite extreme in size, Jacques Copeau created in the Théâtre du Vieux Colombier, Paris, a playhouse which united the actors on a naked architectural stage with an audience seated within auditorium walls that continued back unbroken by any proscenium to make the walls of the stage itself The Théâtre du Marais, Brussels (Louis Jouvet, arch), and other projects were offshoots from this pattern.

Non-realistic Theatres.—The stimulus of trying to give Shakespeare's plays as he wrote them and not garbled and condensed to fit the modern realistic theatre has resulted in a number of attempts to revive the conditions of the Shakespearean stage on the stage of an ordinary theatre This has brought back canvas make-believe, the portals of proscenium doors which all English theatres rejoiced in a century ago From merely represented as part of the scenery, these means of linking the actor and the auditorium have now been built into the actual prosceniums of many new houses, especially in the "little theatres" built here and there about the United States Some such theatricalizing of the stage is present in the Werkbund Theater, Cologne (Van de Velde, arch), with its tripartite division of the

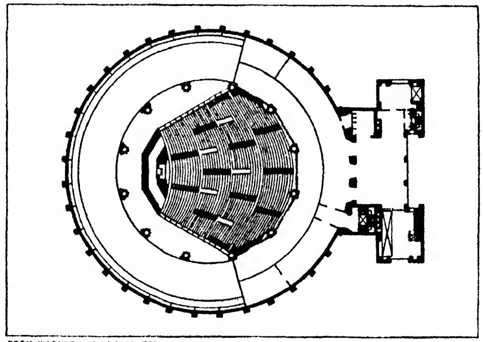
SECTION OF A THEATRE DESIGNED BY OSKAR STRNAD, VIENNA

stage, and in A. and G. Perret's and A Granet's theatre in the Arts Décoratives exhibition in Paris. But certainly the handsomest playhouse of a formal and ultra-theatrical sort is the Theater in der Redoutensaal, Vienna (Sebastien Heinrich, arch.), a stage with permanent walls but no proscenium or fly gallery, set down in a ballroom of Maria Theresa. From productions in this house Reinhardt turned to the rejuvenation of a lovely old Viennese theatre, the Josephstaedter, and then created in Salzburg in the Reitschule a non-realistic playhouse which he hopes finally to replace by a magnificent, neo-classic festival theatre from the plans of Poelzig

Radical Projects.—Radical designs, which are as yet largely projects, include those of the distinguished American pioneer architect, Frank Lloyd Wright Norman-Bel Geddes has devised a remarkable theatre with the stage in one corner, the whole auditorium and playing floor surrounded by a single dome of light. He has also devised a long rectangular playhouse with the action



FROM WASMUTH, "MONATSHEFTE FUR BAUKUNST"

PROJECT OF A CIRCULATORY STAGE IN A THEATRE, DESIGNED BY OSKAR STRNAD, VIENNA

passing on a stage stretching down the middle from end to end, and with the audience on both sides, as well as a circular playhouse with the stage in the centre, a scheme suggested by Robert Edmond Jones's project for Shelley's *The Cenci* in a prize ring Variants on the usual relations of stage and audience are many, including a scheme by Friederich Kiesler for two opposing auditoriums sharing the same stage One of the most remarkable is Oskar Strnad's circular theatre with the audience seated in the centre and the big ring of the revolving stage coming into view a segment at a time

Out of all these attempts and projects, a really healthful new theatre is slowly but surely developing It will not reach its full maturity until actors can enter naturally and easily from the auditorium as well as from the stage and step down from their own level to the level of the spectators When every division between the world of the actors and the world of the spectators is eliminated, and when those who give and those who receive are —in the spirit of the classic theatre—once more surrounded by the walls of the same room, then and only then will it be possible to meet completely all the demands not alone for proper acoustics and proper visibility, but for purely spiritual pleasure achieved without hampering physical effort

GENERAL PLANNING

Real development in modern theatre architecture started in the latter part of the 19th century and each year has brought added progress in planning and designing. Theatres 10 years old are out of date, while some 20 years old are practically obsolete From the point of view of construction, new methods due to the advent of modern steel framing, progress made in the science of lighting (*see* Stage Design) and the necessary adherence to present day building codes have been a few of the potent factors in this advancement Changing social and economic conditions continue to affect the theatre and its planning radically. The old style theatre with posts and horse-shoe balconies is gone. The theatres of only a few years ago containing a balcony and gallery

are now "old fashioned."

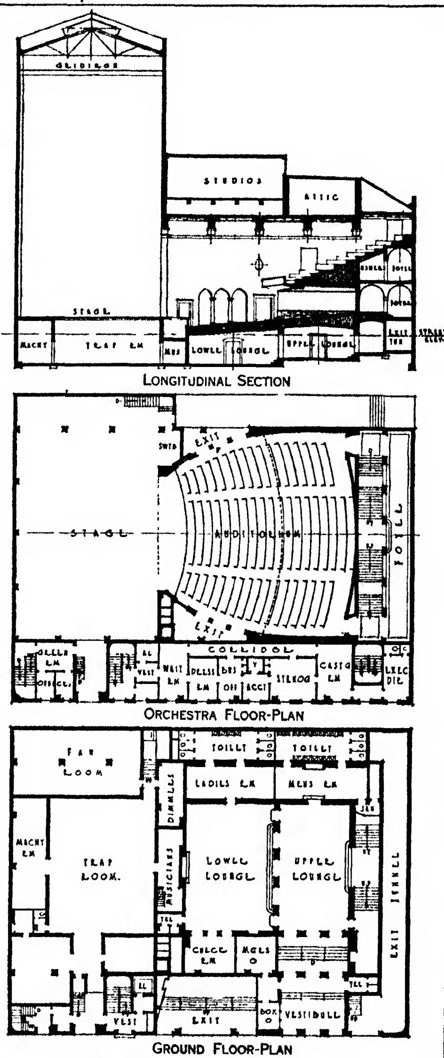
The modern theatre consists of a lower floor, or orchestra level, and one large sloping balcony. Sometimes a small mezzanine or loggia is placed between the lower floor and balcony. Every seat must be so situated as to have an unobstructed view of the stage. The auditorium floor and balconies must have the proper curve or incline, to ensure proper "sight lines." The acoustic problem must be worked out so that each patron will hear distinctly, to accomplish which methods that eliminate as much as possible all reverberations must be employed. The stairways, foyers, lobbies, box offices, lounges and retiring rooms should be so laid out as to avoid confusion. The architect should strive for perfect circulation of the patrons. The box office should be situated at the right hand side on entering a theatre. The entrance doors and the main stairs to the balcony should also be placed at the right hand side. The exit doors and a stairway from the balcony to be used when leaving the theatre should be on the left hand side of the main lobby. This arrangement allows the incoming and outgoing audiences to pass without mixing.

On account of the high land value, it has often been necessary for the architect to get a maximum building on comparatively small property, with the result that after space has been utilized for an adequate stage and maximum seating capacity, there remains in most cases comparatively small areas for public spaces such as foyers and general lounges. The traffic problem in most of the larger cities makes it impossible for the entire audience to be in their seats at the rise of the curtain. Late arrivals coming into the small vestibule and foyer spaces of the usual dramatic theatre spoil the opening of many performances. A constructive development to alleviate this condition is represented by the device used in the new Theatre Guild theatre in New York, where the audience enters the theatre by a lower level than the street. On this level are situated the lounges and retiring rooms. A large stairway leads to the promenade and the rear of the auditorium from which the patron enters without confusion. Although in this scheme the main floor is above the street level, the necessary slope of the floor brings the lower part of the main auditorium to street level elevation, where the main exits are situated.

The motion picture industry has had more to do with the building and development of theatres than any other agency. The so-called "movie" is usually a theatre with a fairly large seating capacity, spacious provisions for orchestra and organ, but no stage. A small platform usually suffices for the performance given in addition to the pictures. These auditoriums in most cases are treated architecturally and decoratively as one room. As this type of theatre is usually longer than it is wide, the auditorium treatment is as elaborate in the rear as at the front, giving the patron sitting in the rear seat the feeling of closeness to the stage.

Problems.—Architecturally, each type of theatre has distinct problems. Dramatic houses and opera houses have to care for audiences during intermissions, these audiences usually leave en masse; therefore, lounges, foyers and promenade spaces must be provided to allow the free movement of the people and to avoid congestion. Most moving picture theatres are run continuously and the patrons for the most part come and go at no specific time, in them perfect circulation is most necessary. The exterior treatment of all types should be somewhat festive and characteristic of their function. More restraint and dignity should be expressed on the exterior of dramatic than vaudeville or picture houses. Since the moving picture theatre depends a great deal on the passer-by for its patrons, its exterior should be designed to attract attention and should have a very inviting and unusual façade; electric illumination is utilized to a great extent to enliven and add glamour to it.

Every theatre should have a marquee at the entrance. This marquee or ornamental canopy is used for a double purpose: (1) to protect the public on entering or leaving the theatre during inclement weather; (2) to afford an excellent means of advertising. The marquee of a modern theatre is in reality a very ornamental electrical sign attached to the three sides. It should be carefully designed so as to add to the appearance of the façade.

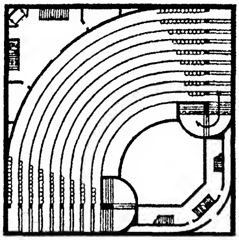


PLAN OF THE THEATRE GUILD THEATRE, NEW YORK CITY, DESIGNED BY C. HOWARD CRANE, FRANZHEIM AND BETTIS, ARCHITECTS

Rarely does one of these signs enhance the architecture of the building and in most cases hideous results are obtained because it is designed by inexperienced draughtsmen without regard for the architectural treatment of the exterior. However, much more extensive consideration is now being devoted to the problem of the marquee not only by architects but by sign makers also. In consequence of this changed attitude more harmonious and artistic results are being attained.

The old method of treating the interior of theatres was first to design an elaborate proscenium arch or frame, then to treat the proscenium boxes very ornamentally but less elaborately than the proscenium. From these boxes back to a point near the centre of the balcony, a very simple treatment was generally used, and

from this point to the extreme rear a very plain one. In this type the audience was really sitting in so many different rooms, varying with the distance from the stage. There was no continuity of design. The modern method is to unify the auditorium or to treat the theatre as one room, making no distinction in elaborateness of detail because of location. Psychologically, a higher 'audience *moral* is effected as this scheme of decoration, eliminating segregation by sections, establishes a feeling of equality between patrons



NORMAN BEL GEDDES THEATRE
This theatre provides for a stage and auditorium both under one domed roof. The triangular stage in the lower right corner sinks into the basement for changes of setting

Increase in Size.—The latest development in the design of the theatre is brought about by the building of the present-day "super cinema palace" Here the architect has been allowed to use to the fullest his imagination and ability. The acoustics and sight lines must be perfect Unusual lighting effects must be devised and provisions made for the latest modern development such as talking pictures, public address or amplifying systems, and mechanically operated stage and organ lifts. These theatres operate usually on a 12-hour schedule and are often attended by as many as 30,000 persons in one day Expert planning is necessary adequately to house and control these large audiences Some noteworthy examples have been completed recently; they are rich in ornament and gorgeous in colouring and lighting effects, and they are usually extremely elaborate in furnishings Due to their extreme widths and to the essential absence of posts, these large modern theatres present great structural problems. Fresh, cooled air in summer and pure, warmed air in winter must be constantly and evenly distributed to every part.

Equipment.—Theatres seating between 5,000–6,000 persons, with large comfortable chairs liberally spaced, are now being built in nearly all the large cities of almost every country Theatres of this size would ordinarily produce serious problems in acoustics. By means of public address systems or a series of cleverly concealed amplifiers, evenly distributed over the theatre, an operator, by simply turning dials similar to those on a radio set, can increase or diminish the stage performer's voice at will Proper precautions must be taken to overcome reverberations. This is usually done by careful and scientific use of absorbent materials, of either specially prepared plaster or felt. Disappearing organ and orchestra lifts, enabling large orchestras to enter and leave the pit without confusion to the audience, are necessary. They also permit the orchestra to be raised in full view for the overtures and special numbers, and to be concealed when playing incidental music accompanying the pictures These lifts or elevating platforms are controlled by push buttons fixed by the leader's desk. The operating rooms or projection booths are becoming the most important part of the entire ensemble. With the introduction of talking pictures, coloured photography and amplifying systems, projection booths have to be very carefully planned They are strictly fire-proof and contain all the modern fire prevention equipment possible. Automatic shutters cover all openings Metal furniture is used throughout, and a decorative note is often afforded by fine tiles. Dressing and rest rooms, including showers and toilets, are provided for the operators, and there is usually a separate room for rewinding film.

The stage equipment is also of the latest and finest description The switchboard, controlling the many coloured effects both on the stage and in the main auditorium, is a complicated work. With its many-coloured pilot lights, pre-set switch handles, and numerous other controls it almost resembles a complete organ manual and is almost as difficult to operate. The old-fashioned fly gallery and pin rail, with sand bags for counterweights, is gone. The modern method of handling scenery is by the latest improved counterweight systems The operation of a small lever will bring a drop into position quickly and without effort. The controls are usually placed on the stage level. Wire cables have replaced the old-style ropes, and gas pipes the wooden battens, to which the scenery was formerly attached. All stages are equipped with sprinkler systems, automatic ventilators and fire curtains Modern safety laws require fire-proof scenery, with the result that the fire hazard, in the present-day theatre, is reduced to a minimum One of the most important pieces of stage equipment to-day is the cyclorama. This is a large elliptical-shaped piece of scenery reaching from the stage floor nearly to the gridiron. It is absolutely plain and usually painted a neutral tone so that all kinds of lighting will be effective on it It is used as the sky or back piece of the settings. The cyclorama is unequalled as an agency in obtaining beautiful stage effects The usual cyclorama is constructed of plaster or heavy sheet boarding and in many instances also acts as a sounding board.

The following represents a list of some of the rooms required in the operation of a large modern theatre. assembly room or green room; dressing rooms; chorus and ballet rooms, for both men and women, all equipped in a modern manner with bath and toilet facilities; stage manager's and assistant stage manager's office; wardrobe rooms; commissary department; carpenter and electrical shops; large and small property rooms; private offices for the conductor, assistant conductor and organist, a music library and a fire-proof vault for sheet music storage; a lounge room with necessary toilets and locker rooms adjoining, for the musicians, an instrument storage room; soundproof motor rooms for the organ blowers and mechanical lifts; rehearsal room with picture screen and operating booth; locker and toilet rooms for the men and women ushers; building superintendent's office, lockers and wash rooms for the scrub women; numerous small rooms for electric lamp storage and other supplies One of the greatest developments is in the lounges and retiring rooms provided for patrons

MODERN THEORY OF DESIGN

To the Greeks, the theatre was their most vital creative expression, and they succeeded in achieving results that for "pure theatre" have never been surpassed They built them to look like theatres and to dignify what transpired within them The Greeks lived in an age of imagination. Their knowledge of the material world was much more restricted than ours It was as uncharted to them as the universe is to us, and life had a greater interest for them because of this mystery In this mood, they created their drama. Their tragedy penetrated the mysteries of nature beyond the humdrum of ordinary life Their comedy was carried to an extreme that, to our gradually neutralizing mind, appears exaggerated and vulgar Civilization has by degrees impoverished its audiences from an enthusiastic appreciation of extremes toward a glorification of the commonplace mean

We live in an industrial age. We should have theatres that belong to our time, drama that voices this time. Instead, our theatre is a secondary expression We exercise our emotions by reading daily papers, riding in automobiles, listening in on the radio, playing bridge and seeing mediocre motion pictures. The theatre is in a state of sham. The plays, the actors, the scenery, all try to make audiences forget they are in a theatre The buildings themselves are made to look like office buildings, taverns,

museums, Renaissance palaces, Spanish missions or casinos To plan a practical theatre, the designer, architect, or engineer should possess a knowledge of theatres, past and present, and of the latest experiments toward the future, with an experience in the theatre that would class him with such specialists as are called upon to build our sky-scrapers, suspension bridges and subway tubes In exterior design, the most conspicuous elements, such obviously dominating features as the electric signs, the *porte cochère,* the huge cubical mass of the flying space above the stage, offer problems of unusual contrast specifically in theatre design

Primarily, the theatre in this modern world, from every standpoint, lacks style. Inside and out, it should be distinguished It should look and be "theatre," in its architecture, plays, acting or staging Theatres naturally vary in size, requirements and class of entertainment. The point of view of the artists engaged in the theatre should likewise vary The working parts of a theatre must possess the utmost flexibility, must be alterable, in simple practical terms, from one person's use of it to another's, hampering experiment as little as possible Until the theatre, architecturally, becomes more flexible, the dramatist, producer, designer, will continue to have difficulties in exploring new forms For any radical or improved or experimental idea, in dramatization or staging, beyond what has been developed in the last 15 years, the present stage is inadequate It suffices for only a few types of plays, and is completely impractical for any style out of this groove It is probably the most restricting theatre man has ever conceived New basic ideas of architecture will materially stir the imagination of everyone connected with it Instigate a type of stage of a three dimensional order and see what happens in the actual creative work in the theatre

To any student of the subject, the development of the theatre since the Greeks shows gradual deterioration The single item that has most influenced these changes is the proscenium arch There was no arch in the Greek theatre, but by successive stages from that time to the present, the arch idea has developed Its two dimensional aspect imposes an effect which is deadening, as compared with the exhilaration of an audience surrounding the actors, such as we get in the circus There is no more reason or logic in asking an audience to look at a play through a proscenium arch than there would be in asking them to watch a prize fight through one At a prize fight, although each individual looks into the ring from one point of view, a more intensified atmosphere is gained by the sight of the audience seated on all sides of the ring In an art gallery, looking at a piece of sculpture, you instinctively walk slowly around the object to view it from different directions, rather than merely standing and looking at it as you would a painting. The exaggerated importance of the picture-frame stage of the past generation is undoubtedly due to lack of imagination of the minds working in the theatre After all, the proscenium in its present maximum form has only existed over one-fifteenth of the time that has lapsed since the theatre of Dionysus.

In thinking of the theatre, we naturally begin with the stage. The auditorium is built around the stage and a relationship must be maintained between these two major elements. In nearly all modern examples, the stages are too small in proportion to the auditoriums Half of the audience is in a poor position to see and hear The inadequacy of the stage is accepted as a matter of course, since the actors have sufficient space to move in during a performance Actually, the part of the stage that the actor utilizes during the playing of a scene is only about a tenth of the total cube required for stage purposes The off stage space (to both sides and rear of the acting area) should equal three times the floor space of the acting area in order to handle adequately the changes of settings In most modern theatres, it is not even equal to it The entrances and exits for actors, the facilities for handling scenery, properties and electrical apparatus are neglected correspondingly The flying space (above the stage) should be four times the height of the maximum scene, but seldom is. The present-day stage does nothing for the dramatist but cause him to worry as to how this or that idea will be visualized in two dimensional terms, and it has gradually reduced the actor to an immobile loud speaker. The last few years have brought out various mechanical features, such as the application of the hydraulic, revolving, sliding and turning-over principles for changing part or all of the stage with its scenery; and a permanent plaster cyclorama to replace the drop cloth painted to represent a sky, upon which light of any colour can be thrown. But although all of these are important, they fail to get at the root of the difficulty, which is the adjustment of the style and proportions of the theatre to its uses and needs while the building is being planned.

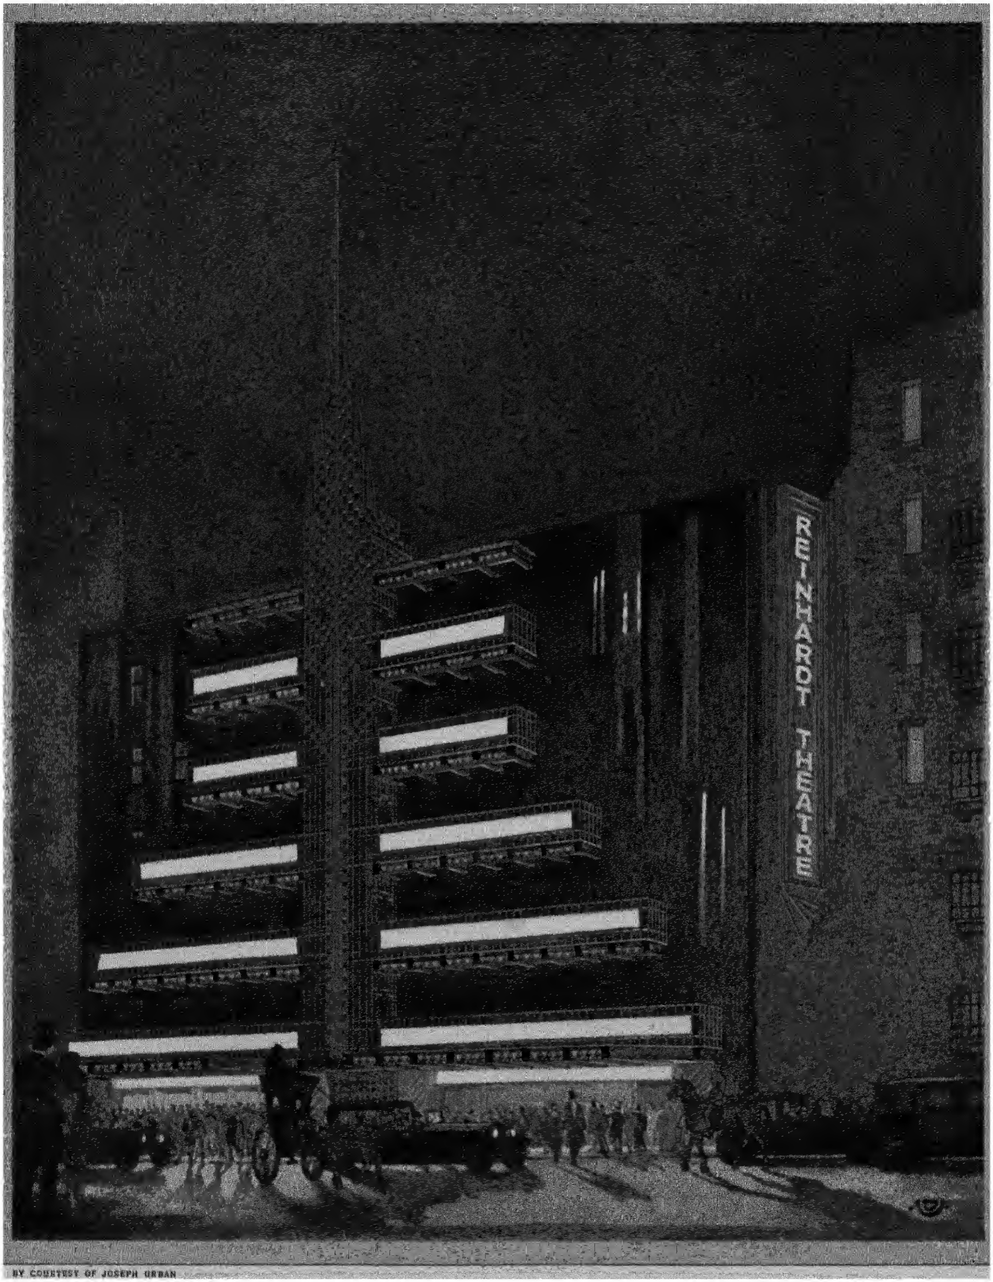
The auditorium should be designed so that everyone may enter easily, reach his seat without annoying other people, sit comfortably, see and hear everything on the stage. The best angle of vision between the stage and the seats, because we are most accustomed to it in everyday life, is shoulder height, yet in our theatres to-day, the best seats, judging from the scale of prices, place the spectator's eye on a level with the actors' feet Each successive row of seats should be at an angle in relation to the stage, so that the spectator does not have to peer between the heads of those in front of him

The audience is the governing factor of drama There can be no drama without it All the dramatist, director, designer and actor do is to project elements which will create a certain effect in the audience's imagination A dramatic production has no significance until it is performed in conjunction with its audience This is why each type of play sifts out its particular audience The theatre takes its place among the arts when the audience not merely witnesses a reproduction of life as it is outside the theatre, but takes part in an experience that does not exist anywhere outside the theatre

Suffering from the limitation that it is not a single-vision medium as that of painters, sculptors, poets, musicians and architects, the usage of the theatre is contradictory to what is accepted as the ordinary working procedure of an artist The dramatist works in a composite medium, which is stage, actor and audience The designer takes the play and develops it for production in all its visual phases, working out its rhythm, movement, manner of staging, setting, costuming, lighting Finally the director, whose position is synonymous to that of the orchestra conductor but who uses actors instead of musicians, rehearses all of these elements into an unified performance The dramatist reaches his audience indirectly through the director, designer and actors His work may be limited by these people, or his stimulation may inspire them to develop his ideas further than he could have done alone The result, good or bad, is the very element that gives the theatre its unique qualities, its advantages and disadvantages, over other forms of expression

The end we seem to be going toward has a more plastic three dimensional stage structure, formal, dignified and neutral, as a basis, its various acting platforms inviting a variety of movement, and provided with adequate space for lighting instead of the cramped condition of the present. Such a structure is designed for the playing of a sequence of scenes of diverse mood, locale and character, not imitative in geographical terms, but creative in dramatic terms, with emphasis on the intensity of dramatic action and its projection to an audience. It will give the impression of being solid and enduring, and will be composed of a variety of levels, ramps, platforms, aprons projecting into the audience, high stages towering to the rear, the whole achieving pictorial qualities by the composition of actors on various levels and their movements in conjunction with lighting. Portions of these settings may or may not be changed to vary as a play goes on Any adequate technique for staging plays should permit of a play being run off in any combination or series of rhythms and not destroyed by such crude makeshifts as darkening the stage or lowering of the curtain to make changes in the setting

Theatres for motion pictures are bound to alter and become distinct from theatres for plastic drama, and in the same way that screen drama is of necessity going to emphasize two dimensional vision, the stage drama, as it develops away from the picture medium in a mental sense, will likewise grow away from it in a physical sense and become decidedly more three dimensional. (N B. G.)



BY COURTESY OF JOSEPH URBAN

THE PROJECTED REINHARDT THEATRE IN NEW YORK CITY

The projected Reinhardt theatre, designed by Joseph Urban as the American home of the well-known German impresario, is an example of the adaptation of theatre architecture to modern needs. On a façade of black glass, balconies of gold metal-work conceal fire-escapes and serve, at the same time, as display boards for illuminated advertisements. The grilled tower contains an emergency staircase

PRODUCTION AND DIRECTION

MODERN TENDENCIES

At one time or another the theatre has used some part of every method of production that we so fervently hail—or condemn—as the last word in modernism to-day, for in 25 centuries it has been all things to all men. It has been religious and blasphemous. It has been as noble as its god-heroes and as petty as its bourgeoisie—whether of Rome or London It has been fantastic and formal in the temples of the living masks where men meet the gods throughout the East It has been minutely realistic Back in Greece, when someone painted wave-lines on the *periaktoi,* and thus let the audience know that it stood by the shore of the sea, the theatre was expressionistic A performance of *The Tempest* on Shakespeare's open stage, with the sailors swarming up the ropes into the canopy overhead, would have satisfied the constructivism of Meyerhold. And when Reinhardt puts *Oedipus Rex* into a circus or gives Calderon's *The Great World Theatre* in a cathedral he is merely imitating with conscious art the naive habit that the ancient theatre had of playing cuckoo and laying its eggs of art in amphitheatres, chancels, inn yards, bear-pits, tennis courts, market places, and court ballrooms

Enter the Régisseur or Director.—Yet, in a narrow sense, there are modern tendencies in the theatre—two major tendencies, both founded on a new attitude towards the complex business of getting actors to speak lines in an effective *ensemble* The new attitude is seen in the commanding presence of a director Some one has always insisted that the actors learn their lines, speak them with a certain skill, and walk where they will not trip over one another's heels or become entangled with the properties. But the commanding director—or *régisseur*—is the notable contribution of the theatre of the past half century From Duke George II. of the little German State of Meiningen—who fused supers into true mobs, put ceilings on box sets, and created the first modern *ensemble* acting in the middle '70s—through Otto Brahm, first master of naturalism at the beginning of the 20th century, Max Reinhardt, Brahm's disciple to begin with, then pioneer in every form of theatre from cabaret to cathedral and little theatre to circus, Meyerhold the Russian, who preached and performed the "theatre theatrical"—from these masters on to the director of the tiniest of community theatres in some Californian town, the *régisseur* has taken his place as the centre of the modern theatre. His business has been to dominate, synthesize, and unify each production, and thus to bring forth a single work of theatrical art in-instead of a histrionic accident

Realism Versus the Theatric.—Without the *régisseur* neither of the two great schools of modern production could have developed A single mind was needed to shape the performance, set its character, give it its pace, provide its atmosphere in scenery and lights. It did not matter whether the result was to be a realistic production or a production in which the true theatricalism of the stage was to be liberated—one creative spirit had to dominate.

In the terms of the past century, realism is a much older thing than the theatric, although the theatric goes far deeper into the historic past Realism is likely to dominate the stage as long as machine civilization dominates life It has already come to a fine perfection, and we are more familiar with it than with the theatric. We have seen realism at its height in Stanislavsky of the Moscow Art theatre, and occasionally in David Belasco or Basil Dean We have not seen much theatric acting outside Russia and Germany. In America and England the theatric and imaginative movement has expressed itself largely in things of the eye—in the scenery of the new stage-craft The battle of realism and the theatric—first with a common enemy, then with each other—can in many ways be seen best through the activities of the *régisseurs* of scenery, the stage designers who have given it outward physical form. Nothing but the theatre could harbour artistic tendencies so diverse. But, though one is photographic and one is imaginative, both began in fierce opposition to the theatre of Victorian days. The thing that both hated in this theatre was typified in its scenery, ugly, unillusive, accidental.

Thus two very different types of artists were leagued as allies. One was the realist, like Belasco, who wanted solid, plausible rooms on the stage. The other was the man of imagination, like Gordon Craig, who wanted beauty or something full of expressive artifice There was a little of each in the first great *régisseur* of the 20th century, Max Reinhardt. Together, the realist and the artist of the imagination banished the mechanism of the older stage. They banned false perspective and shallow pretence, muddy colour on flapping backdrops.

Realism triumphed first It had the great dramatists of the day behind it, and the mood of 20th century audiences. Maeterlinck and von Hofmannstahl and d'Annunzio put up an anaemic front to Ibsen, Hauptmann, Sudermann, Brieux, Pinero, Jones, and Shaw The *régisseur* developed actors who could convey emotion by the quiver of an eyelash, and he found ways to surround them with the solid world of reality

Mechanical Progress.—But how were the solid columns, weighty staircases, well-braced walls to be moved? How were scenes to be shifted quickly and economically? The problem was not alone a problem for the realistic producer, for when the *régisseur* put on Shakespeare the new settings were solid, plastic, three-dimensional, and he had dozens of these scenes and no long intermissions in which to change them The answer—the typical answer—was modern machinery America led—for just a moment or two in 1888—when Steele MacKaye, *régisseur,* actor, playwright, painter and mechanist, installed his double elevator stage in the Madison Square Theatre, New York, to shift scenery, actors and all. The great bulk of mechanical reform, however, has come from Germany, and dates from 1896 when Lautenschlaeger of Munich borrowed the revolving stage from Japan Other scene-shifting machines from Germany include the sliding stage, which carries whole settings on great wagons, and sinking stages, which bring up the scenery from the basement Arthur Hopkins, the first American *régisseur* of imagination to follow MacKaye, introduced, about 1914, stages that swung on pivots, and Lee Simonson, the American designer, has made most ingenious use of small revolving units in Theatre Guild productions such as *Peer Gynt.* (*See* STAGE DESIGN)

Progress in Lighting.—Even more energy and resourcefulness has gone into the improvement of lighting equipment since the days of gas, and this has served both the realist and the producer of imagination. The first notable attempt was made in Germany by the Venetian, Fortuny. His aim was to provide diffused and softened light, more like the reflected sunlight of a shaded spot. He threw all the light rays of an arc upon screens of coloured silk which reflected them upon the stage. His sky-dome or *Kuppelhorizont* further diffused the light while producing an illusive sky of almost infinite depth From the mechanism of Fortuny and the ideas of Gordon Craig's great rival, Adolphe Appia—who first called for the shadowed, sculpturesque lighting that comes from large sources of illumination, instead of the blank glare of the footlights—electrical invention has gone on to a surprising degree of perfection in Germany and America. Through Max Hasait and Adolph Linnebach, both working at Dresden in hot rivalry, devices were at last perfected for projecting scenery by means of light on to backdrops or cycloramas. Simonson made fine use of the Linnebach process in *Back to Methuselah* and *Peer Gynt.*

There is, after all, a considerable difference between a decoration thrown on a backdrop by electric light and interiors so solid and heavy that they must be shifted by machinery And yet both extremes fall easily within the limits of the revolt which realist and theatricalist began in the name of the new stagecraft. Even the old-fashioned backdrops of the opera house, painted in false perspective, have their place in the modern movement of the imagination if only they are painted with the boldness, the dramatic vigour, and the expressive colour of a Russian like Bakst or Roerich or Golovin If the artist can create an effect upon the stage just as characteristic of the play and its emotion as anything the actors may do, then he has done the work expected of him. The medium and the method do not matter

Pioneers of the New Stage-craft.—This was not quite so clear when Gordon Craig and Adolph Appia began their campaign of scenic enlightenment about the beginning of the 20th century.

All about them the stage was filled with flat and shallow artificiality There was neither beauty nor truth to life in the jaundiced meadows and mildewed mountains and splayed rooms which the hack scene painters spread over backdrops and wings in very, very false perspective. The realist and the imaginative artist had to hate them equally Craig and Appia might have accepted the stage conventions of the old theatre—the simple flats and backdrops, and awakened them to new life as the Russians did Instead they fought them, and fought them on the one legitimate issue on which they can be fought Paintings in two dimensions do not and cannot harmonize with three dimensional actors. So away with false perspective and its painted shadows. Make room for solid plastics, for rocks and walls against which the actor may lean

Gordon Craig did a great deal more than argue against backdrops and wings In his articles and books he showed that the theatre is a composite art made up of the contributions of playwright and actor and painter and musician. He demanded unity upon the stage and he declared that the ideal artist of the theatre must be the man who can write the play, direct the actors, design the scenery and lights, and provide any other element such as the music or the dance that may be needed Only in this fashion can the theatre have the creative unity which is at its heart. And in all his writing and through all his brilliant designs, Craig sought to interpret in as dramatic a fashion as possible the emotion of the play.

Appia, a Swiss doctor, who began theorizing and sketching in the early '90s, stood likewise against false perspective and in favour of the plastic stage. Like Craig, he was truly a *régisseur.* His great contribution was a sense for the value of light. In his book describing and picturing the production of Wagner's music-dramas, Appia provided many appropriate and striking sketches, dictating the movements of actors as well as lights He showed how spotlights, used instead of footlights, produce shadows; how light and shadow give a sculpturesque quality to everything on the stage, and how changes in the light can indicate the passage of time and the development of the drama. To demonstrate this, he drew a series of sketches of scenes from Wagner's music-dramas following the light changes throughout each act.

When the theories of Craig and Appia annihilated the old stage setting, they opened the way for something they were not the least interested in—realism. Fortunately they also provided the corrective for it. When realism is most complete it is at its worst It then furnishes an absolute photograph of life. A room becomes a junk shop. It is solid, real and wooden, and utterly confused. There are so many knick-knacks about that you can hardly find the actors The eye is tempted to wander off and count the bowls of flowers and admire the woodwork and discover curios all over the place. Belasco and all the realists have now learned better than this So far as America is concerned, Arthur Hopkins and the artists of the new stage-craft have taught them how to make a room seem real and plausible and yet never distracting, and how to make it express something of the drama that goes on within

Making Scenery Abstract.—The modern theatre has been quick to recognize that the mood created by a background is the important thing, and that, generally speaking, the less the material world is involved, the more the actor can summon up an ideal world of the theatrical imagination. Directors and designers tended, therefore, towards experiments with more and more abstract settings Craig began with curtains, using them for walls. In a scene for a modern play, Robert Edmond Jones painted his curtains brown and green and hung them in folds that, under proper lighting, suggested a forest Other artists—Norman Wilkinson, for example, working in England under its one modern *régisseur,* Granville Barker—go a step further and treat curtains frankly as curtains, painting them with a landscape or a formal arrangement of stars, and then—so there cannot be the least possible mistake about it—draping the curtains in folds, and banishing even the quasi-illusion of the old backdrop.

Screens can be used even more abstractly. About 1912, Craig worked out a scheme for equipping a theatre with a set of folding screens of all sizes which could be rearranged in an endless variety of ways When Stanislavsky tried to use this system of screens for *Hamlet* at the Moscow Art theatre, he found grave difficulties in the way of its practical employment. These difficulties were largely removed in a scheme devised by a pupil of Craig's, Sam Hume, which he used at the Detroit Arts and Crafts theatre.

In all this talk of scenery, you must note implication after implication of how the *régisseur* will direct the company towards an art far, far removed from the realism of the Moscow Art theatre. When the theatre goes still further into the abstract or the fantastic in stage setting, it must carry the actor along with it, or it is nothing Already designers have thrust upon the stage the expressionistic methods of modern painters like Picasso —himself a designer for the Russian ballet of Diaghileff In America, and in most of the Continent outside Russia, the *régisseurs* have done little to match these backgrounds with acting The outstanding exceptions—Meyerhold, Yevreynoff, Komisarshefsky, Tairoff and Zemach, all of Russia—have laboured to infuse into the actor and the *ensemble* a stylized vitality which distinguishes their performances from anything in the Western world.

Expressionism and Constructivism.—Expressionism, whether of acting or scenery, postulates that the expression of inner emotion—which ought to be the emotion of the playwright and his play—comes before any resemblance to the outer aspect of life. Expressionistic productions use distortion to arrest and excite the attention. Doorways assume strange forms, as in that notable attempt in *Macbeth* which Robert Edmond Jones and Arthur Hopkins made in New York some years ago without acting to back them up Walls topple The floor shoots up at weird angles. Lights flare in with no relation to reality, and shift in colour almost word by word The make-up of the actors is startlingly obvious in its distorted lines, and the clothes of even modern characters are painted with high lights and shadows.

One can almost go back to Appia for the beginnings of constructivism, for Appia was the first to stress the necessity of varied levels on the stage They have become increasingly important in the work of the more radical *régisseurs.* Leopold Jessner, Germany's outstanding director since Reinhardt, added these levels to the formal stage of the more conservative expressionists. By using steps and parapets, he was able to move his people in three dimensions, and make their physical relationships more vivid and significant In each of his Shakespeare productions he stuck to a single arrangement of steps, upon which he arranged a few of Emil Pirchan's simply sketched indications of *locale,* all within the neutral wall of the often unlighted cyclorama.

From Jessner one leaps to Russia to find Meyerhold, a great theatrical pioneer, developing in constructivism an art which seems to steal its settings from the American skyscraper. High platforms, skeletonized structures, inclined planes, all manner of bare, unsentimentalized construction provide the footing as well as the background for the actors, and three or four *locales* are shown at one time—a trick of the Renaissance. Tairoff mingles canvas expressionism with this when he mounts Eugene O'Neill's *The Hairy Ape* or *Desire under the Elms.* In the musical studio of the Moscow Art theatre Dantchenko has refined and humanized constructivism in performances of *Lysistrata* and *Carmen.*

New Theatres for Old.—Certain attempts at formalizing the existing stage carry us clear out of this phase and into new types of playhouses Robert Edmond Jones's *Hamlet,* for instance, turned a Romanesque hall into a permanent setting for the whole drama. Such a scheme makes no pretence at the illusion of turrets, woods or any place except the theatre, tinged with the colour and mood of the drama. This recognition of the playhouse as a place of frank make-believe has carried many modern directors into experiments in theatre architecture that recall the stages of Greece and Elizabethan England. Reinhardt, after producing Greek tragedy in the one-ring circus buildings of Germany, reconstructed one of these houses into the Grosses Schauspielhaus. Here the actors could appear on the orchestra floor in the midst of the audience or retreat to a fully equipped modern stage with

sky-dome and revolving floor

Half a dozen artists have designed theatres of even more revolutionary character. One of these, not yet built, however, is Norman-Bel Geddes's project for a stage in the corner of a sky-dome completely arching in the auditorium as well. The stage itself sinks into the basement for changes of scene to be made by means of rolling platforms already set. MacKaye's Spectatorium, conceived and partially built for the World's Fair in Chicago, was to seat 10,000 people. The stage itself was to introduce a number of reforms now adopted abroad—the sky-dome, the adaptable proscenium opening and fore stage, the cloud machine, and a sliding stage on wheels The whole stage could be submerged in water for the discovery of America by Columbus.

Europe created two theatres of outstanding novelty in the Vieux Colombier of Copeau and the Theater in dem Redoutensaal opened in Vienna by Adolf Vetter, then head of the State theatres. The Vieux Colombier was a tiny playhouse without a proscenium opening in which the audience and stage were contained in a single room. The stage itself was provided with a permanent architectural setting of steps and balcony which could be converted, for example, from a classic exterior into a scene for *Twelfth Night* by altering parts of the decoration.

The Theater in der Redoutensaal is again a theatre with no proscenium and, therefore, no fourth wall and no peep-show. At one end of this great and glorious ballroom of Maria Theresa, Vetter and Oberbaurat Sebastien Heinrich placed an acting platform without proscenium or "flies" Upon this platform is a curving wall perhaps 15 ft high, carrying out the decorative motifs of the hall and making a permanent background for the stage In the middle, double stairways curve up to a balcony above. Upon the balcony are great doors leading to other rooms. The shell of cream and gold wall is pierced by openings for doors and windows Screens or simple set-pieces serve to vary this setting, and to indicate mood and place. *The Marriage of Figaro* was there presented by the forces of the State opera, and Max Reinhardt has staged many classic comedies in the Redoutensaal.

The bulk of this effort to match the realistic theatre with a theatre of imagination has gone forward unsupported by proper plays. The classics have served best Some modern dramas have been badly distorted to fit them to the Procrustean bed of expressionism In Germany a certain number of playwrights, led by Georg Kaiser and Walter Hasenclever, have made valiant and none too successful efforts to provide free and vivid plays of to-day cast in a nervous, fast-moving, subjective form. The success of the Russians in matching plays to constructivist production had not been so notable as to pass the frontiers by 1928. The only distinctly promising efforts towards new dramatic form have come from America and largely from the pen of one writer, Eugene O'Neill Elmer Rice's *The Adding Machine* and George S. Kaufman and Marc Connelly's *Beggar on Horseback*, adapted from a German original, have succeeded in enkindling a public response, but the pioneer work of John Howard Lawson, Francis E Faragoh, John Dos Passos, and Em Jo Bassche has failed to meet the requirements of the audiences of to-day. O'Neill's expressionistic drama *The Hairy Ape*, his constructivist experiment *Desire Under the Elms*, his drama of masks *The Great God Brown*, his nine-act exposition of spoken thoughts *Strange Interlude*, and his printed play *Lazarus Laughed*, seem the only completely mastered attempts of a playwright to strike out along the paths that modern pioneers in direction, scenery and acting have marked out.

DIRECTION AND ACTING

Theatrical art has always been collective, arising only where poetical-dramatic talent was actively combined with the actor's The basis of a play is always a dramatic conception; a general artistic sense is imparted to the theatrical action by the unifying, creative genius of the actor Thus the actor's dramatic activity begins at the foundation of the play In the first place, each actor, either independently or through the theatre manager, must probe for the fundamental motive in the finished play—the creative idea that is characteristic of the author and that reveals itself as the germ from which his work grows organically. The motive of the play always holds the character developing before the spectator; each personality in the work takes a part conforming to his own character; the work, then developing in the appointed direction, flows on to the final point conceived by the author The first stage in the work of the actor and theatre manager is to probe for the germ of the play, investigating the fundamental line of action that traverses all of its episodes and is therefore called by the writer its transparent effect or action. In contrast to some theatrical directors, who consider every play only as material for theatrical repetition, the writer believes that in the production of every important drama the director and actor must go straight for the most exact and profound conception of the mind and ideal of the dramatist, and must not change that ideal for their own. The interpretation of the play and the character of its artistic incarnation inevitably appear in a certain measure subjective, and bear the mark of the individual peculiarities of the manager and actors; but only by profound attention to the artistic individuality of the author and to his ideal and mentality, which have been disclosed as the creative germ of the play, can the theatre realize all its artistic depth and transmit, as in a poetical production, completeness and harmony of composition Every part of the future spectacle is then unified in it by its own artistic work; each part, in the measure of its own genius, will flow on to the artistic realization aimed at by the dramatist

The actor's task, then, begins with the search for the play's artistic seed. All artistic action—organic action, as in every constructive operation of nature—starts from this seed at the moment when it is conveyed to the mind On reaching the actor's mind, the seed must wander around, germinate, put out roots, drinking in the juices of the soil in which it is planted, grow and eventually bring forth a lively flowering plant Artistic process must in all cases flow very rapidly, but usually, in order that it may preserve the character of the true organic action and may lead to the creation of life, of a clear truly artistic theatrical image, and not of a trade substitute, it demands much more time than is allotted to it in the best European theatres That is why in the writer's theatre every dramatization passes through eight to ten revisions, as is also done in Germany by the famous theatre manager and theorist, K Hagemann Sometimes even more than ten revisions are needed, occasionally extending over several months But even under these conditions, the creative genius of the actor does not appear so freely as does, for instance, the creative genius of the dramatist Bound by the strict obligations of his *collectif*, the actor must not postpone his work to the moment when his physical and psychic condition appears propitious for creative genius Meanwhile, his exacting and capricious artistic nature is prompted by aspirations of his artistic intuition, and in the absence of creative genius is not reached by any effort of his will. He is not aided in that respect by outward technique—his skill in making use of his body, his vocal equipment and his powers of speech

The Artistic Condition.—But is it really impossible? Are there no means, no processes that sensibly would help us, and spontaneously lead to that artistic condition which is born of

genius without any effort on its part? If that capacity is unattainable all at once, by some process or other, it may, perhaps, be acquired in parts, and through progressive stages may perfect those elements out of which the artistic condition is composed, and which are subject to our will Of course the general run of acting does not come into being from this genius, but cannot such acting, in some measure, be brought by it near to what is evidence of genius? These are the problems which presented themselves to the writer about 20 years ago, when reflecting on the external obstacles that hamper actors' artistic genius, and partly compel substitution of the crude outward marks of the actor's profession for its results. They drove him to the rediscovery of processes of external technique, *i.e.*, methods proceeding from consciousness to sub-consciousness, in which domain flow nine-tenths of all real artistic processes. Observations both upon himself and other actors with whom he happened to rehearse, but chiefly upon growing theatrical skill in Russia and abroad, allowed him to do some generalizing, which thereupon he verified in practice

The first is that, in an artistic condition, full freedom of body plays a principal rôle, *i e*, the freedom from that muscular strain which, without our knowing it, fetters us not only on the stage but also in ordinary life, hindering us from being obedient conductors of our psychic action. This muscular strain, reaching its maximum at those times when the actor is called upon to perform something especially difficult in his theatrical work, swallows up the bulk of this external energy, diverting him from activity of the higher centres This teaches us the possibility of availing ourselves of the muscular energy of our limbs only as necessity demands, and in exact conformity with our creative efforts

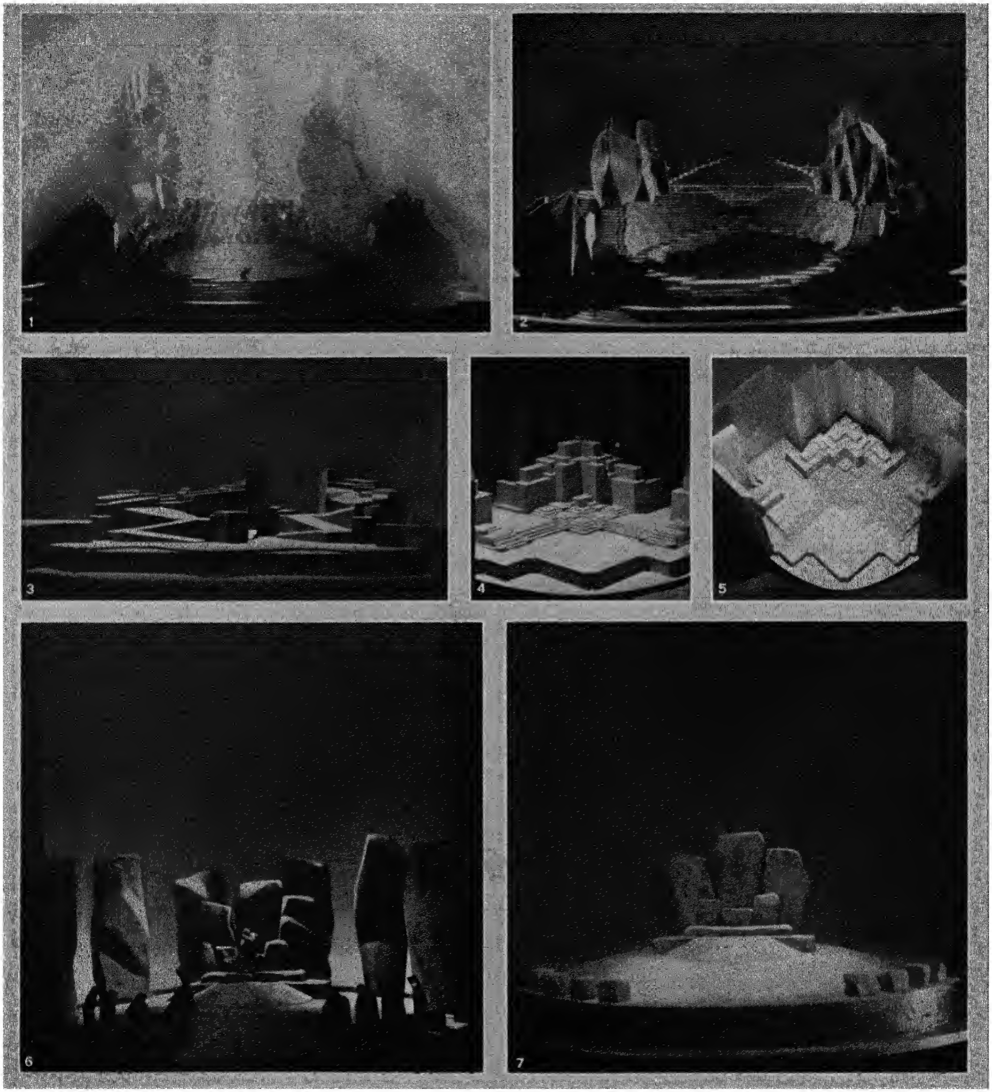
The second observation is that the flow of the actor's artistic force is considerably retarded by the visual auditorium and the public, whose presence may hamper his outward freedom of movement, and powerfully hinder his concentration on his own artistic taste. It is almost unnecessary to remark that the artistic achievement of great actors is always bound by the concentration of attention to the action of their own performance, and that when in that condition, *i e*, just when the actor's attention is taken away from the spectator, he gains a particular power over the audience, grips it, and compels it to take an active share in his artistic existence This does not mean, of course, that the actor must altogether cease to feel the public; but the public is concerned only in so far as it neither exerts pressure on him nor diverts him unnecessarily from the artistic demands of the moment, which last might happen to him even while knowing how to regulate his attention The actor suitably disciplined must automatically restrict the sphere of his attention, concentrating on what comes within this sphere, and only half consciously seizing on what comes within its aura. If need be, he must restrict that sphere to such an extent that it reaches a condition that may be called *public solitude*. But as a rule this sphere of attention is elastic, it expands or contracts for the actor, with regard to the course of his theatrical actions Within the boundary of this sphere, as one of the actual aspects of the play, there is also the actor's immediate central *object of attention*, the object on which, somehow or other, his will is concentrated at the moment with which, in the course of the play, he is in inward communication This theatrical sympathy with the object can only be complete when the actor has trained himself by long practice to surrender himself in his own impressions, and also in his reactions to those impressions, with maximum intensity· only so does theatrical action attain the necessary force, only so is created between the actual aspects of the play, *i e*, between the actors, that link, that living bond. which is essential for the carrying through of the play to its goal, with the general maintenance of the rhythm and time of each performance.

Concentration.—But whatever may be the sphere of the actor's attention, whether it confines him at some moments to public solitude, or whether it grips the faces of all those before the stage, dramatic artistic genius, as in the preparation of the part so in its repeated performance, requires a full concentration of all the mental and physical talents of the actor, and the participation of the whole of his physical and psychic capacity. It takes hold of his sight and hearing, all his external senses, it draws out not only the periphery but also the essential depth of his existence, and it evokes to activity his memory, imagination, emotions, intelligence and will. The whole mental and physical being of the actor must be directed to that which is derived from his facial expression. At the moment of inspiration, of the involuntary use of all the actor's qualities, at that moment he actually exists. On the other hand, in the absence of this employment of his qualities, the actor is gradually led astray along the road leading to time-honoured theatrical traditions; he begins to "produce" wherever he sees them, or, glancing at his own image, imitates the inward manifestations of his emotions, or tries to draw from himself the emotions of the perfected part, to "inspire" them within himself But when forcing such an image by his own psychic equipment, with its unchanging organic laws. he by no means attains that desired result of artistic genius, he must present only the rough counterfeit of emotion, because emotions do not come to order By no effort of conscious will can one awake them in oneself at a moment, nor can they ever be of use for creative genius striving to bring this about by searching the depths of its mind A fundamental axiom, therefore, for the actor who wishes to be a real artist on the stage, may be stated thus he must not play to produce emotions, and he must not involuntarily evoke them in himself

Activity of Imagination.—Considerations on the nature of artistically gifted people, however, inevitably open up the road to the possession of the emotion of the part This road traverses activity of imagination, which in most of its stages is subject to the action of consciousness. One must not suddenly begin to operate on emotion, one must put oneself in motion in the direction of artistic imagination, but imagination—as is also shown by observations of scientific psychology—disturbs our aberrant memory, and, luring from the hidden recesses beyond the boundaries of its sense of harmony whatever elements there may be of proved emotions, organizes them afresh in sympathy with those that have arisen in our imagery So surrounded within our figures of imagination, without effort on our part, the answer to our aberrant memory is found and the sounds of sympathetic emotion are called out from us This is why the creative imagination presents itself afresh, the indispensable gift of the actor Without a well developed, mobile imagination, creative faculty is by no means possible, not by instinct nor intuition nor the aid of external technique In the acquiring of it, that which has lain dormant in the mind of the artist is, when immersed in his sphere of unconscious imagery and emotion, completely harmonized within him.

This practical method for the artistic education of the actor, directed by means of his imagination to the storing up of effective memory, is sufficiently enlarged upon, his individual emotional experience, by its limits, actually leads to the restriction of the sphere of his creative genius, and does not allow him to play parts dissimilar to those of his psychic harmony. This opinion is fundamental for the clearing away of misunderstandings of those elements of reality from which are produced fictitious creations of imagination, these are also derived from organic experience, but a wealth and variety of these creations are only obtained by combinations drawn from a trial of elements The musical scale has only its basic notes, the solar spectrum its radical colours, but the combination of sounds in music and of colours in painting are infinite One can in the same way speak of radical emotions preserved in imaginative memory, just as the reception in imagination of outward harmony remains in the intellectual memory; the sum of these radical emotions in the inner experience of each person is limited, but the shades and combinations are as infinite as the combinations that create activity of imagination out of the elements of inward experience.

Certainly, but the actor's outward experience—*i.e.*, his sphere of vital sensations and reflections—must always be elastic, for only in that condition can the actor enlarge the sphere of his creative faculty. On the other hand, he must judiciously develop his imagination, harnessing it again and again to new propositions.



SETTINGS DESIGNED BY NORMAN BEL GEDDES; PHOTOGRAPHS, FRANCIS BRUGUIÈRE

STAGE STRUCTURES OF THE MODERN THEATRE

1, 2. Scene in "The Divine Comedy" by Dante, as dramatized and projected for production by Norman Bel Geddes. The stage rises around a pit in its centre; changes of scene are made by lighting and the massing of actors. The drawings represent the moment when the earth opens to receive Dante. The actors, who prior to this point have covered the pit of light completely, withdraw in groups, then crumple up and disappear leaving the void for Dante and Virgil to descend into. **3.** Model for "Lazarus Laughed," a play by Eugene O'Neill planned for production in 1927. The nine scenes are made by the rearrangement of two monumental units which can be turned to different positions in a few seconds by a controlling motor. They are set off with properties and decorations carried by the supers, against the cyclorama, with immense variety of effect. In this photograph of the model the proscenium arch has been removed. **4, 5.** Model for the stage structure of "Jeanne D'Arc," a play by Mercedes de Acosta, produced at the Porte Saint Martin Théâtre, Paris, 1925, under the direction of Norman Bel Geddes. On this single setting ten scenes are played, each of a different nature. Changes are made in full view of the audience by properties carried by actors and by subtle lighting of architectural embryos in the rear of the stage which are concealed in shadow when not intended to be seen. **6, 7.** Model for Shakespeare's "King Lear." A circular ramped platform, a geometrical mound and huge variformed monoliths, that are easily movable into various positions, are set against a vast space of darkness. The scenes, appearing in pagan colours, fade into one another without pause. The mood achieved by the setting is emphasized by the costumes which are so heavy they seem to hold the body inside fast to the earth, suggesting figures scarcely human

THEATRE ARCHITECTURE

MODERN INTERIORS OF THEATRES FOR MUSICAL COMEDY, OPERA AND DRAMA

1. The Grosses Schauspielhaus, Berlin, a circus building converted into a theatre for Max Reinhardt. The acting space is in the midst of the spectators; steps lead to a main stage fully equipped with a plaster sky-dome and a revolving stage. Architect, Hans Poelzig
2. The Ziegfield Theatre, New York city, a musical comedy house with an elliptical shaped auditorium fancifully decorated. Architects, Joseph Urban and Thomas W. Lamb
3. The Kroll Opera House, Berlin, an intimate opera house expressing severe German modernism. The second balcony is over the boxes. Architect, Oskar Kaufmann
4. Rendering of a projected theatre designed for Max Reinhardt by Joseph Urban. A large part of the audience is niched in boxes invisible to one another but with a clear view of the stage. Runways lead from the sides of the stage to the back
5. The Guild Theatre, New York city, a period interior. Architect, C. Howard Crane
6. The Piccadilly Theatre, London, an interior in the more subdued convention of modern English design. Architect, Edward A. Stone
7. The Theater in dem Redoutensaal, Vienna, a ballroom in the Hofburg Palace converted into a theatre without a proscenium for formalized production. Here under the glow of crystal chandeliers, and with wall hangings of Gobelin tapestries, Max Reinhardt produced classic and modern comedy. Architect, Sebastian Heinrich
8. The John Golden Theatre, New York, an excellently arranged auditorium along the prevailing American lines, with a rather emphatic period treatment. Architect, Harrison G. Wiseman
9. Concert House Vestibule, Stockholm. Architect, Ivan Jengborn.

But, in order that that imaginary union which is the actor's very foundation, produced by the creative genius of the dramatist, should take hold of him emotionally and lead him on to theatrical action, it is necessary that the actor should "swing toward" that union, as toward something as real as the union of reality surrounding him.

The Emotion of Truth.—This does not mean that the actor must surrender himself on the stage to some such hallucination as that when playing he should lose the sense of reality around him, to take scenery for real trees, etc On the contrary, some part of his senses must remain free from the grip of the play to control everything that he attempts and achieves as the performer' of his part. He does not forget that surrounding him on the stage are decorations, scenery, etc , but they have no meaning for him. He says to himself, as it were: "I know that all around me on the stage is a rough counterfeit of reality It is false. But if all should be real, see how I might be carried away to some such scene; then I would act " And at that instant, when there arises in his mind that artistic "suppose," encircling his real life, he loses interest in it, and is transported to another plane, created for him, of imaginary life. Restored to real life again, the actor must perforce modify the truth, as in the actual construction of his invention, so also in the survivals connected to it. His invention can be shown to be illogical, wide of the truth—and then he ceases to believe it Emotion rises in him with invention; *i e.*, his outward regard for imagined circumstances may be shown as "determined" without relation to the individual nature of a given emotion Finally, in the expression of the outward life of his part, the actor, as a living complex emotion, never making use of sufficient perfection of all his bodily equipment, may give an untrue intonation, may not keep the artistic mean in gesticulation and may through the temptation of cheap effect drift into mannerism or awkwardness

Only by a strongly developed sense of the truth may he achieve that, in order that every one of his poses, and every gesture may be outwardly realistic, *i e*, he may express the condition representing the character, and may not serve, like the conventional theatrical gestures and poses of every race, a single inward beauty.

Internal Technique.—The combination of all the abovenamed procedure and habits also composes the actor's external technique. Parallel with its development must go also the development of internal technique—the perfecting of that bodily equipment which serves for the incarnation of the theatrical image created by the actor, and the exact, clear expression of his external consciousness With this aim in view the actor must work out within himself not only the ordinary flexibility and mobility of action, but also the particular consciousness that directs all his groups of muscles, and the ability to feel the energy transfused within him, which, arising from his highest creative centres, forms in a definite manner his mimicry and gestures, and, radiating from him, brings into the circle of its influence his partners on the stage and in the auditorium. The same growth of consciousness and fineness of internal feelings must be worked out by the actor in relation to his vocal equipment Ordinary speech—as in life, so on the stage—is prosaic and monotonous; in it words sound disjointed, without any harmonious stringing together in a vocal melody as continuous as that of a violin, which by the hand of a master violinist can become fuller, deeper, finer and more transparent, and can without difficulty run from the higher to the lower notes and vice versa, and can alternate from pianissimo to forte To counteract the wearisome monotony of reading, actors often elaborate, especially when declaiming poetry, with those artificial vocal *fioritures,* cadences and sudden raising and lowering of the voice, which are so characteristic of the conventional, pompous declamation, and which are not influenced by the corresponding emotion of the part, and therefore impress the more sensitive auditors with a feeling of unreality.

But there exists another natural musical sonorousness of speech, which we may see in great actors at the moment of their own true artistic elation, and which is closely knit to the internal sonorousness of their rôle. The actor must develop within himself this natural musical speech by practising his voice with due regard to his sense of reality, almost as much as a singer. At the same time he must perfect his elocution. It is possible to have a strong, flexible, impressive voice, and still distort speech, on the one hand by incorrect pronunciation, on the other by neglect of those almost imperceptible pauses and emphases through which are attained the exact transmission of the sense of the sentence, and also its particular emotional colouring In the perfect production of the dramatist, every word, every letter, every punctuation mark has its part in transmitting his inward reality; the actor in his interpretation of the play, according to his intelligence, introduces into each sentence his individual nuances, which must be transmitted not only by the motions of his body, but also by artistically developed speech He must bear this in mind, that every sound which goes to make a word appears as a separate note, which has its part in the harmonious sound of the word, and which is the expression of one or other particle of the soul drawn out through the word. The perfecting, therefore, of the phonetics of speech cannot be limited to mechanical exercise of the vocal equipment, but must also be directed in such a way that the actor learns to feel each separate sound in a word as an instrument of artistic expression But in regard to the musical tone of the voice, freedom, elasticity, rhythm of movement and generally all external technique of dramatic art, to say nothing of internal technique, the present day actor is still on a low rung of the ladder of artistic culture, still far behind in this respect, from many causes, the masters of music, poetry and painting, with an almost infinite road of development to travel

Production.—It is evident that under these conditions, the staging of a play, which will satisfy highly artistic demands, cannot be achieved at the speed that economic factors unfortunately make necessary in most theatres. This creative process, which every actor must go through, from his conception of the part to its artistic incarnation, is essentially very complicated, and is hampered by lack of perfection of outward and inward technique It is also much hindered by the necessity of fitting in the actors one with another—the adjustment of their artistic individualities into an artistic whole

Responsibility for bringing about this accord, and the artistic integrity and expression of the performance rests with the theatre manager During the period when the manager exercised a despotic rule in the theatre, a period starting with the Meiningen players and still in force even in many of the foremost theatres, the manager worked out in advance all the plans for staging a play, and, while certainly having regard to the existing cast, indicated to the actors the general outlines of the scenic effects, and the *mise-en-scène*. The writer also adhered to this system, but now he has come to the conclusion that the creative work of the manager must be done in collaboration with the actor's work, neither ignoring nor confirming it To encourage the actor's creative genius, to control and adjust it, ensuring that this creative genius grows out of the unique artistic germ of the drama, as much as the external building up of the performance—that in the opinion of the writer is the problem of the theatre director to-day

The joint work of the director and actor begins with the analysis of the drama and the discovery of its artistic germ, and with the investigation of its *transparent effect* The next step is the discovery of the transparent effect of individual parts—of that fundamental will direction of each individual actor, which, organically derived from his character, determines his place in the general action of the play. If the actor cannot at once secure this transparent effect, then it must be traced bit by bit with the manager's aid—by dividing the part into sections corresponding to the separate stages of the life of the particular actor—from the separate problems developing before him in his struggle for the attainment of his goal. Each such section of a part or each problem, can, if necessary, be subjected to further psychological analysis, and sub-divided into problems even more detailed, corresponding to those separate mind actions of the performer out of which stage life is summed up. The actor must catch the *mind axes* of the emotions and temperaments, but not the emotions and temperaments that give colour to these sections of the part. In other words, when studying each portion of his part, he must

ask himself what he wants, what he requires as a performer of the play and which definite partial problem he is putting before himself at a given moment. The answer to this question should not be in the form of a noun, but rather of a verb: "I wish to obtain possession of the heart of this lady"—"I wish to enter her house"—"I wish to push aside the servants who are protecting her," etc Formulated in this manner, the mind problem, of which the object and setting, thanks to the working of his creative imagination, are forming a brighter and clearer picture for the actor, begins to grip him and to excite him, extracting from the recesses of his working memory the combinations of emotions necessary to the part, of emotions that have an active character and mould themselves into dramatic action. In this way the different sections of the actor's part grow more lively and richer by degrees, owing to the involuntary play of the complicated organic survivals By joining together and grafting these sections, the *score of the part* is formed, the scores of the separate parts, after the continual joint work of the actors during rehearsals and by the necessary adjustment of them one with another, are summed up in a single *score of the performance*.

The Score Condensed.—Nevertheless, the work of the actors and manager is still unfinished. The actor is studying and living in the part and the play deeper and deeper still, finding their deeper artistic motives; so he lives in the score of his part still more profoundly. But the score of the part itself and of the play are actually subject by degrees during the work to further alterations As in a perfect poetical production there are no superfluous words but only those necessary to the poet's artistic scheme, so in a score of the part there must not be a single superfluous emotion but only emotions necessary for the *transparent effect*. The score of each part must be condensed, as also the form of its transmitting, and bright, simple and compelling forms of its incarnation must be found Only then, when in each actor every part not only organically ripens and comes to life but also all emotions are stripped of the superfluous, when they all crystallize and sum up into a live contact, when they harmonize amongst themselves in the general tune, rhythm and time of the performance, then the play may be presented to the public

During repeated presentations the theatrical score of the play and each part remains in general unaltered. But that does not mean that from the moment the performance is shown to the public the actor's creative process is to be considered ended, and that there remains for him only the mechanical repetition of his achievement at the first presentation. On the contrary, every performance imposes on him creative conditions; all his psychical forces must take part in it, because only in these conditions can they creatively adapt the score of the part to those capricious changes which may develop in them from hour to hour, as in all living nervous creatures influencing one another by their emotions, and only then can they transmit to the spectator that invisible something, inexpressible in words, which forms the spiritual content of the plays And that is the whole origin of the substance of dramatic art

As regards the outward arrangements of the play—scenery, theatrical properties, etc —all are of value in so far as they correspond to the expression of dramatic action, *i.e*, to the actors' talents; in no case may they claim to have an independent artistic importance in the theatre, although up to now they have been so considered by many great scene painters The art of scene painting, as well as the music included in the play, is on the stage only an auxiliary art, and the manager's duty is to get from each what is necessary for the illumination of the play performed before an audience, while subordinating each to the problems of the actors. (*See* ACTING; MOTION PICTURES: *Acting* and *Direction*) (C. St)

THE ACTOR

It is to the actor and to no one else that the theatre belongs. This does not mean, of course, the professional actor alone, but the actor as poet, as director, stage-manager, musician, scene-designer, painter, and, certainly not least of all, the actor as spectator, for the contribution of the spectators is almost as important as that of the cast The audience must take its part in the play if we are ever to see arise a true art of the theatre—the oldest, most powerful, and most immediate of the arts, combining the many in one

We all bear within us the potentiality for every kind of passion, every fate, every way of life Nothing human is alien to us. If this were not so, we could not understand other people, either in life or in art. But inheritance and upbringing foster individual experiences and develop only a few of our thousands of possibilities The others gradually sicken and die.

Bourgeois life to-day is narrowly circumscribed, and poor in feeling. Out of its poverty it has made merely virtues through which it pushes its way, severe and upright. The normal man generally feels once in his life the whole blessedness of love, and once the joy of freedom. Once in his life he hates bitterly Once with deep grief he buries a loved one, and once, finally, he dies himself That gives all too little scope for our innate capacity to love, hate, enjoy, and suffer We exercise daily to strengthen our muscles and sinews that they may not grow feeble, but our spiritual organs, which were made to act for an entire lifetime, remain unused, undeveloped, and so, with the passing years, they lose their vitality. Yet our spiritual like our bodily health depends upon the regular functioning of these organs. Unconsciously we feel how a hearty laugh liberates us, how a good cry or an outbreak of anger relieves us We have an absolute need of emotion and its expression

Against this our upbringing constantly works. Its first commandment is: "Hide what goes on within you Never let it be seen that you are stirred up, that you are hungry or thirsty; every grief, every joy, every rage, all that is fundamental and craves utterance, must be repressed." Hence the well-known sublimations, the hysterical tendencies of the time, and finally that empty play-acting of which modern life is full Passion, bursts of feeling and fancy, are ruled outside the bounds In their place we have set up in a row common stereotyped forms of expression that are part of our social armour. This armour is so rigid and constricted that there is hardly any room for natural action. We cultivate a few useful expressions of interest, of pleasure, of dignity, and a set grimace of politeness We ask people how they feel without waiting for an answer or, in any case, without paying attention to it With a fixed intonation, which could be written down and reproduced wholesale, we say that we are happy to see them, though the encounter may be a matter of complete indifference to us when it is not actually fatal At weddings, christenings, burials, festivities we make out of hand-shaking and bowing, out of frowns and grins, a ghostly play, in which the absence of feeling is shocking.

The modern social code has crippled the actor, whose business it is to body forth feeling When generations have been brought up to repress the emotions, nothing in the end remains either to inhibit or to show. How can the actor, rooted deep in the bourgeois existence of every-day, suddenly in the evening leap into the life of the mad king, whose unrestrained passion sweeps like a storm across the moors? How shall he make it credible that he is killing himself through love, or that he has killed another through jealousy? It is significant that our modern theatre can hardly boast a true lover When the actor on the stage says "I love you," it is the custom in many theatres to resort to musical accompaniment of the wood instruments, in order to evoke a poetical atmosphere The soul is set vibrating by a *vibrato* of the violins—otherwise one could scarcely distinguish an "I-love-you" from a "How-do-you-do." Generally, the women are more impulsive because they still live closer to nature than men.

In former times, when actors were excluded from bourgeois society and wandered about like gypsies, they undoubtedly developed stronger, rarer personalities. They were more unbridled in their passions; their outbursts were more powerful, the spirits that possessed them, more masterful. They had no outside interests They were actors, body and soul To-day the body is willing, but the spirit is weak, and their interests are divided.

Of course, all these observations and all rules fail before the wonder of genius But there is little genius, and there are many theatres. Now, to every person nature gives a face of his own.

There is as small chance of finding two men who exactly resemble each other as of finding two leaves on a tree which are precisely alike. Yet in the narrow course of bourgeois life, driven hither and thither by the current of every-day, they are in time worn down until they become like round pebbles One individual looks like another. This grinding process also has its effect upon their psychological make-up. But the highest boon of mankind is personality. In the arts, personality is the decisive factor; it is the living kernel which we seek in every artistic work.

Bourgeois standards should not be applied to artists, for what is it that distinguishes the artist? It is that he reacts to whatever he encounters deeply and powerfully; that things hardly visible, hardly audible, stir and move him, that he is driven by an irresistible impulsion to give all that he experiences back again, realized in some form of expression It would be a gross injustice to wish to profit by these gifts in the arts, and yet in life outside to condemn them.

The art of acting originated in the earliest childhood of the race Man, allotted a brief existence, in a close-pressing crowd of various kinds of individuals, who were so near him and yet so elusively far, had an irresistible desire to throw himself into a fantastic play of changing one form into another, one fate into another, one effect into another These were the first attempts to fly above his narrow material existence The possibilities inherent in him but not brought to full growth by his life thus unfolded their shadowy wings and carried him far over his knowledge and away into the heart of a strange experience. He discovered all the delights of transformation, all the ecstasy of passion, all the illusive life of dreams

Made as we are in God's image, we have in us something of the godlike creative will Therefore we create the whole world over again in the arts, with all the elements, and on the first day of creation, as the crown of our work, we make men in *our* image

Shakespeare is the greatest, the one truly incomparable boon that the theatre has had He was poet, actor, and producer in one. He painted landscapes and fashioned architectural scenes with his words. In his plays everything is bathed in music and flows into the dance. He stands nearest to the Creator It is a wonderful full-rounded world that he made—the earth with all its flowers, the sea with all its storms, the light of the sun, the moon, the stars; fire with all its terrors and the air with all its spirits—and in between, human beings with all their passions, their humour and tragedy, beings of elemental grandeur and, at the same time, utter truth His omnipotence is infinite. He was Hamlet, King Claudius, Ophelia, and Polonius in one person Othello and Iago, Brutus and Cassius, Romeo and Juliet, Falstaff and Prince Henry, Shylock and Antonio, Bottom and Titania, and the whole line of merry and sorrowful fools lived within him He engendered them and brought them to birth; they were part of his inscrutable being Over them he hovers like a godhead, invisible and intangible Nothing of him is there but this great world. Yet in it he is ever present and mighty. He lives eternally

Only that art is living, in whose inmost chamber the human heart beats

For the moment the theatre is, we realize, threatened; it is in a decline to-day because in the noise and rush of the great cities, though material means of existence are given it, its peculiar festal beauty, the enchanted sense of play, has been taken from it. It has not yet been organically co-ordinated with the sudden growth of the modern metropolis

The arts, especially the theatre, forsaken by the good spirits, can be the sorriest business, the poorest prostitution—there is its pale first cousin, the film, which was born in the city and has undoubtedly flourished better there. But the passion to act in the theatre, to go to the theatre, is an elemental desire in mankind. It will always draw actors and spectators together to the play, and out of that dionysian union in which they rise above the earth, it will produce the highest art that alone brings felicity.

The theatre is deathless. It is the happiest loophole of escape for those who have secretly put their childhood in their pockets and have gone off with it to play to the end of their days. The art of the stage affords also liberation from the conventional drama of life, for it is not dissimulation that is the business of the play but revelation. Only the actor who cannot lie, who is himself undisguised, and who profoundly unlocks his heart deserves the laurel The supreme goal of the theatre is truth, not the outward, naturalistic truth of every-day, but the ultimate truth of the soul.

We can telegraph and telephone and wire pictures across the ocean; we can fly over it. But the way to the human being next us is still as far as to the stars The actor takes us on this way. With the light of the poet he climbs the unexplored peaks of the human soul, his own soul, in order to transform it secretly there and to return with his hands, eyes, and voice full of wonders.

He is at once sculptor and sculpture, he is man at the farthest borderline between reality and dream, and he stands with both feet in both realms The actor's power of self-suggestion is so great that he can bring about in his body not only inner and psychological but even outer and physical changes. And when one ponders on the miracle of Konnersreuth, whereby a simple peasant girl experiences every Friday the Passion of Christ, with so strong an imaginative power that her hands and feet show wounds and she actually weeps tears of blood, one may judge to what wonders and to what a mysterious world the art of acting may lead; for it is assuredly by the same process that the player, in Shakespeare's words, changes utterly his accustomed visage, his aspect and carriage, his whole being, and can weep for Hecuba and make others weep Every night the actor bears the stigmata, which his imagination inflicts upon him, and bleeds from a thousand wounds. (M RE)

THEORY OF MODERN PRODUCTION

The theatre at any period in history has always provided an immediate reflection of the life of that period, and accordingly, we find in the theatre of to-day splendour, speed, luxury and an eager reaching out in every direction for new ways in which to seize and to communicate every phase of modern life. A brief glance at the illustrations, shown herewith, which are chosen from the designs of artists whose work is characteristic of the theatre of our time, will confirm this statement. Life is moving and changing and the theatre is moving and changing very swiftly with it. We are living in a period of high nervous vitality, of discontent, of restless experimentation, of feverish search for new ideals and new standards.

In the midst of this incessant activity it is difficult to indicate any one precise direction in which the theatre is moving at the present time or to prophesy the forms it may assume even in the near future A decade hence the theatre of 1929 may come to be regarded as incredibly crude, naive and amorphous. But it is suggested that at this moment we have at our disposal a new and hitherto undeveloped medium of dramatic expression which during the next few years may profoundly change modern theatrical production. This medium is the talking picture.

Modern psychology has made us all familiar with the idea of the subconscious. We have learned that just beneath the surface of our everyday normal conscious existence there lies a vast region of dreams, a hinterland of energy which has a form of its own and laws of its own, laws that motivate our inmost thoughts and actions This conception has profoundly influenced the intellectual life of our day It has already become a commonplace of our thinking, and it is beginning to find expression in our art. Writers like James Joyce, painters like Matisse and Picasso, musicians like Debussy and Stravinsky, have ventured into the realm of the subjective and have recorded the results of their explorations in all sorts of new and arresting forms. Our playwrights, too, have begun to explore this land of dreams In two dramas recently produced in New York, Eugene O'Neill's *Strange Interlude* and Sophie Treadwell's *Machinal*, an attempt has been made to express directly to the audience the unspoken thoughts of the characters, to show us not only their conscious behaviour but the actual pattern of their subconscious lives. These adventures into the subjective indicate a trend in dramatic writing which is bound to become more general as the laws of the subconscious become more and more clearly understood It seems strange, strik-

ing, that just at this moment in the world's history there has come into existence the talking picture, a perfect instrument for expressing the subconscious in theatrical productions. *In the simultaneous use of the living actor and the talking picture in the theatre there lies a wholly new theatrical art, an art whose possibilities are as infinite as those of speech itself*

The dramatists of to-day are casting about for ways in which to express the workings of the subconscious, to express thought before it becomes articulate. They have not seen that the moving and talking picture is itself a direct expression of thought before thought becomes articulate They are trying to give us in the theatre not only the outward actuality of our lives, but the inward reality of our thoughts They are seeking to go beyond the everyday life we normally know into the never-ending stream of images which has its source in the depths of the self, in the unknown springs of our being But in their search for ways in which to express their new awareness of life, they have not observed that the moving picture is thought made visible.

This statement is in itself a revolutionary one, but it is true The moving picture runs in a stream of images, just as our thoughts do, and the speed of the moving picture, with its "flash-backs" and abrupt transitions from subject to subject, is very close to the speed of our thoughts Here lies the potential dramatic importance of this new invention The dramatist has it in his power to enhance and elaborate the characters of his drama to an infinite extent by means of these moving and speaking images Some new playwright will presently set a motion picture screen on the stage above and behind his living actors and will reveal the two worlds that together make up the world we live in—the outer world and the inner world, the world of actuality and the world of dream *Strange Interlude, Machinal* and the "talkies" have shown us the way toward this new drama Within the next decade a new dimension may be added to our theatre.

(R E J.)

CHINESE THEATRE

The Chinese drama, as it had existed from ancient times up to the time of the Revolution in 1911, was a continuous development from simple primitive forms to a very complex and elaborate one. (*See* DRAMA, CHINESE) Such evidence as can be found in the Chinese classics makes it certain that the origins were in ancestor worship and religious dancing, and in the acrobats and clowns who entertained the courts, presenting an obvious analogy to the drama of the middle ages Added to this, we have the evidence of the engraved reliefs of the Wu tombs and of such stelae as that in the Boston museum (dated A D 529) Also the numerous grave figurines which present a variety of actors and dancers, giving visual proof of the type of dancing engaged in in the Six Dynasties and the T'ang dynasty Traditionally, the acting of stories is attributed to the Han dynasty References are made to stories accompanied by song and dance in the North Ch'i dynasty. The use of animal and demon masks was probably primitive and early, but legend ascribes the origin of the terrifying warrior masks to the prince of Lan Ling who had a face so beautiful that he had to invent a "false face" of carved wood in order to frighten the enemy. Whatever the truth of the matter, the Chinese have developed painted faces which are the equivalent of the Japanese Nō masks (*See* MASKS)

In the T'ang dynasty the Emperor Ming Huang was famous as a patron of the arts of drama and dancing He established the "Pear Garden," a court institute of music, dancing and acting, and established a similar institute for the training of females, a reference which seems to indicate that the 19th century tradition of the segregation of sexes in dramatic companies was an old and persistent one.

Development.—The Chinese speak of three epochs in the development of the drama. (1) from the reign of Ming Huang (A D 720) to the fall of the T'ang dynasty; (2) from the beginning of the Sung dynasty up to the close of the reign of Hui Tsung, a great patron of all the arts; (3) from and including the reign of the Golden Tatars of North China and the whole Yüan (Mongol) dynasty. This classification seems to be purely arbitrary and the real puzzle to the historian of Chinese drama lies in the question of the Mongol drama. All the proper pre-Yüan dramatic literature is lost; the theory is that Chinese littérateurs under a barbarian rule turned their genius to an art which they considered inferior. This they did partly as a matter of politics, partly for diversion and partly out of contempt.

From this period the names of plays and dramatists are preserved. (Among the dramatists were Wang Shih-fu, 王實甫 Shih Chün-mei, 施君美, Kuan Han-shêng, 關漢聲, Ma Chih-yüan, 馬致遠, and Ch'iao Lifu, 喬立符.) Sure as it seems that the drama as serious literature was at its height during this period, the question of how much of the theatre of that period was an innovation and how much was the elaboration of straight tradition is a completely open one The opinion of the author is that the tradition, however tricked out, was not changed. Dancers of the 20th century move from posture to posture which are identical with those of the T'ang dynasty grave figurines and there are many analogies to the Nō drama of Japan which have never been properly looked into, notably similar conventions, and, in the male characters, a similar use of intoned chanting (*See* NŌ DRAMA.)

The drama continued to flourish under the Ming dynasty and apparently did not give way to a new form until the middle of the Ch'ing period when an easier and more popular style became the mode. The classical drama, or *k'un ch'u*, 崑曲 has persisted to the present day but is largely kept up by scholarly amateur societies. There are a few great professional singers of the classical drama, and the great popular actors usually include a few classical rôles in their repertoires, but for the most part dramatic performances are in the popular (*êrh huang*) 二黃 mode developed under the Manchus In the third decade of the 20th century the modernists were attacking the stage tradition with everything else that has been great in China and have fallen into weak imitation of the western dramatic forms, so far with very little effect on the old theatre except that the fashionable actors are deserting the traditional type of stage and are taking to western stages, painted scenery and spotlights.

Forms of Entertainment.—The Chinese employ a form of entertainment for which we have no single word. It is a combination of spoken dialogue, operatic singing and ballet dancing Both the theatre and the performance present immediate analogies to the Elizabethan drama The theatre, except for refinement of decoration, is almost identical in arrangement, but the Chinese theatre always has a roof except in the case of temple theatres which consist only of the actual stage itself Like the Elizabethan theatre, the Chinese use only the scantiest stage properties an embroidered curtain at the rear with entrances left and right, furniture carried in and out during the performance, landscapes indicated by symbolic plaques. The imperial theatres went further and had contraptions which resemble those described in writings of the Italian Renaissance, including balconies, pits in the floors and holes in the ceilings through which actors could be lowered Further analogies with the Elizabethan theatre appear in the long monologues which the actor addresses to an audience in a fully lighted house, and monologues so presented become logical and exciting confidences and not at all the dull and abstract versions which westerners present in Elizabethan revivals Furthermore, the actors are all of one sex, usually males, and the perfection of female representation teaches the westerner what such representation must have been in England. Another analogy is in the comic interludes of exaggerated clowning, as yet happily unexpurgated

But the Chinese have developed a whole set of conventions which are apparently incomprehensible to Western nations Not only are the gestures and movements of the different sexes and ages represented bound by conventions, but the very voices themselves must conform to similar conventions The typical classification of parts is as follows. The *tan* (旦, Mongol colloquialism for "woman"), or young female, moves in a set, rhythmical sway and speaks and sings in a high falsetto. The clothes for these parts are designed and built in long flowing lines to increase the impression of flower-like grace; the make-up is elaborated red and white. The *lao tan* (老旦, *lao,* old; *tan,* see above), or old lady, walks in four-four time with a slight palsied shake; she bends a little but does not sway, wears no make-up and usually wears a

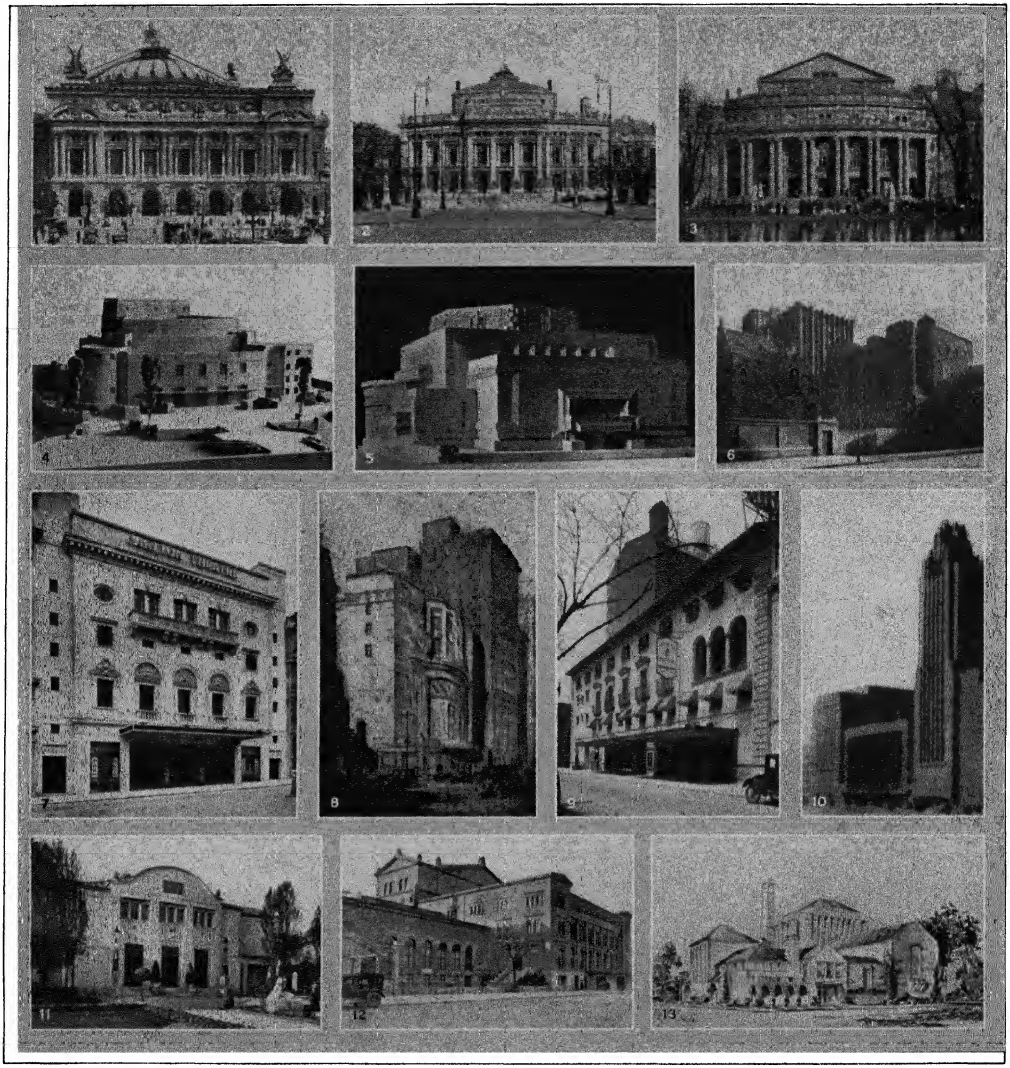
INTERIOR OF MODERN THEATRES

1, 3. The Capitol Theatre, Berlin, a German motion picture house, illustrative of the simple expression prevalent in contemporary German design. Changing light and colour on broad surfaces contribute most of the decorative effect. Architect, Hans Poelzig. 2. Titania Palace, Berlin, a motion picture house in which the successive elliptic arches of the proscenium and the modern lighting form the chief decorative feature. The seating arrangement, with a centre aisle, is contrary to the usual German manner. Architect, Stegnitz. 4. Roxy Theatre, New York city, a motion picture theatre with a seating capacity of 6,100, at the time of its construction the largest in the world. The Plateresque decoration follows the over-ornate fashion popular in American film houses. Architect, Walter Alschlager. 5. Proscenium of a projected opera house for New York city. The introduction of the side stages behind open colonnades provides for the spectacular pageantry of traditional opera and affords direct control of the choruses and stage music by a single conductor. The psychological effect of close contact between audience and performers of the classic theatre is also achieved by this means. Architect, Joseph Urban. 6. Model of Oskar Strnad's projected theatre, showing the auditorium as seen from one segment of the stage which is a doughnut-shaped, movable ring surrounding the auditorium. 7. The Allen Theatre, Cleveland, O., a motion picture theatre without a stage. Architect, C. Howard Crane. 8. The Künstler Theatre, Munich. The floor slants steeply and the seating arrangement is that commonly used in Germany, each row forming an aisle leading to side walls with many doors. Architect, Max Littmann.

THEATRE ARCHITECTURE



BY COURTESY OF (2) THE AUSTRIAN TOURIST OFFICE, (3, 12) THE GERMAN RAILROADS INFORMATION OFFICE, (7) "THE BUILDER," (11) MAX LITTMANN; PHOTOGRAPHS, (1) EWING GALLOWAY, (4) E. N. A., (6) GENERAL PHOTOGRAPHIC AGENCY

EXTERIORS OF 19TH AND 20TH CENTURY THEATRE BUILDINGS

1. The Opera House, Paris, erected 1861–75, in the court style of the period of Louis Napoleon. Architect, Charles Garnier. 2. The Burgtheater, Vienna, an elaborate structure of classic 19th century type, housing the outstanding repertory company of central Europe. Architects, Semper and Hasenauer. 3. View of the State Theatre, Stuttgart, showing the façade of the larger of the two auditoriums contained in the single unit building which fronts the lake in the park. Architect, Max Littmann. 4. Model of the prize-winning design for the Shakespeare Memorial Theatre, Stratford-on-Avon, England. Architect, Elizabeth Scott. 5. A project for a theatre by Frank Lloyd Wright, pioneer among modern American architects. He conventionalizes very frankly the exterior expression of the inner divisions of the house. 6. Back view of the Schauspielhaus, Düsseldorf, Germany, erected 1904–05. Architect, B. Sehring. 7. The Carlton Theatre, London, an exterior designed in a prevailing British mode, and crowded between neighbouring houses, like most American and British commercial theatres. 8. The Ziegfield Theatre, New York city, a musical comedy house, frankly theatrical in treatment, with the proscenium symbolized in the massive curve of the lower part of the façade. Architect, Joseph Urban. 9. The Guild Theatre, New York city, housing the offices and club rooms of the Theatre Guild, as well as its stage and auditorium. The stage house continues the period of the façade. Architect, C. Howard Crane. 10. Projected opera house and studio building for New York city, designed to harmonize a large theatre with the prevailing skyscraper architecture of New York. Architect, Joseph Urban. 11. Künstler Theater, Munich, a simple and thoroughly modern façade designed before the war for a theatre in an exposition park. Architect, Max Littmann. 12. The Kroll Opera House, Berlin, a severe design in keeping with the conventional architecture of Berlin, yet not too much at variance with its modernist interior. Architect, Oskar Kaufmann. 13. The Play House, Cleveland, O., one of the "little theatres" of America, containing two auditoriums, one seating 500, the other 200, along with workshops, offices, etc. Architects, Philip Small and Charles Bacon Rowley

bright orange bandeau to increase the effect of pallor. She speaks and sings in a falsetto The *hsiao shêng* (小生, young man) moves in a measured and animated stride. His make-up is slight, confined to pink-and-white cheeks and exaggerated eyebrows. He speaks and sings in falsetto and may, in speaking, change his range from falsetto to a natural tenor The cut of his costume is simple and sculpturesque, a long loose robe in which he moves easily. The *lao shêng* (老生, old man) uses movements and gestures the same as the young man's but with less buoyancy. He usually speaks and sings in falsetto but may talk in a sustained tenor His clothes are of the same cut as the young man's but differ in details of head-dress and are less gay in colour The *hua lien* (花臉, painted face) represents the warrior. With the exception of very young warriors, who wear neither painted faces nor beards, all actors representing warriors are made up with elaborately painted faces in bright colours and striking designs appropriate to the contours of the human face These painted faces are the equivalents of masks. The warrior moves in an exaggerated strut and speaks in a deep throaty roar He sings variously, according to part and actor, ordinarily in a forced bass but occasionally in a piercing tenor. His clothes are built to give the impression of force and strength and include elaborate underpads for the torso and shoulders, heavily embroidered epaulettes and stomachers and long scalloped panniers which flare as he moves. He wears enormous head-dresses, often with 6 ft pheasant feathers and sometimes four pennants attached to his back. The *ch'ou* (丑 *ch'ou*, is the second of the 12 zodiac signs but has come to be applied to the comedian or clown, probably because it is homonymous with *ch'ou*, 醜, meaning homely), or comedian, is allowed more liberty of voice and action, the result being close to our exaggerated clown parts He is almost always distinguished by white circles around the eyes

These are the main distinctions. The conventions are carried much further into the special representation of definite characters in which not only the exact make-up for that particular character is prescribed but even the colours used carry symbolic meanings The costumes themselves are far more subtle and complicated than those of the Nō drama of Japan, the obvious beauty of which is apparent to the dullest eye The Chinese costumes, like the Japanese Nō costumes, are in a style which might well be described as architectonic The actor is considered a kind of puppet on which the designer builds up a character of whatever sex and of whatever physique he chooses The outlines of the figures are always clearly defined but the surface of a given mask is often covered with intricate patterns, which makes an ensemble of Chinese actors a more complicated picture than an ensemble of the Nō actors The subject matter of the plays is almost always traditional It includes stories from famous novels, anecdotes and legends about historic personages, stories of the "Three Kingdoms," in content suggestive of the Morte d'Arthur legend, and satiric burlesques of the church and of historic villains.

Kinds of Drama in China.—The classical drama or *k'un ch'ü* (崑曲) takes its name from the K'un Shan district in the present province of Kiangsu It is a highly refined and perfected form in which every gesture is in prescribed concordance with words and music, but the gestures and, to a certain degree, the emphasis of the singing is not written down but is handed down from teacher to teacher The music itself includes an infinite number of tunes, each composed for a particular drama. The instruments include wind instruments (a kind of flute and oboe, and the *shêng*, 笙, a mouth organ made of 17 small bamboo pipes), trumpets, drums, bells and plucked string instruments Stringed instruments played with a bow are never used in the *k'un ch'ü*.

The popular drama which has several different names, most of which bear a geographical significance, is best referred to as *erh huang* (二黃) and *p'i huang* (皮黃), because it originated at Huang Kang and Huang P'i, two districts in the province of Hupei. It is sometimes known as *han tiao* (漢調) from the river Han which flows through the region. It is also called *ching tiao* (京調), a southern name given to it after it had become the popular form in Peking, the capital. It is a much more flexible and careless form than the classical form. Tunes are less varied and are often used for a number of different plays, and the tunes have far less quality than those of the classical drama. The accompaniment includes largely stringed instruments played with a bow, wind instruments (exclusive of the *shêng* which is not used), drums, gongs and cymbals The action is far less highly developed A third kind of theatrical entertainment is known as the *shansi pang tzŭ* (山西梆子) or *pang tzŭ ch'iang* (梆子腔), a rustic form of drama introduced from the province of Shansi, the outstanding characteristic of which is the persistent use of the trumpet and a kind of rattle known as *pang tzŭ* (梆子).

THÉÂTRE DE LA MONNAIE: *see* OPERA HOUSES, FAMOUS.

THEATRES, LAW RELATING TO. Playhouses grew up in England after the Renaissance, when the religious drama began to give place to the secular drama Apparently, licences for temporary theatres were first granted in the reign of Henry VIII.; but as the number of regular playhouses increased, letters patent to perform stage plays were granted to Burbage, Shakespeare and others by Elizabeth and James I. By an Order in Council passed in 1600, the number of playhouses in London was limited to two; one in Middlesex and one in Surrey, but this restriction was not strictly enforced. The theatres continued to function independently of legal control until 1647, when an Ordinance of the Roundhead Government closed all playhouses and even inflicted penalties on any spectator at stage plays With the Restoration, the theatres were re-established, and royal patents granted to Killigrew and Davenant, in 1662, for their theatres in Drury lane and Covent garden, the one enjoying the official patronage of Charles II, the other the patronage of the duke of York

The Theatres Act of 1737 (10 Geo. II *c.* 28) instituted statutory control over playhouses, the plays and players which continued for more than a century The act provided (*inter alia*) that no person should be authorized either by letters patent or by licence to perform stage plays anywhere in Great Britain except within the City of Westminster or the liberties thereof, or in places of royal residence during the period of such residence This limitation was subsequently modified by an act passed in 1788 (28 Geo III. *c* 30) The acting of plays at the universities (which had been privileged places originally) was forbidden by 10 Geo. II. *c.* 19.

Walpole's act of 1737 consolidated the position of the patent theatres, and in spite of a long and bitter struggle between the patent theatres and the non-patent theatres, the former maintained a virtual monopoly down to 1843, when the recommendations of the parliamentary committee of 1832 were put into effect by the passing of the Theatres Act, 1843 (6 and 7 Vict *c.* 68), which freed the London stage, and established legal control over playhouses as it exists to-day.

All theatres, music-halls and other places of public entertainment in Great Britain, must be licensed for the purpose for which they are intended to be used No theatre licence is required if the performances are not public (see *Harms* v *Martans Club*, 1926, 1 ch 870); or if the plays presented are not stage plays within the meaning of the act (for meaning of stage plays, *see* below); or if the premises are not of a permanent character (*e.g.*, a portable booth); or if the theatre is licensed by letters patent; or if the performance is given in any booth or show at a fair or other customary feast.

Theatre licences are granted by the lord chamberlain for all theatres within the parliamentary boundaries of the cities of London and Westminster, and of the boroughs of Finsbury and Marylebone, etc. For theatres situate elsewhere, the county councils are the proper licensing authority; but they may delegate

their powers to committees or to justices of the peace. Licences can only be granted to the responsible manager for the time being of the theatre in question, who must enter into a bond for a sum not exceeding £100 The fee for a licence is 10s. per calendar month in the case of the lord chamberlain's licence, and 5s. per calendar month for a licence granted by any other authority. All licensing authorities are empowered by the Theatres Act to make rules and regulations for maintaining order and decency in theatres licensed by them; and for ordering the closing of any theatre and suspending its licence where any riot or misbehaviour takes place (ss 8 and 9).

Music and Dancing Licences.—Music-halls and similar places of entertainment were first brought under legal control by the Disorderly Houses Act, 1751, which is still in force. A licence is required for any house, room, garden or other place kept for public dancing, music, or other such public entertainment.

The conditions under which music and dancing licences are granted vary according to the area in which the premises to be licensed are situate The London County Council deals with all licensing within the administrative county of London. Premises situate within the administrative county of Middlesex are governed by the Music and Dancing Licences (Middlesex) Act, 1894; and certain portions of the home counties (Buckinghamshire, Essex, Hertford, Kent, etc), are now governed by the Home Counties (Music and Dancing) Licensing Act, 1926 Outside these areas, either part IV of the Public Health Act, 1890, applies, or the licensing of music and dancing is provided for by local acts. In London, Middlesex and the home counties, licences are granted by the county councils, and elsewhere by the licensing justices, to such persons as they think fit, for any specified period up to one year Except in the case of licences granted by the London County Council, it is made a condition of every licence that an inscription must be affixed to licensed premises stating that they are licensed pursuant to the act of parliament, and that such premises may only be kept open during specified hours A licence which is granted only for music does not authorize public dancing and vice versa (*Brown* v *Nugent*, 1872, L R. 7, Q B. 588).

Neither a theatre licence nor a music and dancing licence is required in the case of an army or navy recreation room which is managed or conducted under the authority of a secretary of State or the Admiralty A theatre licence does not dispense with the necessity of holding a licence for music or dancing, and vice versa Licensing authorities have a discretion to refuse a theatre or music and dancing licence or to grant it only subject to such conditions as they think fit to impose; but they must act reasonably (*Reg.* v. *West Riding County Council*, 1896, 2 Q B 386)

Censorship and Legal Control of Stage Plays.—An Ordinance was published by James I. forbidding the representation of any living Christian king upon the stage. This was occasioned by the appearance of players in the character of the king of Spain and Gondomar; and it foreshadows part of the present policy of the censorship The control of stage plays was originally vested in and exercised by the master of the revels, whose office had been traced back to the year 1545 The supervision of stage plays was also carried out by the Privy Council, the Star Chamber and the lord chamberlain; but records show that about the year 1624 the lord chamberlain became the principal authority over these matters The lord chamberlain continued to control stage plays, deriving his authority from the royal prerogative until Walpole's act in 1737 gave statutory recognition to his censorship by enacting (ss 3 and 4) that all new plays must be submitted to the lord chamberlain for approval. He, in turn, named an examiner of plays to assist him. The stage censorship thus constituted was continued by the Theatres Act, 1843

Stage plays produced anywhere in Great Britain are now under the absolute control of the lord chamberlain of His Majesty's household. Under the Theatres Act, 1843, the lord chamberlain is empowered:—(*a*) to license every new stage play or any new addition to an old stage play or to an old prologue or epilogue which is intended to be produced and acted for hire in any theatre in Great Britain (s 12); (*b*) to control all stage plays, whether new or old, by forbidding them to be acted or presented if he is of opinion that it is fitting for the preservation of good manners, decorum, or of the public peace to do so (s. 14).

The lord chamberlain's "Regulations for the Submission of Stage Plays" set out the procedure to be observed in applying for a licence to perform a stage play, and the fees to be paid for the licences required (*See* also Theatres Act, s. 13.) A licence is only required if the performance is to be given "for hire" in a theatre; and a performance is only deemed to be given "for hire" if any money or other consideration is taken, directly or indirectly, for admission to the performance, or if it takes place in any house, room, etc , in which distilled or fermented excisable liquor is sold (s. 16). The lord chamberlain's regulations lay down some of the grounds on which the lord chamberlain may intervene to prohibit the performance or refuse a licence. As to penalties, *see* Theatres Act, s. 15, as amended by the Criminal Justice Act, 1925 (s. 43)

Days and Times of Performances.—The Sunday Observance Act, 1781, prohibits the opening on Sundays of any premises for public entertainment or amusement, to which the public are admitted by the payment of money or by tickets sold for money. The act does not apply to religious meetings, or to any entertainment to which persons are admitted without payment. Licences frequently contain a condition that performances shall not take place on certain specified days, and sec. 8 of the Theatres Act, 1843, empowers the lord chamberlain to order any patent theatre or theatres licensed by him to be closed on such public occasions.

Theatres under the jurisdiction of the lord chamberlain are not under any restrictions as to the hours for performances, but other licensing authorities may make rules regulating the times during which the theatre within their jurisdiction may be opened (s. 9 of Theatres Act, 1843). Premises licensed for music and dancing, etc , may only be opened for those purposes between noon and midnight, but the Licensing Statutes provide for these hours being extended on special occasions if permission is first obtained from the licensing authority

There are a number of statutory provisions relating to the construction and safety of theatres and other buildings used for public entertainments, the chief of which are to be found in the Metropolis Management Act, 1878, and the Public Health Act, 1875, sec. 158.

The Common Law Affecting Theatres, etc.—At common law the admission of the public to theatrical, etc., performances is in the discretion of the management, but once the right of admission is granted, it cannot be withdrawn except under certain circumstances. The legal position of the ordinary ticket-holder is that he has the irrevocable right to be admitted to see an entertainment until its close, provided that he behaves properly (*Hurst* v. *Picture Theatres Ltd* , 1915, 1 K B. 1), and that he has not obtained admission by fraud or by the concealment of identity (*Said* v. *Butt*, 1920, 3 K B 497). The purchase of a ticket for a performance carries an implied warranty by the management that the premises shall be reasonably safe; but this warranty does not extend to any unseen and unknown defects which could not be discovered by ordinary inspection (*Francis* v. *Cockrell*, 1870, L.R 5, Q B. 184, 501; *see* also NEGLIGENCE)

The management is also responsible for the safety of the performance itself; and they will be liable for injury caused to the audience by the negligence of any actor or other performer who is their servant or agent If, however, the actor is not the servant of the management but of another person (*e g* , a touring manager) who is presenting the play or entertainment under a contract with the management of the theatre, the latter will only be liable if the performance is intrinsically dangerous, or if they fail to take reasonable steps to ensure that any dangerous incidents are performed without risk to the playgoer (*Cox* v *Coulson*, 1916, 2 K.B. 177; *see* also NUISANCE).

Theatrical Performers and the Law.—The legal position of theatrical performers is now governed by (*a*) the common law of contract; (*b*) theatrical custom; and (*c*) special legislation.

(*a*) At common law an actor or other theatrical performer is regarded as being in a different position from that of the ordinary servant or employee Thus he is entitled to be given the oppor-

tunity of performing and of gaining the publicity which is an essential part of the consideration of the contract of performance (*Marbe* v. *George Edwardes* [*Daly's Theatre*], *Ltd.*, 1928, 1 K.B. 269). He may refuse a part which is unsuitable for him (*Clayton-Greene* v. *De Courville*, 1920, 36 T.L.R. 790); and may decline to play a part at unreasonably short notice (*Graddon* v. *Price*, 1827, 2 C. and P. 610). The tendency of recent years has been to standardize theatrical contracts. The standard form of contract for engagements of variety artists is the "Award" contract, evolved as the result of the arbitrations held in 1913 and 1919 to settle disputes between members of the variety profession and their employers. The "Valentine" form of contract is largely (but not universally) used for London (West End) engagements of actors and actresses. A contract to perform on premises which are not licensed, or in a play which has not been approved by the lord chamberlain will be void for illegality (*Galline* v. *Laborie*, 1793, 5 T.R. 242; *Gray* v. *The Oxford* [*Ltd.*], 1906, 22 T.L.R. 684, etc.). Similarly the presence of a "barring" clause (a form of restrictive covenant which prevents a performer from performing elsewhere within a certain area and within a specified time of the particular engagement) may vitiate the contract as being in restraint of trade, if its terms are too wide or unreasonable (*Tivoli* [*Manchester*] *Ltd.* v *Colley*, 1904, 20 T.L.R 436). A term in a contract restricting an actor from using his stage name has been held to be void (*Hepworth Manufacturing Co.* v. *Ryott*, 1920, 1 Ch 1).

Outside the law of contract, a theatrical employee is in practically the same position as the ordinary employee. The management is liable for negligent or tortious acts committed by him in the course of his employment (*e g*, an infringement of copyright; see *Performing Right Society, Ltd.* v *Mitchell, etc.*, 1924, 1 K B. 762). The management is also liable for the personal safety of the performers, unless the injury is occasioned by the negligent or wrongful act of a fellow performer or fellow employee, *e g.*, a scene shifter (see *Burr* v. *Theatre Royal, Drury Lane, Ltd.*, 1907, 1 K B 544).

The Employer's Liability Act, 1880, does not appear to apply to an actor or similar performer; but might apply to other classes of theatrical employees The Workmen's Compensation Acts have been held to apply to various classes of theatrical employees.

(*b*). The customs of the theatrical profession will govern contractual and other legal relations between performers and management, providing they fulfil the usual legal requirements as to custom The following theatrical customs have been upheld by the courts: That an engagement to perform in a play in the West End of London is for the run of the piece (*George Edwardes* [*Daly's Theatre*] *Ltd.* v *Comber*, 1926, 42 T L R. 247); that an engagement to perform elsewhere for an indefinite period may be terminated by either side giving two weeks' notice; that, in an engagement for one or more years, no payment of salary is payable during vacation when the theatre is closed (*Grant* v. *Maddox*, 1846, 15 M. and W. 737); that a manager who engages a theatrical company to perform for one week must not allow another company to perform at that theatre during the same week, either by means of a "flying matinee" or otherwise (*Cotton* v. *Sounes*, 1902, 18 T.L.R. 456); that a variety or music-hall artist shall be advertised in a manner suitable to his professional reputation.

(*c*). During recent years a great deal of legislation has been passed, with the object of protecting theatrical performers The Theatrical Employers Registration Act, 1925 (which was intended to protect theatrical performers against unreliable and unscrupulous managers), requires every person who employs at one time three or more theatrical performers, to be registered in accordance with the procedure laid down by the Act The Act also makes it an offence for theatrical employers to abandon the performers during the course of an engagement, and imposes penalties on persons who carry on business as theatrical employers without being registered, or who procure registration by supplying misleading information, etc. Furthermore, a theatrical employer may be struck off the register if he is shown to have attempted to evade payment of his employees. Theatrical agents who carry on (within the administrative county of London) the business of teaching or of finding employment for those desirous of obtaining employment as singers, dancers, etc., at theatres or in connection with film production, must be licensed for the purpose by the London County Council or by the City Corporation (*see* the London County Council (General Powers) Act, 1921, ss. 11, 14). The Performing Animals (Regulation) Act, 1925, provides for the registration of performing animals and for inspection of them by duly authorized officers, so as to ensure that their training and exhibition is not accompanied by cruelty A whole group of recent enactments protect children who are employed in theatrical, etc , performances The Children's Dangerous Performances Act, 1879 (as amended by the Dangerous Performances Act, 1897), makes it an offence to cause any male person under the age of 16 years, or any female person under the age of 18 years, to take part in any public performance or exhibition which is dangerous to life or limb The parent or guardian who aids or abets such an offence is liable to a penalty; and if any actual injury is sustained, the employer may be indicted for assault and ordered to pay compensation not exceeding £20

The Children (Employment Abroad) Act, 1913, makes it necessary for a licence to be obtained from a police magistrate to enable any young person under the age of 16 to go out of the United Kingdom for the purpose of singing, playing, performing or being exhibited for profit This licence will only be granted upon the conditions prescribed by the act, which include supervision by consular officers The Education Act, 1921 (s. 100), limits the hours during which children may be employed in public, theatrical, etc , performances, and also imposes certain restrictions on the training of young persons as acrobats or contortionists. These restrictions may, in certain cases, be relaxed by local education authorities or by courts of petty session But apparently, no child under the age of 12 years may be employed at *any* time on any public premises to which the public are admitted on payment

The Dramatic and Musical Performers Protection Act, 1925, prohibits the reproduction of the performances of actors, singers, etc , by mechanical means for the purposes of trade without their written consent. (S C. I)

United States.—In the United States questions of licensing theatres involve statutes in 48 States Where the licensing power has been delegated to the municipalities, ordinances in the various cities are likewise involved "Little Theatres," springing up in great numbers throughout the United States, ordinarily avoid requirements of a licence (as well as building regulations) by organizing as a club whose members subscribe for tickets

Although a theatre is a private enterprise (*Tyson and Brother* v *Banton* [1927], 273 U S 418), yet it is subject to State control through the licensing power, the taxing power and the police power. The right of governmental authority to require a licence for the privilege of conducting business is not peculiar to the theatre, but exists likewise in many other private enterprises. The taxing power affects theatres in the same manner as it affects other private concerns The police power goes further in that the State has a right of increased control, since the health or morals of people may be affected Censorship, in the sense of prior restraint, has been held constitutional as applied to motion pictures (*Mutual Film Corporation* v. *Industrial Commission of Ohio* [1915], 236 U S. 230). There is no such censorship of the theatre but productions are subject to penal statutes prohibiting obscenity Where the statutes are drastic, as in New York State under the Wales law (Penal Law, Sect 1140-A), those engaged in a play may be prosecuted if a line, scene or incident is indecent, and in case of conviction of those charged, the licence to operate the theatre may be revoked for a year. In a sense this is more drastic than any censorship since, because of the rigorous penalty, a mere threat by a prosecuting official may result in stopping a play.

A theatre ticket may be in the form of a revocable licence or of a contract If the former it may be revoked at the will of the proprietor; if the latter it may be non-transferable or otherwise conditioned (*Tyson and Brother* v *Banton* [1927], 273 U.S 418, 440). The producer is entitled to bar any person from the premises (*Woollcott* v. *Shubert* [1916], 217 N.Y. 212). If this is done the purchaser of a ticket may merely claim breach of contract and demand the return of his money and the repayment of any ex-

pense incurred (*Luxenberg* v *Keith and Proctor Amusement Co.* [1909], N.Y. 64 Misc 69; *People ex rel. Burnham* v *Flynn* [1907], 189 N Y. 180) The auditor, however, may acquire greater rights if once he has taken a seat (see *Cremore* v. *Huber* [1897], 18 N Y A D 231). A theatre has the right to refuse to accept tickets purchased from a speculator (*Collister* v *Hayman* [1905], 183 N.Y. 250).

The only limitation upon the right of a theatre to discriminate is found in "civil rights" laws which exist in a large number of States (*see* New York Civil Rights Law, Section 40, for type of statute), which laws provide that no discrimination shall be made in any place of public accommodation, resort or amusement because of race, creed or colour Violation is ordinarily a misdemeanour and subjects the wrongdoer to penalty payable to the party aggrieved (*Joyner* v. *Moore-Wiggins Co Ltd.* [1912], 152 N Y. App Div. 266, affirmed 211 N Y 522) Under these laws a dance hall is not regarded as a place of public accommodation (*Johnson* v *Auburn and Syracuse Electric R R Co* [1915], 169 A.D 1864).

A law providing for the limitation of the amount that speculators or agencies may charge has been held unconstitutional (*Tyson and Brother* v. *Banton* [1927], 273 U S. 418). On the other hand, tax laws assessing agencies to an almost prohibitive amount have been held constitutional by the circuit court of appeals in New York (*Alexander Theatre Ticket Office, Inc.*, v *United States*, 23 Fed, 2d series [1927], p. 44). The proprietor is not an insurer of persons or property in the theatre As respects either, he is liable only in case of negligence (property: *Pattison* v. *Hammerstein* [1896], N Y. 17 Misc. Rep 375 Person *Dunning* v *Jacobs* [1895], N Y 15 Misc 85; *Flanagan* v *Goldberg* [1910], 137 N.Y App Div 92), although it has been held that he warrants the premises to be reasonably safe (*Weiner* v. *Scherer* [1909], N.Y., 64 Misc 82)

Laws providing for Sunday closing have been held constitutional (*Lindenmuller* v. *The People* [1861], 33 Barb [N Y] 548).

Questions concerning relations between managers and authors, actors and others connected with the profession depend upon contract Within recent years in the United States various groups have been organized The Actors' Equity Association, which includes practically all actors of note and which is affiliated with the American Federation of Labor, demands a certain type of contract for actors The Dramatists' Guild of the Authors' League of America, which in its membership includes practically all playwrights, insists upon a minimum basic agreement limiting the rights of managers in dealing with its members The Authors' and Composers' League includes in its membership all musical writers of note, and controls the "small rights" connected with presentation.

See *Encyclopaedia of Law* and cases above cited. (A G. H.)

Other Countries.—In Scotland the Theatres Act, 1843, and the Burgh Police Act, 1892, regulate the licensing of theatres and other places of public entertainment. There is no stage censorship in Ireland In the United States of America public entertainments are governed by State legislation, the only act of Congress affecting theatres, etc, being a revenue act, passed in 1829, imposing taxes on admissions to public entertainments on somewhat similar lines to the English entertainment tax. There is usually no censorship of plays, but performances are subject to police supervision and prosecution if they offend.

In Continental Europe Sunday performances are lawful In most European countries (but Denmark is an exception) there is no State censorship, the regulation and supervision of stage plays and other public entertainments being placed in the hands of the police or the local municipal authorities.

THEATRICAL MAKE-UP AND COSMETICS: *see* MAKE-UP AND COSMETICS; MOTION PICTURE MAKE-UP.

THEBAINE, an opium alkaloid, $C_{19}H_{21}NO_3$, of the phenanthrene group (*see* ALKALOIDS and MORPHINE).

THEBES, an ancient Greek city in Boeotia (anciently Θῆβαι *Thebae*), is situated on low hilly ground a little north of the Asopus valley, overlooking the Ismenian plain, about 44 m. from Athens, whence it is reached by two carriage-roads and by railway It has about 4,800 inhabitants, and is the seat of a bishop. The present town occupies the site of the ancient citadel, the Cadmea; two fragments of ancient wall are visible on the N. and another, belonging either to the citadel or the outer wall, on the S There are remains of a Minoan "palace," and chamber-tombs The church of St. Luke, south-east of the Cadmea, is believed to contain his tomb. Two streams, rising a little south of the town, flow on the two sides, the ancient Ismenus on the east and Dirce Δ(ηl)κρ on the west The "waters" of Thebes are celebrated by Pindar and the Athenian poets, and the site is still, as described by Dicaearchus (3rd century B C), "all springs," κάθυδρος πᾶσα. From the abundance of water the neighbouring plain is extremely fertile. But the population is scanty, and the town unimportant

History.—The record of the earliest days of Thebes was preserved in a mass of legends. Five main cycles of story may be distinguished: (1) the foundation of the citadel Cadmeia by Cadmus; (2) the building of a "seven-gated" wall by Amphion, and the cognate stories, (3) the tale of the "house of Laius," culminating in the adventures of Oedipus and the wars of the "Seven" and the Epigoni; (4) the advent of Dionysus; and (5) the exploits of Heracles It is difficult to extract any historical fact out of this maze of myths; at most it seems safe to infer that it was one of the first Greek fortified cities

In the period of great invasions from the north Thebes received settlers of that stock which spread over Boeotia The military security of the city tended to raise it to a commanding position and its inhabitants endeavoured to establish a complete supremacy over the outlying towns. In the late 6th century the Thebans were brought into hostile contact with the Athenians, who helped the small fortress of Plataea to maintain its independence against them. The aversion to Athens explains the attitude of Thebes during the great Persian invasion, though it should be remembered that Herodotus, our chief authority for the period, wrote this part of his history in all probability at a period when feeling between Athens and Thebes was bitter in the extreme Though a contingent of 700 was sent to Thermopylae (480 B C) and remained there with Leonidas to the end, the governing aristocracy soon after joined the enemy and fought zealously on his behalf at the battle of Plataea (479 B C.). The victorious Greeks punished Thebes by depriving it of the presidency of the Boeotian League In 457 B C Sparta, needing a counterpoise against Athens in central Greece, reinstated Thebes as the dominant power in Boeotia The great fortress served this purpose well by holding out when the Athenians overran and occupied the rest of the country (457–447 B C). In the Peloponnesian War (*q v*) the Thebans, embittered by the support which Athens gave to the smaller Boeotian towns, and especially to Plataea, were firm allies of Sparta, which helped them to besiege Plataea and allowed them to destroy the town after capture (427 B C.). In 424 B C. at the head of the Boeotian levy, they inflicted a severe defeat upon an invading force of Athenians at Delium After the downfall of Athens at the end of the Peloponnesian war the Thebans, finding that Sparta intended to protect the states which they desired to annex, broke off the alliance. In 404 B C. they had urged the complete destruction of Athens, in 403 B C they secretly supported the restoration of its democracy in order to find in it a counterpoise against Sparta. A few years later, they forced on the so-called Corinthian War and formed the nucleus of the league against Sparta. The result of the war was disastrous to Thebes as the settlement of 387 B C. stipulated the autonomy of all Greek towns and so withdrew the other Boeotians from its political control Its power was further curtailed in 382 B.C., when a Spartan force occupied the citadel by a treacherous *coup-de-main*. Three years later the Spartan garrison was expelled;

in the consequent wars with Sparta the Theban army, trained and led by Epameinondas and Pelopidas (*qq v.*), proved itself the best in Greece. Some years of desultory fighting culminated in 371 B C. in a victory over the Spartans at Leuctra (*q.v.*). The winners carried their arms into Peloponnesus and at the head of a large coalition permanently crippled the power of Sparta. But the predominance of Thebes was short-lived The states which she protected were indisposed to commit themselves permanently to her tutelage, and the renewed rivalry of Athens prevented the formation of a Theban empire. With the death of Epameinondas in 362 B C the city sank again to the position of a secondary power. In a war with Phocis (356–346 B.C) it could not even maintain its predominance in central Greece, and by inviting Philip II. of Macedon to crush the Phocians it extended that monarch's power within dangerous proximity to its frontiers In 338 B.C. the orator Demosthenes persuaded Thebes to join Athens in a final attempt to bar Philip's advance upon Attica. The Theban contingent fought bravely in the decisive battle of Chaeroneia (*q v*) Philip was content to deprive Thebes of her dominion over Boeotia, but a revolt against Alexander was punished by the complete destruction of the city Thebes never again played a prominent part in history It suffered from the establishment of Chalcis as the chief fortress of central Greece, and was severely handled by the Roman conquerors Mummius and Sulla In Pausanias's time (A D. 170) its citadel alone was inhabited During the Byzantine period it served as a place of refuge against foreign invaders, and from the 10th century became a centre of the new silk trade In 1311 it was destroyed by the Catalans and passed out of history

The most famous monument of ancient Thebes was the outer wall with its seven gates, which even as late as the 6th century B C was probably the largest of artificial Greek fortresses. Two of the springs have been identified with some probability—that of St Theodore with the Oedipodeia, in which Oedipus is said to have purged himself from the pollution of homicide, and the Paraporti with the dragon-guarded fountain of Ares (*see* CADMUS). From the interest of the site in history and still more in literature, as the scene of so many dramas, the temptation to fix details has been specially strong There are two main difficulties to contend with. The description of Pausanias was written at a time when the lower city was deserted, and only the temples and the gates left; and the references to Thebes in the Attic dramatists are, like those to Mycenae and Argos, of no topographical value.

THEBES (Θῆβαι), the Greek name of the ancient capital of Upper Egypt. It occurs in Homer (*Il.* ix. 381–4) where it has the epithet ἑκατόμπυλος, "hundred-gated," probably derived in the first place from the gateways of its endless temples, for Thebes was never a walled city with gates, though its vast temple enclosures in different quarters would form as many fortresses in case of siege or tumult Its Egyptian name was Wesi (or Wis?), later Ne, "the city" (sometimes Ne-Amun, hence No-Amon in Nahum iii. 8). Ammon, Amen-Ra, or Amenrasonther ("Ammon-Ra king of the gods") was its deity, with his consort Mūt and their child Khons Mont also was a local deity and Hathor presided over the western cliffs of Thebes. In very ancient times the city lay on the east bank, the necropolis on the west. The chief nucleus of the ancient Wēsi was a town about the temple of Karnak: it probably reaches back to the prehistoric period At Drah abu'l nagga, opposite to it, are tombs of its princes under the VIth Dynasty The temple of Karnak is no doubt of immemorial antiquity. In it Senusret I. dedicated statues to his predecessors of the Vth Dynasty who had probably showed their devotion to Ammon in a substantial manner, and Cheops of the IVth Dynasty is named in it. After the end of the Old Kingdom Thebes grew from an obscure provincial town to be the seat of a strong line of princes who contended for supremacy with Heracleopolis and eventually triumphed in the XIth Dynasty The most important monument of the Middle Kingdom now extant at Thebes is the funerary temple of Mentuhotep III. at Deir el Bahri The name Amenemhet, so common in the XIIth Dynasty, shows the importance of the Theban god at this time It was, however, the early rulers of the XVIIIth Dynasty down to Tethmosis III. who developed Karnak, and on the west bank built the great funerary temple of Deir el Bahri and smaller temples as far south as Medinet Habu, and began the long series of royal tombs in the lonely Valley of the Kings far back in the desert Amenophis III continuing, transformed western Thebes monumentally. built three great temples in addition, that of Mont on the north of Karnak the temple of Mut on the south and the temple of Ammon at Luxor, and connected the last two with the state temple of Karnak by avenues of sphinxes The city and its monuments now covered an area about three miles square After this Thebes experienced a serious set-back with the heresy of Ikhnaton, the son of Amenophis III. He moved his capital northward to Akhetaton (El Amarna) and strove to suppress the worship of Ammon, doing infinite damage to the monuments of Thebes by defacing his name and figure After about twenty years, however, the reaction came, Thebes was again the capital and a little later under Seti (Sethos) I and Rameses II. of the XXth Dynasty it was raised to greater architectural magnificence than ever These two kings built the great columnar hall of Karnak, added a large court with pylons to Luxor, and on the west bank built the funerary temple of Seti at Kurna, and the Ramesseum with its gigantic colossus, besides other edifices of which only traces remain. Under the XVIIIth and XIXth Dynasties Thebes was at the height of its greatness. Conquering Pharaohs brought home trains of prisoners and spoil, embassies came thither of strange people in every variety of costume and of every hue of skin, from Ethiopia, Puoni (Punt), Mesopotamia, Asia Minor, Libya, and the islands of the Mediterranean, bringing precious stones, rare animals, beautiful slaves, costly garments and vessels of gold and silver The tombs of the XVIIIth Dynasty on the west bank and the sculptures in the temples reflect the brilliancy of these days. but with Rameses II came the turning-point of its glories, and the efforts of all his successors combined could add little to the wonders of Thebes The temple and tower of Rameses III (XXth Dynasty) at Medinet Habu, his tomb in the Biban el Moluk, the temple of Khons (Rameses III and later) and the court of Sheshonk I. (XXIInd Dynasty) at Karnak are the only great achievements

The tide of prosperity was now flowing northward and such monumental energy as remained was expended more widely. For several centuries after the fall of the New Empire Thebes was but one of several alternating or contemporaneous capitals Memphis, Tanis, Bubastis, Sais, Heracleopolis had at one time or another at least equal claims The Ethiopian conquerors of Egypt made Thebes their Egyptian capital, but in 668 Assur-bani-pal sacked the city Psammetichus did not neglect it, but Ptolemy I gave a new capital to the upper country in the Greek foundation of Ptolemais, and thus struck a fresh blow at the prosperity of Thebes For a short period in the reign of Epiphanes, when Upper Egypt was in rebellion against the Ptolemaic rule, Thebes was the capital of independent native dynasts. In a later rebellion, Thebes was captured after a three years' siege and severely punished by Lathyrus (Ptolemy X, Soter II). In the reign of Augustus, having joined in the insurrection against the tax-gatherers, it was destroyed by Cornelius Gallus and became a collection of villages Though its vast buildings have since served as quarries for mill-stones and for the lime-burner, Thebes still offers the greatest assemblage of monumental ruins in the world

We will now briefly enumerate the principal groups of monuments. On the east bank at Karnak stand the great state temple of Amen-Ra with its obelisks of Hatshepsut and Tethmosis I and the vast columnar hall of Rameses II ; the temple of Mūt and the well-preserved temple of Khons; the temple of Luxor and avenues of rams and sphinxes connecting all these. On the west bank, in front of the necropolis, on the edge of the desert or projecting into the cultivation, was a low row of temples· the north-

ernmost, placed far in front of the others, is the well-preserved temple of Seti I at Kurna; then follow the Ramesseum and Medinet Habu; and the foundations of many others can be traced The temple of Amenophis III, to which the colossi of "Memnon" were attached, was again far forward of the line. The Ramesseum contains the remains of a stupendous seated colossus, in black granite, of its builder Rameses II., thrown on its face. When perfect it was probably 57 ft. high and weighed about 1,000 tons, surpassing the "Memnon" statues of Amenophis III in size and weight The temple of Rameses III at Medinet Habu, sculptured with very interesting scenes from his Syrian, Libyan and other wars and from religious festivals, is remarkable also for the unique entrance-tower which probably formed part of the royal palace Northward and far back in the foot-hills is the Ptolemaic temple of Deir el Medina, and beyond under the cliffs of Deir el Bahri the terrace temple of Queen Hatshepsut, the walls of which are adorned with scenes from her expedition to Puoni (Somaliland) in search of incense trees, and many other subjects Far behind Medinet Habu are the Tombs of the Queens, where royal relatives of the XXth Dynasty are buried, and immediately behind the lofty cliffs of Deir el Bahri, but accessible only by a very circuitous route from Kurna, are the Tombs of the Kings (from Tethmosis I onward to the end of the XXth Dynasty) in the Biban el Moluk and the Western Valley Those of Seti I and Rameses III are the most remarkable These royal sepulchres are long galleries excavated in the rock with chambers at intervals. in one of the innermost chambers was laid the body in its sarcophagus. In the XXIst Dynasty, when tomb robberies were rife and most of their valuables had been stolen, the royal mummies were removed from place to place and at last deposited for safety in the tomb of Amenophis II. and in the burial-place of the priest-kings at Deir el Bahri The finding of the two *cachettes* nearly intact has been among the greatest marvels of archaeological discovery. The systematic exploration of the Valley of the Tombs of the Kings has been annually rewarded with results of the highest interest The greatest as well as the most recent of these is the discovery in Oct 1922 of the tomb of Tutankhamun (reigned 1360–1350 B C) with its magnificent equipment almost intact

Daressy, *Notice explicative des ruines de Medinet Habu* (Cairo, 1897), G Maspero, "Les Momies royales de Deir el Bahari" in *Mémoires de la mission archéologique française au Caire*, tome I, and many other works (F Ll G; X)

THECLA, ST., one of the most celebrated saints in the Greek Church (where she is commemorated on Sept. 24) and in the Latin Church (where her festival is Sept. 23) She is honoured with the title of "protomartyr" The centre of her cult was Seleucia, in Isauria Her basilica, south of Seleucia, on the mountain, long a popular place of pilgrimage, is mentioned in the two books of St Basil of Seleucia According to her *Acta*, Thecla came under the personal teaching of the apostle Paul at Iconium. In spite of their highly fabulous character (Thecla escaped from burning, from wild beasts, bulls and serpents), which caused them to be more than once condemned by the Church, the *Acta* of Paul and Thecla, which date back to the 2nd century, are interesting monuments of ancient Christian literature

See *Acta Sanctorum*, September, vi 546–568, J. A. Lipsius, *Acta apostolorum apocrypha* (Leipzig, 1891), i 235–269, C Schmidt, *Acta Pauli* (Leipzig, 1905), where an attempt is made to prove that the *Acta* of Paul and Thecla formed an integral part of the *Acta Pauli*; *see* also Apocryphal Literature, C Holzey, *Die Thekla-Akten, ihre Verbreitung und Beurtheilung in der Kirche* (Munich, 1905)

THEGN or **THANE,** an Anglo-Saxon word meaning an attendant, servant, retainer or official From the first, however, it had a military significance, and its usual Latin translation was *miles*, although *minister* was often used The word is used only once in the laws before the time of Aethelstan (*c* 895–940), but more frequently in the charters

The thegn became a member of a territorial nobility, and the dignity of thegnhood was attainable by those who fulfilled certain conditions In like manner a successful thegn might hope to become an earl There were others who were thegns on account of their birth, and thus thegnhood was partly inherited and partly acquired The thegn was inferior to the aethel, the member of a kingly family, but he was superior to the ceorl. The status of the thegn is shown by his wergild Over a large part of England the amount of this was fixed at 1,200 shillings, or six times that of the ceorl. He was the twelfhynde man of the laws

The increase in the number of thegns produced in time a subdivision of the order There arose a class of king's thegns, corresponding to the earlier thegns, and a larger class of inferior thegns, some of them the thegns of bishops or of other thegns. A king's thegn was a person of great importance, the contemporary idea being shown by the Latin translation of the word as *comes* He had certain special privileges No one save the king had the right of jurisdiction over him, while by a law of Canute we learn that he paid a larger heriot than an ordinary thegn

The 12 senior thegns of the hundred play a part, the nature of which is rather doubtful, in the development of the English system of justice By a law of Aethelred they "seem to have acted as the judicial committee of the court for the purposes of accusation" (Holdsworth, *Hist Eng Law*, vol i, 1921), and thus they have some connection with the grand jury of modern times

The word thane was used in Scotland until the 15th century to describe an hereditary non-military tenant of the Crown

THEINNI (now **HSENWI**) *see* Shan States

THEISM, in the broadest sense, means belief in God The word, however, is used generally with the implication that the belief is held in a conscious and rational manner, and hence Theism is usually applied only to a system of beliefs which has some claim to be regarded as a philosophy. According to the Oxford Dictionary the first occurrence of the word is in Cudworth's *Intellectual System of the Universe* (1678) The etymology of the word (*θεός*) would suggest that it might cover any conception of the universe which admitted the existence of Deity, but in practice Theism has come to mean a belief in one God, and the word is not easily distinguished from Monotheism, save that Theism has a more theoretical implication

Theism as a philosophical and theological position may be distinguished from other theories It is, of course, the direct antithesis to Atheism (*q v*), which, strictly speaking, is the denial that God exists It is to be distinguished, again, from Agnosticism (*q v*), the view that there is no sufficient ground for either an affirmative or negative answer to the question: Does God exist? and that the only rational attitude is absolute suspense of judgment It should be observed, however, that there is a sense of the word Agnosticism which is not wholly incompatible with Theistic belief The theory of Herbert Spencer, that we can know that an Ultimate Reality exists but can also know that that Reality is unknowable, is sometimes described as agnosticism Herbert Spencer's theory, as it stands, is plainly absurd, because in order to know that the Ultimate Reality is unknowable we must know enough of the nature of the Unknowable to be justified in making this assertion about it All reflective Theists would acknowledge, however, that there is an element of truth in the Agnostic position—the human mind is incapable of grasping completely the nature of the Divine, and though there is a genuine knowledge of God. for finite mind that knowledge must always be incomplete. It is customary to distinguish Theism from Deism (*q.v.*)

The Deists were writers on natural religion in the 18th century who shared the desire to set religion on a purely rational basis and tended, in a greater or less degree, to exclude the ideas of revelation and mystery, reducing Christianity to those truths which, it was alleged, could be attained by the unaided reason. Though some of these authors had pantheistic tendencies, the name Deism has been given to that type of theology which considers God and the world to be absolutely distinct from one another, thus conceiving the Deity as an external Creator and Governor. In the language of modern philosophy Deism is the view which emphasises the transcendence of God but denies His immanence. In contrast to Deism, Theism affirms the presence of God in the world, holding both immanence and transcendence. Pantheism (*q.v*) presents a contrast to Theism of the opposite kind to that which we have found in Deism Pantheistic systems,

though widely different from one another in spirit and presentation, agree in making an identification between God and the Universe. It is sometimes said that Pantheism maintains divine immanence while eliminating from its creed every vestige of divine transcendence. This manner of expression, though open to criticism, has the merit of making clear the main difference between Pantheism and both Deism and Theism. Certain philosophical systems may be classified for this purpose under the head of Pantheism. Spinoza's philosophy of God as the Infinite Substance and some forms of Absolute Idealism, as for example, that represented in England by the late F. H. Bradley cannot be described as theistic in the narrow sense of that word and are, theologically considered, pantheistic in tendency. Dualism is to be regarded as another theory which, in some of its forms, has affinities with Theism but is in essence different. Properly, Dualism means a view of the world which attributes its existence to two different or possibly antagonistic principles both equally ultimate, whether those principles be conceived as two deities, as in some forms of Zoroastrianism, or God and matter as in Manichaeism. A modified Dualism enters into most Theistic theories, but no theory could be called fully Theistic which was satisfied with a final Dualism.

We may now proceed to state in a positive manner the general tenets of Theism. It must be remembered that pure Theism has never been a widely influential religious belief. In the historical religions Theism is mixed with other elements, or rather perhaps is the basis of them. Thus Christianity is a Theistic religion, but its distinctive characteristic is the doctrine of the Incarnation. In the same way, Mohammedanism is Theism modified by special beliefs about the revelation of Allah through Mohammed. The fundamental conception of Theism in all its developed forms is that of a Being who is at once the supreme Value and the Source of all finite existence. Theism has usually thought of the Supreme Being as in some sense personal, or at least as One with whom personal relations were possible. This Supreme Being, in Anselm's phrase, *id quo majus cogitari non potest,* is, in the Theistic view, neither identical with the Universe nor wholly aloof and separate from it. The relation of God as Cause with the world has been conceived in various ways, the most common being creation, which itself may be capable of more than one interpretation. The idea of emanation, however, has also been employed, as in the Neo-Platonic philosophy (chief exponent Plotinus, A.D. 204–270) which exercised a considerable influence upon Christian theology. The peculiarly Theistic doctrine of the relation of God with the world is often expressed by the phrase, "God is both transcendent and immanent."

ARGUMENTS FOR THEISM

Theism, being a reflective theory and not simply a religious faith, has sought to defend its position by rational arguments. Historically, three arguments have been supremely important and are sometimes known as the "traditional proofs." They are the Cosmological, the Teleological, and the Ontological arguments.

The first philosopher, at least in the West, to state an argument which he held to be demonstrative of the existence of God is Plato. The proof which he gives (in the *Laws* X.) is the starting point of the rational theology or "natural" theology which claims to establish the being of God on the ground of reason. The *Laws* is universally admitted to be the work of Plato's old age. In his earlier writings Plato had made use of the idea of God and indeed the conception was central in his thought. He had constantly protested against unworthy ideas of the divine and asserts both in the *Republic* and *Theaetetus* that God is perfectly good and cannot be the cause of evil. The proof in the *Laws* may be regarded as the fruit of long reflection on the problem and contains the germ of much subsequent development. The proof turns upon the existence of motion and change. Motions and changes may be divided into several classes, but there is one fundamental distinction, that between spontaneous and communicated motion. It can be shown that spontaneous motion must be prior to communicated motion, since if there is motion at all it cannot all be communicated. Now the soul is the source of spontaneous motion, as distinguished from matter which can only receive communicated motion. Hence the soul is prior to the body. The motions in the Universe which have no human origin must likewise be referred to a soul. We are thus led to the conception of a Soul of the world. But the motions of the Universe, and in particular of the heavenly bodies, are orderly and thus indicate that the World Soul is rational and good, the "mind which ordered the universe." In Plato's argument two of the "rational" proofs are joined—the Cosmological (from the existence of a universe in which motion exists to a Source of motion), and the Teleological (from the existence of order to the Divine Mind as its ground). It will be convenient to consider these arguments in their subsequent formulations separately.

The Cosmological Argument.—The philosophy of Aristotle is not, like that of Plato, profoundly religious in spirit, and the concept of God in Aristotle's thought has little religious significance, being mainly a metaphysical conclusion; but the formulation of the cosmological argument by Aristotle has been of primary importance for Christian philosophy. Like his master Plato, Aristotle rises to the thought of God from the fact of change and motion (κίνησις) which means for him much more than change of place. Motion is conceived by Aristotle as the passage from potentiality to actuality (δύναμις and ἐνέργεια). Every change which actually occurs is the realization of a potentiality which was hitherto latent. Associated with this conception is Aristotle's doctrine of "form" and "matter." Every concrete and finite existence is composed of matter and form and it is the latter which gives to it a specific nature. In "sublunary" existences the expression of form is always imperfect, the matter never being absorbed in the form completely. The motion and change of the world are therefore explained as the striving of the potential to become actual, of the forms to become fully realised. The universe which is in constant motion is not, however, self-explanatory; the change must have some source beyond itself. This source is God, who must be conceived as at once the First Mover and the Unmoved. There can be nothing higher than God, otherwise He himself would be moved towards that higher being. God must exist or there would be no movement. God is therefore pure form and pure actuality, in Him there is no "matter" and no potentiality. He is the realization of all form and of all potentiality. Thus God moves the world ὡς ἐρώμενον, as an object of desire; but it is an essential part of Aristotle's view that God does not desire or need the world. The world is not even known to Him as it exists in actuality. He contemplates the pure forms which are the content of His own intellect. The outcome of Aristotle's reflection is then a Deity who is completely transcendent and pure thought. All personal relations with the world, every trace of emotion and even moral goodness is excluded from his nature which is described as a thinking of thought (νόησις νοήσεως) (Aristotle, *Physics,* Bk. VIII., *Metaphysics,* Bk. XII.)

It is one of the curiosities of history that a theology so "intellectualist" should have profoundly influenced the thought of Christianity which is in spirit widely different from that of Aristotle. Yet the Aristotelian logic and metaphysics formed the basis of the great constructive systems of the middle ages, the scholastic theology, of which the greatest representative is St. Thomas Aquinas (1227–1274). The cosmological argument forms the basis of St. Thomas's rational theology. It was a fundamental conviction with him that the *preambula fidei,* the foundation truths of religion, were demonstrable by the human reason without the aid of Revelation. In his greatest, though unfinished work, the *Summa Theologica* (Pt. I., Quaest. ii., art. 3), he gives five proofs of the existence of God, of which four are versions of the cosmological argument. (1) The argument from ***motion:*** "Any thing which is moved is moved by some other thing . . . one thing moves another in so far as the former is in actuality, for to move is nothing else than to draw anything from potentiality to actuality. But nothing can be brought from potentiality into actuality except by means of something which is already in actuality. . . . It is impossible that in the same respect and the same manner anything should be both moving and unmoved, or be self-moved." We cannot go on to infinity in the series of

"movers" which are themselves moved, for in that case there would be no first source of movement and consequently no movement at all We must then conclude that there is a first source of movement which is moved by nothing else—*i.e*, God. (2) The argument from *Efficient Causes:* Experience shows that there is an order of efficient causes Nothing can be the cause of itself, for that would imply that it was prior to itself We cannot rest content with an indefinite series of causes and effects, because if there is no First Cause there can be no last effect Hence we conclude that there is a First and Uncaused Cause—*i e*, God (3) Argument from *possible and necessary existence:* Some existences are possible and not necessary, *i e*, they may exist or not exist, being generated and corrupted But all existence cannot be of this nature, for unless there were necessary existence there would be no ground for possible existence If there are necessary existences there must be an existence which is necessary in itself and does not derive the necessity of its existence from some other necessary existence. An indefinite regress is as impossible here as in the case of efficient causes There must therefore be Something which is necessary *per se*—*i e*, God. (4) Argument from *degree of quality or value:* We find things more or less "good," "true" and "excellent" "More" or "less" is predicated according to degree of approach to a "greatest." There is therefore something which is most true, good and excellent—*i e.*, God

It should be observed that the first two forms of Aquinas' cosmological argument lead to the conception of a purely Transcendent Deity while the latter two suggest immanence

The cosmological argument, very much in the form which was given to it by Aristotle and Aquinas, appears as a fundamental element in many philosophies Mention must be made of Leibniz who supplemented it by laying down a new law of thought—the law of "sufficient reason"—according to which "for everything there must be a sufficient reason why it is so and not otherwise," thus making it clear that, for him, the basis of the cosmological argument was not empirical observation but a rational and self-evident principle—that of universal causation

The objections to the traditional cosmological argument have been formulated by Hume and Kant The former struck a blow at the simplest and most obvious version of the argument—that to a First Cause—by his sceptical analysis of the ideas of cause and necessary connection, though it should be noticed that he himself appears to have retained the conviction that the conception of a First Cause could not wholly be abandoned In Hume's view, however, there is no universal principle of causation The idea of necessary connection between phenomena is derived from habit breeding expectation, and the so-called "principle of causation" is due to nothing more than "the mind's propensity to feign," *i.e*, it is a convenient fiction Obviously this view, which was but the logical conclusion of the empirical movement in English philosophy, undermines the whole of our knowledge of the natural order and physical science, but it has also a direct bearing on the cosmological argument, for if causation is a principle on which we cannot rely when dealing with phenomena, we cannot use it to take us beyond phenomena to God. Kant attempted to save our knowledge of Nature from Hume's sceptical objections. He did so in a somewhat equivocal fashion He held that the "categories" which the mind employs in synthesizing perception (cause, substance, etc) are *a priori* in the sense that the mind does not derive them from experience but necessarily uses them in ordering experience—in short that Nature apart from Mind has no existence, but in some sense "Mind makes Nature" Kant is emphatic, however, in his limitation of this principle The categories of the understanding are confined to dealing with phenomena. The use of such a category as causation to carry us beyond phenomena to a super-phenomenal Reality is an illegitimate—a "transcendent"—use This is the real ground of Kant's objection; it is based upon his rigid limitation of the understanding to phenomena. Some special criticisms are also of permanent interest Kant points out that the argument, in the only form which he discusses (that of efficient causation), does not, even if sound, lead to the conclusion that God exists, but only that a First Cause of some kind exists, and in order to attain the conception of God we need another argument—the Ontological With reference to the alleged impossibility of conceiving an infinite series of causes, Kant remarks that the inconceivability attaches also to the idea of an uncaused cause, and there is therefore no reason why the mind should embrace one alternative rather than the other

In spite of the objections to which the traditional form is open, the cosmological argument in a wider application has kept its power. In modern philosophy all those systems which employ the idea of an Absolute Reality arrive at the Absolute by some kind of cosmological argument. An important example of this is found in the Theistic philosophy of Hermann Lotze The impossibility of rendering intelligible the fact of "transeunt" causation (*i.e*, that change in one thing is the occasion of change in another thing), so long as we conceive the ultimate reality to consist of a collection of independent "reals" leads to the conception of an all embracing Absolute of which the particular things and their changes are modifications Arguments of this type lead rather to an immanent Deity than to the transcendent God of Aristotle and Aquinas

The cosmological argument has permanent value, though it has not the demonstrative force which was formerly attributed to it. It serves to substantiate the conclusion that "nature," whatever we may mean by that term, is not a self-explanatory system, and therefore to support the Theistic view as preferable on rational grounds to rival hypotheses The form of the cosmological argument which begins with the apprehension of values, such as goodness and truth, has received little attention in the history of thought, but is one which has most positive weight for modern philosophy. Modern Theism would lay great stress on the contention that the existence of goodness, beauty and truth in finite experience compels us to postulate an absolute Goodness, Beauty and Truth

The Teleological Argument.—This argument, sometimes called "the argument from design," is rightly described by Kant as the most impressive, the most easily comprehended of the traditional "proofs." Like the cosmological argument it is *a posteriori* in character, since it starts with the observed facts of adaptation to ends in the natural world. As we have seen, however, when referring to Plato, the teleological argument may be based upon the more general consideration of the order of the universe. The purposive character of the events of the world was a common topic of Stoic philosophers in connection with their doctrine of Providence. Here again we may turn to Thomas Aquinas for a succinct statement of the argument in its common form It is the fifth proof of the existence of God given by that philosopher —the proof from the *gubernatio* of things. "Some things which have no power of knowing, such as natural bodies, work for ends, as is manifest from their constantly, or at least frequently, working in the same way for the attainment of that which is best. . Now such things as have no power of knowing do not tend towards an end unless they are directed by some being which has knowledge and intelligence" (*Summa Theologica*, Pt I Quaest. ii. art. 3) It will be noticed that there are two elements in this argument (a) the observation of "working for ends"; (b) the inference from this to a directing Intelligence

The evidence for working for ends or the adaptation to purposes on which stress is laid has varied; at times the main emphasis has been on general adaptation of the Universe to the existence and well-being of men or, more abstractly, to the production of values; at other times the argument has turned chiefly upon special instances of apparent design as, *e.g.*, the human eye. The latter type of reasoning was prominent among the rationalist Theologians of the 18th and 19th centuries. Paley's *Natural Theology*, with its famous analogy between the eye and a watch, is a familiar example of this kind of presentation.

Before proceeding to a discussion of the present position of the teleological argument it will be well to note the objections and limitations which arise on a consideration of the argument itself. These again have been clearly stated by Kant. It is obvious that the argument by itself is not sufficient to demonstrate the existence of God. Even if it be admitted that there are evidences of design, it does not follow that they are due to one Mind. The facts

might be explained on the hypothesis of several intelligences. It is only when we have reached the conclusion on other grounds that the Source of Being is one, that the teleological argument may tend to show that Source to be intelligent. The argument again, tends to suggest an analogy with the carpenter or sculptor who makes the best of his material and thus to lead to the conception of God as the Architect of the Universe working upon alien material. It may be alleged further, that the argument is based upon purely subjective estimates, and implies an absurdly anthropocentric conception of the universe. It cannot be denied that the teleological conception has frequently been carried to ridiculous extremes, and attempts have been made to show that this is the "best of all possible worlds" in the sense that all its features minister to human convenience; but these extremes are no necessary part of the argument, and it may be observed that Kant himself, in the *Critique of Judgement*, allowed that the teleological judgment is necessary and inevitable in dealing with living beings and the appreciation of the beautiful.

A permanent difficulty for the teleological argument is the existence of evil, particularly of pain, waste, and the missing of apparent ends If stress is laid on the "working towards ends" which are good, stress should equally be laid upon the working towards ends which to us appear to be bad. Additional weight has been given to this objection by the evolutionary theory of the origin of species through the struggle for existence and the survival of the fittest. The Darwinian theory of evolution seems to make death, defeat, and their concomitant pain, a necessary part of the evolutionary process. On these and other grounds it has been held, by Guyau, Bertrand Russell and many others, that there is neither beneficent nor maleficent purpose in the world, but that Nature is indifferent to the hopes, aspirations and needs of man Some answer to these objections may be attempted It is argued, for example, that the amount of pain in the lower orders of creation has been greatly exaggerated by the tendency to interpret the experience of the lower animals in terms of our own, and by the neglect of the consideration that the pains of anticipation are absent in sub-human creatures. Suffering in human beings again may be supposed to serve spiritual ends (*see* James Martineau, *A Study of Religion*). The most conclusive answer attempted to the problem of evil as an objection to a teleologically ordered universe is that of Leibniz, who maintained that this is the "best of all possible worlds." Any other world would have contained more evil and less good than the actually existing one This view depends upon Leibniz's conception of the nature of possibility which, according to him, is determined, not by the arbitrary will of God, but by "eternal verities" which are absolutely valid for the Eternal Mind Thus out of an infinite number of possible worlds the Creator chose that which included the greatest sum of good, and the evils in it exist as necessary conditions for the greater sum of good. This theory has been somewhat unfairly summed up by F. H. Bradley in the epigram, "The world is the best of all possible worlds, and everything in it is a necessary evil."

We may remark here that our view of the teleological argument will be profoundly affected by our view of the meaning of "good" and "value" If we are "hedonists," believing that good means pleasure and the absence of pain, the teleological argument will have little weight The Universe is plainly not designed to afford the greatest possible degree of pleasurable feeling If on the other hand, we conceive that value means the development of spiritual and moral persons the argument will appear in a different and more favourable light.

The rise of the evolutionary concept has had another and even more important effect on the teleological argument. The principle of the adaptation of species to their environment by survival of those best adapted has removed the favourite examples of teleology, such as the eye, from the sphere of directly created things and offered a "natural" explanation of their delicate adjustment. The Darwinian and post-Darwinian theories of biological evolution seemed to destroy the basis of the most popular argument for Theism. It was evident that if the argument was valid at all it needed complete restatement. Post-evolutionary exponents of the teleological argument have consequently laid stress, not on particular instances of apparent design, but on the general trend of evolution which, it is maintained, can only be explained by the hypothesis of Divine Providence. A subtle statement of this line of thought is to be found in Lord Balfour's writings, the *Foundations of Belief* and *Humanism and Theism*, in which he urges that, unless there is some intelligent guidance of evolution, the values of truth and beauty cannot be maintained.

The philosophical analysis of the idea of evolution in the present century has led many thinkers to abandon a purely mechanical conception of its method The problem of newness and the development of values has engaged attention M Bergson has completely abandoned the mechanical view and substituted the idea of "creative evolution," new types of existence being in his theory the result of the effort of the *Élan Vital* to achieve freedom. Somewhat analogous is the conception of "emergent evolution" which has been worked out by Professor S Alexander and Professor C. Lloyd Morgan and adopted by several other English authorities. The "emergent" theory of evolution distinguishes between two types of effect, "resultants" which are the predictable outcome of previously existing conditions, and "emergents" which are specifically new and not completely predictable. New species, and in particular new types of being, such as life, consciousness and self-consciousness, would thus belong to the "emergent" type of effect. None of these writers would describe his view of evolution as definitely teleological, and Bergson is as much opposed to teleology as to mechanism, but it is obvious that such conceptions of evolution are leading in the direction of at least "immanent teleology"; and it may be argued that a purely immanent teleology is not by itself an intelligible conception. On the whole then, it may be said that the movement of thought is in favour of a restatement of the teleological argument

The inherent tendency of the human mind to think in the teleological mode suggests that there is really an *a priori* element in the argument The mind is irresistibly impelled to regard the Universe as rational, *i e*, as pervious to its categories and methods of thought. On this irresistible assumption or "act of faith" the whole structure of science is built It is one further step in the same process to regard the Universe as rational in the fullest sense, *i e*, as a teleological system which exists for an end which we can accept as reason for its existence—the production of values or of good

The Ontological Argument.—This is the only one among the traditional "proofs" which is explicitly *a priori* It is the inference from the idea of God to the existence of God, and does not employ any data derived from observation. The argument, though adumbrated by S. Augustine, was first clearly presented by S Anselm (1033–1109) in his work the *Proslogium* Even the fool "who says in his heart, there is no God" has the idea of God, otherwise he would not be able to deny His existence The idea of God is the idea of "that than which no greater can be conceived" (*id quo nihil majus cogitari potest*) Now this idea cannot be in the understanding alone, because if it were, it would not be the idea of that than which there can be nothing greater, for a Being who existed would be greater than a being who did not exist (It should be noticed that *majus* does not mean simply magnitude but includes value) In other words, the idea of the greatest conceivable implies the existence of that Greatest The obvious objection to this line of reasoning was raised by Gaunilo during Anselm's lifetime in his *Liber pro Insipiente* Gaunilo dissented from the passage from idea to existence, and adduced the famous illustration of the "perfect island," which he argued, on Anselm's principle, must exist. The essence of Anselm's reply to this objection is to draw a distinction between that which is the greatest conceivable absolutely and that which is the greatest only relatively as the member of a class. The idea of God is the idea of "that than which nothing greater can be conceived" absolutely, and to this idea alone the ontological argument applies

The subsequent history of the ontological argument has been curious. It has been rejected by many considerable thinkers as a patent fallacy and by others regarded as the foundation of constructive thought Descartes, who is sometimes held to be the

father of modern philosophy, adopted it in two forms as the corner stone of his system, the bridge by which he passed from universal doubt to confidence in the possibility of knowledge. Descartes places in the forefront the consideration of the possession by the mind of the idea of an infinite and perfect being, and the question how this idea can originate. I cannot derive it from myself, because I am certainly neither infinite nor perfect The idea then implies a really existent infinite and perfect Being as its source. Descartes adds an important element to the argument by distinguishing between the positively infinite and the merely "indefinite." The latter is a negative idea implying simply the absence of limits, the former is concrete, and is the idea of God Unless I were in possession of the positive idea of infinity and perfection I should not know myself to be finite and imperfect. Descartes also states the ontological argument very much in the form given to it by Anselm Though in all other instances it is possible to distinguish between essence and existence and to conceive of a being as not existing, this is not possible in the single case of the idea of God "The existence can no more be separated from the essence of God than the idea of a mountain from that of a valley. . . . It is not less impossible to conceive a God, that is, a being supremely perfect to whom existence is wanting, or who is devoid of a certain perfection than to conceive a mountain without a valley" (*Meditations* III and V) The ontological argument was also adopted by Leibniz, who made the addition to it that we need first to demonstrate that the idea of God is the idea of a possible existence

The great flaw in the argument in its traditional form was clearly shown by Kant, who pointed out that it implies existence to be an attribute of the same nature as other attributes the absence of which would constitute imperfection, whereas this is not the case, since every concept we form is of a being as existing in some sense. Kant's illustration however, of the "hundred thalers," which are the same in properties in the imagination as in the pocket though not the same in usefulness, seems to miss the point even more obviously than Gaunilo's perfect island The permanent value in the ontological argument has been emphasised by Hegel It is the necessary attempt to bridge the gulf between thought and things, between concept and reality In this sense it is really at the root of all thought. However we may express it, we are compelled to hold that what the mind necessarily thinks *qua* mind is real, that there is no impassable chasm between the *"ordo idearum"* and the *"ordo rerum"* All philosophies which distinguish between appearance and Reality on the ground that the irrational cannot be the real, rest upon something akin to the ontological argument Probably it would be better to say, "upon an ontological assumption" The ontological argument is, in truth, an attempt to put into the form of a train of reasoning a postulate without which the mind is helpless It may be questioned therefore whether the ontological argument or postulate leads us directly to the God of religious experience It leads rather to the conception of an absolute or rationally coherent system of being

Before leaving the famous "three proofs" a remark must be made on their value for modern Theism. Before Kant's drastic criticism they were taken to be demonstrative proofs of the existence of God at least by the rational theologians It is clear that as demonstrations they are unsatisfactory. This does not mean, however, that they are devoid of value The post-Kantian Theist would, in most cases, adopt a different approach to his problem The central question of constructive philosophy does not present itself to him in the form, given the idea of God as a belief, to find some rational proof of His existence Rather the problem presents itself as analogous to the scientific problem, given the universe as disclosed in experience, to find the most reasonable account of it Several hypotheses present themselves for consideration, among them Theism. The question before the mind of the philosopher, therefore, is to decide which of the possible hypotheses squares most adequately with the whole experience of the universe which is open to us. The Theist maintains that his hypothesis is the most rational in this sense The traditional arguments, on this view, call attention to various aspects of the universe which, when taken up into reflective thought, go to support the Theistic view. Thus in spite of their failure as demonstrative arguments they have great value as indicating lines of thought, suggested by experience, which tend to substantiate the Theistic theory. (For a fuller statement of this *see* W. R Sorley, *Moral Values and the Idea of God*, and W. R. Matthews, *Studies in Christian Philosophy.*)

The change in the method of approach to which we have referred in the preceding paragraph is reflected in the type of argument on which modern Theism has laid greatest stress Though not putting on one side the "rational" proofs, the main appeal in the philosophy of Theism has been to considerations drawn more directly from experience, and particularly from moral and religious experience

The Moral Argument.—Kant is the historical turning-point in the philosophy of religion His criticism of the Theistic proofs was not made in the interest of Atheism, and he was an agnostic only in the technical sense that he denied the possibility of arriving at a knowledge of God by the pure or speculative reason. Religion belongs to the sphere of moral faith, of the "practical reason" There are three postulates of the moral reason, God, Freedom and Immortality, these cannot indeed be proved in any scientific manner, but the consideration of the limits of theoretical knowledge leads us to see that the pure reason cannot disprove their validity. It remains neutral. We are therefore free to affirm the three ideas without which our moral experience of the authority of the moral law and the inexhaustible ideal of holiness could not be conceived as rational This is Kant's fundamental position The train of reasoning by which he seeks to establish the necessity of the postulate of God is less important, being complicated by his peculiar views of the nature of the moral experience The argument turns on the alleged moral demand that the highest holiness should ultimately coincide with the highest happiness

The moral argument has been presented in various forms by important writers of the 19th and 20th centuries Theories of ethics naturally fall into two classes, (1) those which take the fundamental concept in morals to be duty and the moral law, (2) those which take the idea of the Good to be fundamental From both of these standpoints Theistic conclusions have been defended James Martineau in his *Types of Ethical Theory* and *A Study of Religion* adopts on the whole the first, T H Green's *Prolegomena to Ethics* and W R Sorley's *Moral Values and the Idea of God* are salient representatives of the second, while Dr Hastings Rashdall's *Theory of Good and Evil* combines to some extent both points of view

There are three elements in the moral consciousness on which stress is laid in Theistic arguments (a) The authority which the conscience attributes to the moral ideal This unique authority cannot, it is urged, be explained on any view which does not allow us to find the moral law in some way built into the structure of the world, grounded in Reality Other possible accounts of the source of the sense of obligation really issue in an explaining away of the moral "ought," and hence in the consequence that the fully moral life is irrational Further, it is urged, the Theistic view is the view which most clearly enables us to hold that the moral law is not simply imposed externally but is the expression of the deepest self and also that it is no mere individual product, but of universal validity. (b) The "objectivity" of the moral ideal The conscience cannot be satisfied with the belief that the moral ideal is dependent upon opinion, whether of the individual or of groups. In spite of the obvious fact that moral ideas change, the moral life depends upon the conviction that the moral ideal itself is absolute Though men's apprehension of it may grow, their apprehension does not create it It may be argued that Theism gives us the most rational account of this aspect of the moral consciousness, since it suggests that the moral ideal may exist in the thought of God (c) The content of the moral ideal, particularly when viewed in its social aspect. Though we know what we mean by progress, we cannot conceive any temporal condition which would be the final goal of social progress Unless therefore we are prepared to allow that progress is towards an end which is inherently unattainable, we are led to the thought of an End which is beyond the temporal order Here again the

theistic hypothesis appears to offer the most reasonable view, since it would hold that perfect communion with God and herein with all rational beings, is the nature of the highest Good. The central thought of the moral argument in all its forms is this: given man's moral experience at its highest we have the choice of regarding it as rational and significant, or of explaining it away as partially founded on a mistake with the probable consequence of weakening its effectiveness. If we choose to regard it as rational and significant Theism is the view of the world which will most adequately fulfil our demands

The Argument from Values in General.—Strictly speaking the moral argument is a special case of the line of reasoning which sets out from the existence of values. The world manifests the character of having value, or of being the occasion of our apprehension of value. Truth, goodness and beauty are real in our experience. In every case however, we are led to the conception of an absolute value, a complete Truth, a perfect Good and Beauty The very fact that we recognise degrees of truth, goodness and beauty, implies that we tacitly presuppose an absolute standard towards which the partial values which we enjoy are approximations Nor again, can we suppose that in the end these values are opposed to one another, though in finite experience they may sometimes seem to conflict. On the contrary, the Ultimate values must form a Unity, or rather perhaps, be aspects or attributes of one Supreme Value, which is what we mean by God This is the line of thought which carries on the Platonist tradition in Christian philosophy and is impressively stated by Dr. W R Inge in his *Philosophy of Plotinus* and other writings

Religious Experience.—Among the ancient arguments for Theism should be enumerated the argument *e consensu Gentium,* from the agreement of the nations. The evidence to be derived from the fact that all men everywhere believed in the Divine was insisted on by the Stoics and has been held to show that the idea of God is "innate" in the human mind. Precisely in this form the reasoning is open to objection. Locke, in his polemic against "innate ideas" in general, pointed out that the argument collapsed when we asked, what idea of God is innate? for the conceptions of the divine held by savages differ profoundly from those of civilized nations. The study of Comparative Religions since the time of Locke has served to support in detail his contention; but on the other hand it has shown that religion is practically a universal phenomenon wherever the human race is found. A new and more profound approach to Theism, which has some affinity with the old argument *e consensu Gentium,* has been opened by this enlarged knowledge. It is now possible to study the religious experience of mankind as a whole. When this is done we can discern an upward movement of the experience and of the concepts of the Divine in which it finds expression This upward movement does not take place over the whole field, but certain principles of development may be noticed which are fully exemplified only where the religious impulse has free course. The primitive ideas of animism and polydaemonism, give place to polytheism, which in turn is displaced by monotheism either in the form of pantheism or ethical monotheism. It is always open to the critic to dismiss the whole religious experience of humanity as based on illusion and mistake; but such a drastic rejection of a universal type of consciousness is hard to justify If we base our knowledge of the Universe on experience, religious experience has a claim to be included. If further, we find that the religious experience tends to pass from obviously inadequate forms to forms which lend themselves to rational presentation, we shall be justified in regarding the later and higher as the nearest approximations so far to adequate discriminations of the Object with which all religious experience is concerned.

Parallel to this consideration of the general development of religious experience runs the evidence to be derived from a study of the great religious personalities, and particularly of the mystics. The mystical type of religious "genius" seems to enjoy an immediate contact with the Divine, and the statements made by such persons have some general agreement. Too much stress should not be laid on their testimony to the truth of Theism, since some of the evidence would support Pantheism rather than Theism, and there is a tendency among mystics to interpret their experience in terms of the religious imagery in which they have been brought up The witness of the mystics to the supernatural is impressive, and they may be linked with the general argument from religious experience as salient instances of its power at every level It is urged by several Christian writers that the definitely Theistic mysticism of the Christian mystics is a higher and more complete type of mysticism than any other (*See*, for example, W R Inge, *Christian Mysticism,* E. Underhill, *Mysticism,* and R Otto, *West Östliche Mystik*)

In concluding this summary of grounds of Theistic belief we must remark again that few philosophical Theists would rest their case on a direct demonstration or claim that they were in possession of an "apodeictic" argument; they would urge that the full force of the reasons in favour of Theism can only be appreciated when it is compared with other possible views of the Universe, and that several converging lines of thought form a cumulative argument which is difficult to resist

SOME PROBLEMS OF THEISM

The Theistic view of the world is naturally impelled to articulate itself by considering the problems of the nature of God and His relations with the world Some of the more important of these problems must now be briefly indicated.

Divine Personality.—Most Theists, if not all, would agree that God is, in some sense, personal, or at least not of a nature inferior to personality The latter tenet seems to be implied in the Theistic hypothesis, for otherwise God could not be thought of as the Supreme Value It is important however, to distinguish between the two propositions, "God is personal" and "God is a person." Though the second of these propositions has been held by many Theists, it is not an essential point Orthodox Christianity cannot be cited on behalf of the belief that God is a person, for the doctrine of the Trinity would suggest that the Godhead is a Unity of Persons. No one, of course, would maintain that God is a person in precisely the same sense as human beings are persons, and in view of this some would prefer to speak of the Divine Nature as Supra-Personal, others, on the contrary, as for example Lotze, would hold that God alone is the perfect person and that finite selves are "pale shadows" of His personality No very vital principle is involved in this difference, so long as those who prefer the term "supra-personal" are clear that it is not a polite phrase for "impersonal" Theistic religion is profoundly concerned to maintain that God is a being with whom personal relations are possible; if that be abandoned we shall be compelled to dismiss that religious experience, which Theists take to be the highest and most significant, as illusion The main theoretical ground for accepting Divine Personality is the contention that personality is the highest type of existence known to us, the "bearer," the discerner, and the creator of values, and also that personal life is the most conspicuous instance of multiplicity in unity, it is, as Plotinus called it, a πλῆθος ἕν : the category of personality would appear, in its ideal form, to suggest an ultimate solution of the problem of the One and the Many A difficulty has been raised concerning the attribution of personality to God on account of the alleged necessity of a "not-self" distinguishable from the self in all cases of self-consciousness. The discussion of this problem by Lotze in his *Microcosmus* (Bk. IX , Chap. IV), remains the classical authority It is noteworthy however, that this special difficulty does not press with such force upon the Trinitarian form of Theism. On any Theistic view it would appear that the created order must be in some sense a "not-self" with respect to God, since the identification of the created order with the Being of God would be Pantheism

Divine Attributes.—The Theistic doctrine of God has usually included an account of the Divine Nature under the title of "attributes," but the error must be carefully guarded against of conceiving the Divine Nature as the sum of the Divine Attributes They are rather different aspects from which the Divine Being may be viewed by us. The traditional division is into Metaphysical and Moral The Scholastic Theology considered the Metaphysical Attributes to be those which refer to God as He is in

Himself and the Moral Attributes those which refer to Him in relation with the world. It may be questioned however, whether the human mind is capable of having knowledge of God of that absolute character suggested by this definition of the Metaphysical Attributes. If the division be retained it is perhaps better to say simply that by Metaphysical Attributes we mean those which have a primarily intellectual importance, such as Unity and Infinity, while by Moral we mean those which have a directly practical bearing, such as Righteousness and Love. The classification, however, is of doubtful value, since even the attributes which are most evidently "metaphysical" have profound religious results, and those which are "moral" have metaphysical import.

Reflection upon the Being of God has followed along two paths—the *via negativa,* and the *via eminentiae.* The first of these methods turns on the conception of God as the Infinite and works with a negative conception of infinity. God, being infinite, cannot be described by any predicates which would imply limitation. All positive assertions, however, imply such a limitation It follows therefore that no positive quality can be affirmed of God, not even goodness or indeed even being, so that if we say that God is τὸ ὄν we must also say that He is equally τὸ μὴ ὄν. Clearly this method leads to a position which is hardly distinguishable from Agnosticism. The *via eminentiae* starts with the conception of God as the Ground and Source of all existence and with the postulate that the Ground must be adequate to the consequences. All positive qualities, therefore, which occur in created existence must be ascribed to God; but plainly not *"simpliciter";* they are, so to speak, raised to infinity. Knowledge is in God Omniscience, Will Omnipotence, Beauty perfect Loveliness. We must observe here that the *via eminentiae* really implies the view that evil is not positive being but privation or defect of being, a view which was held by Augustine and Aquinas; for if evil were a positive existence or quality of existence the argument of the *via eminentiae* would lead us to predicate evil of God.

The Divine Attributes have been the subject of much subtle and intricate speculation into which it is impossible to enter here Brief remarks on two must be made, since they are of great importance in Theistic theory Omniscience is the perfection of that quality of knowledge which is found imperfectly in some created beings Evidently the Divine knowledge cannot suffer from the imperfections of human knowing It is scarcely appropriate to imagine the Divine Intelligence engaged in "discursive" thought and pursuing trains of reasoning The most adequate human knowledge is that described by Spinoza as *scientia intuitiva,* intuitive knowledge in which grounds and conclusion are apprehended in one intellectual act. Of this kind, it would seem, the Divine knowledge must be. We are brought here to the recognition of one aspect of the Divine Infinity and Eternity Human knowing is a part of a temporal experience and therefore itself a temporal process. The Divine experience and knowledge cannot be temporal, or at least cannot be "in time." A recognition of this truth has important bearing on some of the puzzles of Christian and other Theologies connected with the Divine Foreknowledge If the Divine Experience is not successive but simultaneous, the expression "foreknowledge" is evidently misleading and indicates that in presenting to ourselves the Divine Nature and Experience we are compelled to make use of inadequate concepts derived from our own experience, and hence to encounter problems which are insoluble because we have not the terms in which to state them accurately.

The same remarks apply to the attribute of Omnipotence in which we attempt to indicate the nature of the Divine Will. Clearly a supra-temporal will is beyond our powers of adequate conception. This does not prove, as Spinoza held, that will is absent from God's experience, but it certainly shows that we cannot transfer ideas derived from our experience of finite acts of will directly to the Divine Will. The conception of Omnipotence gives rise to problems which are, in their nature, not completely soluble by human reason. Two possible meanings of the word have been suggested It has been held, on the one hand, that omnipotence implies not only the power to do all that is possible but also that the determination of the possible is due to the will of God, so that the fundamental laws of thought and of morality are fiats of the Divine Will and not limitations upon it. On the other hand, it is held that the will of God is determined by the principles of reason and goodness which are inherent in His Nature and that omnipotence means the power to do all that is possible. Of these two views the latter is to be preferred, since the former asks us to conceive of the Divine Will as arbitrary and not in any intelligible sense either rational or good. Even so, however, it cannot be pretended that all difficulty has been removed from the conception of omnipotence, and we may perhaps be content to say, with Schleiermacher, that both omnipotence and omniscience are ways of expressing the fundamental conviction of Theism that all things ultimately depend upon God.

Creation and Self-limitation.—Theism does not identify God and the world. It maintains indeed that God is immanent in creation but also transcendent, and it holds therefore that there is a real distinction between God and the world. This distinction is expressed in the idea of Creation. Theism on the whole has preferred the idea of creation to that of emanation, which is the idea adopted by systems which lead to Pantheism. Emanation implies that the world proceeds from the Divine Being by a kind of necessary process, a common figure being that of the sun and its rays. Creation, on the other hand, emphasizes the factor of will and implies that the world exists as a result of an act of choice. Creation does not necessarily involve a belief that the world began at a definite moment of time or that the creative act of God is single; it is perfectly compatible with the belief in a continuous creation which would be in harmony with modern theories of evolution.

Any belief in creation, and indeed any belief in the reality of freedom, seems clearly to necessitate some limitation of the omnipotence and perhaps of the omniscience of God. At the same time, Theism cannot admit that any portion of existence is absolutely independent of God. To meet this dilemma the thought of a divine "self-limitation" has been employed. Admittedly this is a thought which cannot be articulated in any detail We cannot know the conditions of such self-limitation. But the conception itself is required by the facts as they appear in religious and moral experience. We may urge that the idea is not really contradictory of omnipotence, for an omnipotence which could not limit itself would not be omnipotent And there is no inherent difficulty in the moral attributes of God, for it may be argued that the development of free moral persons who can enter into communion with God is the ultimate purpose of creation, and that this end could not be attained apart from a limitation of the divine power which makes freedom possible and with it both moral good and moral disaster.

A difference of opinion among Theists exists on the question whether creation is in any sense necessary to God On this point traditional Christian theology and some modern idealistic interpretations of Christianity (*e.g.,* Hegel's) are at variance. Christian theology on the whole has laid down that the world is in no way necessary to God and that its creation does not add to His perfection or satisfaction. The opposite view, which emphasises the Divine immanence, holds that the world is as necessary to God as God to the world. A distinction should be made between the active and passive sense of "creation." Thus it might be conceived that creation is an essential attribute of God and at the same time that the present universe is not necessary to God, that to create is an eternal activity of God but no product of that activity is eternal. A theory of this kind would avoid the difficulties which arise when we attempt to conceive a beginning of creation. (On this point *see* further, *Studies in Christian Philosophy* by W R. Matthews.)

A problem in Theistic philosophy closely connected with the foregoing is that of the place of suffering in the Divine Experience. Here again the weight of Christian thought is against the admission of anything which would seem to qualify the absolute self-sufficiency and perfection of the Divine Nature. Suffering arises through frustration and limitation, conditions which are hardly to be thought of in connection with the Supreme Being. Against this may be set some considerations arising from the problem of evil

and the moral perfection which we believe God to possess. It would seem difficult to think of Divine Sympathy with suffering if suffering could not enter into the Divine Experience; and it would seem strange to ascribe moral perfection to God if self-sacrifice, which involves voluntary pain, were excluded. On these grounds many writers on Theism and Christian Theologians in the present century have argued that suffering must enter into the Divine Consciousness, and some have urged that this is really an essential element in the Christian view of the world. (For a survey of opinion on this subject *see* J. K. Mozley, *The Impassibility of God.*) It must be observed, however, that Theism could not admit that suffering is the dominant note of the Divine Experience. To do so would be to fall back upon the conception of a "God" so limited and struggling that He may be ultimately defeated. Our experience, however, offers us an analogy which throws light upon the problem At the highest level of spiritual life a condition of "blessedness" has sometimes been attained which is far different from a condition of mere pleasure and absence of pain. Pain enters into it as an essential element, but the condition itself is not one of pain, rather it is one in which the self finds its truest satisfaction and which it would not exchange for any maximum of pleasant feeling. Of this kind, though in an infinitely higher degree, we may imagine the life of God to be.

THEISS: *see* Tisa

THELEPTE, an ancient Roman city in western Tunisia, 35 m. S.W. of Sufetula (Sbeitla), 2,650 ft. above sea-level. The ruins are extensive, but most of the buildings are almost entirely destroyed, and only their ground plan can be recognized. To the south-west are some massive remains of baths.

THEMIS. (1) An ancient goddess, often identified with Ge, said to have been the occupier of Delphi in days before Apollo (*see* Oracles). She is the mother of Prometheus (*q.v.*). (2) A goddess of justice (*cf.* Nemesis). In Homer θέμις is used both as a common noun (doom, decree; *cf.* Greek Law) and as a proper name; Themis is the servant or companion of Zeus, her chief function being to summon the assemblies of both gods and men (*Odyssey*, ii. 68). In the Hesiodic theogony, she is the daughter of Uranus and Ge, and according to Pindar the wife of Zeus, by whose side she sits, assisting him with her advice, which is even better than that of any of the gods. She is the mother of the Horae and of the Fates (*q.v.*). Her opposite is Hybris (ὕβρις), insolent encroachment upon the rights of others. The exact relation between (1) and (2), save that they have in common the idea of stability (θέμις, root θε, place) is obscure. Orphic poetry makes her a daughter of Helios.

See R. Hirzel, *Themis, Dike, und Verwandtes* (1907); L. Weniger in Roscher's *Lexikon, s.v.* (bibliography).

THEMISTIUS (317–?387), named εὐφραδής ("eloquent"), statesman, rhetorician and philosopher, was born in Paphlagonia and taught at Constantinople, where, apart from a short sojourn in Rome, he resided during the rest of his life. Though a pagan, he was admitted to the senate by Constantius in 355. He was prefect of Constantinople in 384 on the nomination of Theodosius. His paraphrases of Aristotle's *Posterior Analytics, Physics* and *De Anima* are valuable; but the orations in which he panegyrizes successive emperors, comparing them to Plato's "true philosopher," and even to the "idea" itself, are servile and unworthy. Themistius's paraphrases of the *De Coelo* and of book Λ of the *Metaphysics* have reached us only through Hebrew versions. In philosophy Themistius was an eclectic.

See E. Zeller, *Philosophie der Griechen* (1881). *See* also H. Schenkl, *Beiträge zur Textgeschichte der Reden des Themistios* (Vienna, 1919).

THEMISTOCLES (*c.* 514–449 B.C.), Athenian soldier and statesman in some respects probably the ablest and most far-sighted whom Greece produced in the first half of the 5th century. He was the son of Neocles, an Athenian of no distinction and moderate means, his mother being a Carian or a Thracian. Hence according to the Periclean law ἐξ ἀμφοῖν ἀστοῖν he would not have been a free Athenian at all (*see* Pericles). Thucydides observes that, though he lacked the culture typical of the Periclean age, he displayed a marvellous power of analysing a complex situation together with a genius for rapid action. Plutarch similarly enlarges on his consuming ambition for power both personal and national, and the unscrupulous ability with which he pursued his ends. Of his early years little is known. He may have been strategus of his tribe at Marathon.

At all events the death of Miltiades left the stage to Aristeides and Themistocles. It is sufficiently clear that their rivalry turned largely on the fact that Themistocles was the advocate of a policy of naval expansion. This policy was unquestionably of the highest importance to Athens and indeed to Greece. Athens was faced by the equal if not superior power of Aegina, while the danger of a renewed Persian invasion loomed large. Themistocles persuaded his countrymen to put in hand the building of 200 triremes, and to fortify the three natural harbours of Peiraceus (*see* E. Gardner, *Ancient Athens*, 562 f.) in place of the open roadstead of Phalerum. For the building of the ships Themistocles persuaded the Athenians to allocate 100 talents obtained from the new silver mines at Laureium (*Ath. Pol.* 22) which were about to be distributed to the citizens (10 drachmae each). One hundred of the proposed 200 were built.

He may or may not have been archon in 483, according to the *Ath. Pol.*, when this programme began. Dionysius of Halicarnassus places his archonship in 493–92, in favour of which are several considerations. In 487 the office lost much of its importance owing to the substitution of the lot for the election; the chance that the lot would at the particular crisis of 483 fall on Themistocles was obviously remote. In any case, the chief men of the other side disappear one by one—culminating in the ostracism of Aristeides in 482, and the year prior to the invasion of Xerxes found Themistocles the chief man in Athens if not in Greece. Though the Greek fleet was nominally under the control of the Spartan Eurybiades, it was Themistocles who forced the indecisive battle of Artemisium, and by his threat that he would lead the Athenian army to found a new home in the West, and by his treacherous message to Xerxes, precipitated the engagement at Salamis (*see* P. W. Dodd in *Class. Rev.* 27, p. 117). The retirement of the Persians left the Athenians free to restore their ruined city (*see* Athens). Sparta opposed the rebuilding of the walls, but Themistocles by a subterfuge got the walls built high enough to be defensible. He also carried out his original plan of making Peiraceus a harbour and fortress for Athens. Athens thus became the finest trade centre in Greece, and this fact, coupled with Themistocles' remission of the alien's tax (μετοίκιον) induced many foreign business men to settle in Athens.

After the crisis of the Persian invasion Themistocles and Aristeides appear to have composed their differences. But Themistocles soon began to lose the confidence of the people, partly owing to his boastfulness (it is said that he built near his own house a sanctuary to Artemis Aristoboulē "of good counsel") and partly to his alleged readiness to take bribes. Diodorus (xi. 54) and Plutarch (*Themist.* 23) both refer to some accusation levelled against him. There is, however, much difficulty regarding this accusation; it may be simply a misunderstanding of his ostracism. Some time between 476 and 471 he was ostracized. He took refuge eventually in Asia Minor, and was proclaimed a traitor in Athens. He was well received by the Persians and was allowed to settle in Magnesia on the Maeander. He died at Magnesia at the age of 65, and a splendid memorial was raised by the people of the town, though it is said that his bones were secretly transferred to Attica. He was worshipped by the Magnesians as a god, as we find from a coin on which he is shown with a patera in his hand and a slain bull at his feet (hence perhaps the legend that he died from drinking bull's blood: *cf.* Aristoph. *eq.* 83;

Diod xi. 58; Plut. *Them.* 31).

Though his end was discreditable, though his great wealth can hardly have been obtained by loyal public service, there is no doubt that his services to Athens and to Greece were great. He created the Athenian fleet and with it the possibility of the Delian League (*q v*) which became the Athenian empire, and there are many indications (*e g.*, his well-attested plan of expansion in the west) that the later imperialist ideal originated in his fertile brain

THÉNARD, LOUIS JACQUES (1777–1857), French chemist, was born on May 4, 1777, at Louptière (Aube), the son of a poor peasant, who made great sacrifices for his son's education. He worked in a humble capacity in the laboratory of L N Vauquelin, who procured for him various teaching posts In 1804, when Vauquelin retired from the chair of chemistry at the Collège de France, he used his influence to secure Thénard's succession to the post Later, Thénard held the chair of chemistry at the Ecole Polytechnique and at the Sorbonne He was a member of the Academy, a peer of France (1832), deputy for Yonne (1827–30), and a member of the council of education. He died in Paris on June 21, 1857, and the name of his native village was changed (1865) to Louptière-Thénard in his honour.

Thénard was a great teacher, and his *Traité de chimie élémentaire* (4 vols, 1813–16), which was the standard text-book for a quarter of a century, did more, perhaps, than even his many important original discoveries to advance the cause of science With his lifelong friend, Gay-Lussac (*q v*), he carried out many researches His researches on esters (1807), sebacic acid (1802) and on bile (1807), his discovery of peroxide of hydrogen (1818) and his work on organic phosphorus compounds (1846) deserve mention The substance known as "Thénard's blue," he prepared in 1799 in response to a peremptory demand by J. A Chaptal for a cheap colouring matter, as bright as ultramarine and capable of standing the heat of the porcelain furnace

A list of Thénard's memoirs may be found in the Royal Society's *Catalogue of Scientific Papers*

THEOBALD (d 1161), archbishop of Canterbury, was of Norman parentage, but the date of his birth is unknown Early in life he entered the abbey of Bec, of which he became prior in 1127 and abbot ten years later. In 1138 he was elected to the see of Canterbury, and as archbishop he behaved with a moderation which is in striking contrast to the conduct of his rival, Henry of Blois, bishop of Winchester During the struggle between Stephen and Matilda it was Bishop Henry who fought for the privileges of the Church; Theobald, while showing a preference for Stephen's title, made it his rule to support the *de facto* sovereign But as Stephen's cause gained ground the archbishop showed greater independence. He refused to consecrate the king's nephew to the see of York, and in 1148 attended the papal council of Reims in defiance of a royal prohibition. This quarrel was ended by the intercession of the queen, Matilda of Boulogne, but another, of a more serious character, was provoked by Theobald's refusal to crown Count Eustace, the eldest son of Stephen, the archbishop pleading the pope's orders as the excuse for this contumacy In 1153 Theobald succeeded in reconciling Stephen with Henry of Anjou, and in securing for the latter the succession to the throne. He placed the interests of the Church in the hands of Thomas Becket, his archdeacon. Theobald died on April 18, 1161.

In history Theobald lives chiefly as the patron of three eminent men: Becket, who began life as a clerk in his household; Master Vacarius, the Italian jurist, who was the first to teach Roman law in England; and John of Salisbury, the learned scholar. Theobald's household was a university in little; and in it were trained many leading prelates of the next generation.

See the *Vita Theobaldi* printed in J. A Giles, *Lanfranci Opera*, vol. i. (Oxford, 1844); W. Hook, *Lives of the Archbishops of Canterbury*, ii. c. vi (London, 1862); and K Norgate, *England under the Angevin Kings*, vol. i. (London, 1887). (H. W. C. D)

THEOBALD, LEWIS (1688–1744), English man of letters, playwright and Shakespearian commentator, the son of an attorney, was born at Sittingbourne, Kent. He was baptized on April 2, 1688, and was educated for the law. He translated the *Phaedo* of Plato in 1713, in 1714–15 the plays of Sophocles and of Aristophanes, and in 1716 the first book of the *Odyssey*. Meanwhile he had got into trouble in 1716 on a charge of plagiarism in his play *The Perfidious Brother*. But Theobald is remembered neither as translator, nor as original author, but for his work on the text of the Shakespeare plays.

In 1726 he produced *Shakespeare Restored, or a Specimen of the many Errors as well Committed as Unamended by Mr. Pope in his late edition of this Poet; designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever published* (1726). Some of his happiest emendations are to be found in this work, which conclusively proved Pope's incompetence as a Shakespearian editor

In 1731 Theobald undertook to edit Shakespeare for Tonson the publisher The work appeared in seven volumes in 1734, and completely superseded Pope's edition. Subsequent editors reaped, in many cases without acknowledgment or with actual scorn, the fruit of Theobald's painstaking labour, his wide learning and his critical genius.

His correspondence with Matthew Concanen, Styan Thirlby and William Warburton is to be found in Nichols's *Illustrations of Literature* (ii 204–654), which also gives the fullest account of his life *See* also R. F Jones, *Lewis Theobald, his contribution to English Scholarship* (N Y. 1919).

THEOCRITUS, the creator of pastoral poetry, flourished in the 3rd century B C. Little is known of him beyond what can be inferred from his writings We must, however, handle these with some caution, since some of the poems ("Idylls") commonly attributed to him have little claim to authenticity It is clear that at a very early date two collections were made, one of which included a number of doubtful poems and formed a *corpus* of bucolic poetry, while the other was confined to those works which were considered to be by Theocritus himself The record of these recensions is preserved by two epigrams, one of which proceeds from Artemidorus, a grammarian, who lived in the time of Sulla and is said to have been the first editor of these poems He says, "Bucolic muses, once were ye scattered, but now one byre, one herd is yours" The second epigram is anonymous, and runs as follows —"The Chian is another. I, Theocritus, who wrote these songs, am of Syracuse, a man of the people, the son of Praxagoras and famed Philina. I never sought after a strange muse" The last line may mean that he wrote nothing but bucolic poems, or that he only wrote in Doric The statement that he was a Syracusan is confirmed by allusions in the "Idylls" (xi 7, xxviii 16–18). A larger collection, possibly more extensive than that of Artemidorus, and including poems of doubtful authenticity, was known to Suidas, who says. "Theocritus wrote the so-called bucolic poems in the Dorian dialect. Some persons also attribute to him the following. *Daughters of Proetus, Hopes, Hymns, Heroines, Dirges, Lyrics, Elegies, Iambics, Epigrams*" The first of these may have been known to Virgil, who refers to the *Proetides* in the *Eclogues* (*Ecl.* vi., 48). The spurious poem xxi may have been one of the *Hopes* (*cf.* 1 66, ἐλπὶς τῶν ὕπνων), and poem xxvi may have been one of the *Heroines* (*cf.* 1 36, ἡρωῖναι): elegiacs are found in viii. 33–60, and the spurious epitaph on Bion may have been one of the *Dirges*. The other classes are all represented in the larger collection which has come down to us

The poems which are generally held to be authentic may be classified thus.—

I. Bucolics and Mimes.—The distinction between these is that the scenes of the former are laid in the country and those of the latter in a town. The most famous of the *Bucolics* are i., vii, xi. and vi. In i. Thyrsis sings to a goatherd how Daphnis, the mythical herdsman, having defied the power of Aphrodite, dies rather than yield to a passion with which the goddess had

inspired him. In xi. Polyphemus is depicted as in love with the sea-nymph Galatea and finding solace in song. in vi. he is cured of his passion and naively relates how he repulses the overtures now made to him by Galatea. The monster of the *Odyssey* has been "written up to date" after the Alexandrian manner and has become a gentle simpleton. Idyll vii., the "Harvest Feast" (Θαλύσια), is the most important of the bucolic poems The scene is laid in the isle of Cos The poet speaks in the first person and is styled Simichidas by his friends Other poets are introduced under feigned names Thus ancient critics identified Sicelidas of Samos (l. 40) with Asclepiades the Samian, and Lycidas, "the goatherd of Cydonia," may well be the poet Astacides, whom Callimachus calls "the Cretan, the goatherd" Theocritus speaks of himself as having already gained fame, and says that his lays have been brought by report even unto the throne of Zeus (possibly Ptolemy: *cf.* Horace, *Ep.* i. 19, 43, *Iovis auribus ista Servas,* where *Iuppiter*=Augustus). He praises Philetas, the veteran poet of Cos, and criticizes "the fledgelings of the Muse, who cackle against the Chian bard and find their labour lost"

The other bucolic poems need not be further discussed Several of them consist of a singing-match, conducted according to the rules of amoebean poetry, in which the second singer takes the subject chosen by the first and contributes a variation in the same air It may be noted that the peasants of Theocritus differ greatly in refinement Those in v. are low fellows who indulge in coarse abuse. This Idyll and iv are laid in the neighbourhood of Croton, and we may infer that Theocritus was personally acquainted with Magna Graecia Suspicion has been cast upon poems viii. and ix. on various grounds An extreme view holds that in ix. we have two genuine Theocritean fragments, ll 7–13 and 15–20, describing the joys of summer and winter respectively, which have been provided with a clumsy preface, ll 1–6, while an early editor of a bucolic collection has appended an epilogue in which he takes leave of the Bucolic Muses On the other hand, it is clear that both poems were in Virgil's Theocritus, and that they passed the scrutiny of the editor who formed the short collection of Theocritean Bucolics

The mimes are three in number, viz, ii, xiv, xv. In ii. Simaetha, deserted by Delphis, tells the story of her love to the moon; in xiv. Aeschines narrates his quarrel with his sweetheart, and is advised to go to Egypt and enlist in the army of Ptolemy Philadelphus; in xv Gorgo and Praxinoe go to the festival of Adonis. It may be noticed that in the best mss. ii comes immediately before xiv, an arrangement which is obviously right, since it places the three mimes together. The second place in the mss. is occupied by Idyll vii, the "Harvest Feast" These three mimes are wonderfully natural and lifelike. There is nothing in ancient literature so vivid and real as the chatter of Gorgo and Praxinoë, and the *voces populi* in xv

It will be convenient to add to the *Bucolics* and *Mimes* three poems which cannot be brought into any other class, viz., xii. (Ἀΐτης), a poem to a beautiful youth, xviii., the marriage-song of Helen (Ἐπιθαλάμιος); and xxvi, the murder of Pentheus (Λῆναι). The genuineness of the last has been attacked by U. von Wilamowitz-Mollendorff on account of the crudity of the language, which sometimes degenerates into doggerel It is, however, likely that Theocritus intentionally used realistic language for the sake of dramatic effect, and the mss evidence is in favour of the poem Eustathius quotes from it as the work of Theocritus.

II. Epics.—Three of these are Hymns, viz, xvi, xvii and xxii. In xvi. the poet praises Hieron II of Syracuse, in xvii Ptolemy Philadelphus, and in xxii the Dioscuri The other poems are xiii, the story of Hylas and the Nymphs, and xxiv. the youthful Heracles. It cannot be said that Theocritus exhibits signal merit in his *Epics.* In xiii. he shows some skill in word-painting, in xvi. there is some delicate fancy in the description of his poems as "Graces" (Χάριτες), and a passage at the end, where he foretells the joys of peace after the enemy have been driven out of Sicily, has the true bucolic ring. The most that can be said of xxii. and xxiv. is that they are very dramatic. Otherwise they differ little from work done by other poets, such as Callimachus and Apollonius Rhodius. The flattery heaped upon Ptolemy is somewhat nauseous. From another point of view, however, these two poems xvi. and xvii. are supremely interesting, since they are the only ones which can be dated In xvii Theocritus celebrates the incestuous marriage of Ptolemy Philadelphus with his sister Arsinoë This marriage is held to have taken place in 277 B.C, and Arsinoë died in 270. This poem, therefore, together with poem xv., which Theocritus wrote to please Queen Arsinoë (*Schol.* χαριζόμενος τῇ βασιλίδι) must fall within this period. The encomium upon Hiero II would from internal reasons seem prior to that upon Ptolemy, since in it Theocritus is a hungry poet seeking for a patron, while in the other he is well satisfied with the world. Now Hieron first came to the front in 275 B.C. when he was made "General" (στρατηγός): Theocritus speaks of his achievements as still to come, l. 73, and the silence of the poet would show that Hieron's marriage to Philistis, his victory over the Mamertimes at the Longanus and his election as "King" (βασιλεύς), events which are ascribed to 270 B C, had not yet taken place. If so, xvii and xv. can only have been written within 275 and 270.

III. Lyrics.—Two of these are certainly by Theocritus, viz, xxviii. and xxix. The first is a very graceful poem presented together with a distaff to Theugenis, wife of Nicias, a doctor of Miletus, on the occasion of a voyage thither undertaken by the poet. The theme of xxix is similar to that of xii A very corrupt poem, only found in one very late ms, was discovered by Ziegler in 1864 As the subject and style very closely resemble that of xxix, it is assigned to Theocritus by recent editors.

IV. The Epigrams.—These do not call for detailed notice. They do not possess any special merit, and their authenticity is often doubtful It remains to notice the poems which are now generally considered to be spurious They are as follows:—

xix "Love stealing Honey" (Κηριοκλέπτης). The poem is anonymous in the mss. and the conception of Love is not Theocritean.

xx. "Herdsman" (Βουκολίσκος), xxi. "Fishermen" (Ἁλιεῖς), xxiii "Passionate Lover" (Ἐραστής). These three poems are remarkable for the corrupt state of their text, which makes it likely that they have come from the same source and possibly are by the same author The "Fishermen" has been much admired It is addressed to Diophantus and conveys a moral, that one should work and not dream, illustrated by the story of an old fisherman who dreams that he has caught a fish of gold and narrates his vision to his mate. As Leonidas of Tarentum wrote epigrams on fishermen, and one of them is a dedication of his tackle to Poseidon by Diophantus, the fisher (*Anth Pal* vi 4, 7), it is likely that the author of this poem was an imitator of Leonidas. It can hardly be by Leonidas himself, who was a contemporary of Theocritus, as it bears marks of lateness

xxv. "Heracles the Lion-slayer" (Λεοντοφόνος). This is a long poem consisting of two episodes, viz, the interview of Heracles with the bailiff of Augeas and his recital to Phyleus, son of Augeas, of the story of the Nemean lion. The composition is not unworthy of Theocritus. It is, however, anonymous in the mss and comes next to another anonymous poem called "Megara, the wife of Hercules." It is probable from some metrical and linguistic peculiarities that xxv and the "Megara" are by the same author

xxvii. "The wooing of Daphnis" (Ὀαριστύς) is also anonymous It contains imitations of Theocritus, but the tone and the language betray a later writer.

We have no sure facts as to the life of Theocritus beyond those supplied by Idylls xvi. and xvii It is quite uncertain whether the bucolic poems were written in the pleasant isle of Cos among a circle of poets and students, or in Alexandria and meant for dwellers in streets. The usual view is that Theocritus went first from Syracuse to Cos, and then, after suing in vain for the favour of Hiero, took up his residence permanently in Egypt. Some have supposed on very flimsy evidence that he quarrelled with the Egyptian court and retired to Cos, and would assign various poems to the "later-Coan" period. Wilamowitz-Möllendorff, laying stress on the fact that in the best ms the poem to Ptolemy (xvii) comes before that to Hieron (xvi.), puts the Egyptian period first and supposes it to have been of very short duration (*i e*, 277 to 275), and then makes the poet, after his unsuccess-

ful appeal to Hieron, retire to Cos for the rest of his life. This view would enable us to see a reference to Ptolemy in vii 93, and even to Apollonius Rhodius in 47–48 of the same poem.

The poems of Theocritus were termed *Idylls* (εἰδύλλια), by the grammarians The word is a diminutive from εἶδος, and is supposed to mean "little poems." The use of εἶδος in the sense of "poem" is somewhat doubtful, and so some have referred εἰδύλλια to εἶδος in its usual sense of "form" or "type." Thus εἶδος βουκολικόν, ἐπικόν, λυρικόν might be used to classify various kinds of poetry, and these poems might be called εἰδύλλια, since they include so many types

Language and Metre.—Theocritus wrote in various dialects according to the subject. The Lyrics xxviii., xxix (and xxx) are in Aeolic, that being the traditional dialect for such poems Two poems, xii (Ἀΐτης) and xxii. ("To Castor and Pollux"), were written in Ionic, as is stated in titles prefixed to them, though a number of Doric forms have been inserted by the scribes The epics in general show a mixture of Homeric, Ionic and Doric forms The *Bucolics*, *Mimes*, and the "Marriage-song of Helen" (xviii) are in Doric, with occasional forms from other dialects

The metre used by Theocritus in the *Bucolics* and *Mimes*, as well as in the *Epics*, is the dactylic hexameter A feature in his versification which has attracted much attention is the so-called bucolic caesura The rule is that, if there is a pause at the end of the fourth foot, this foot must be a dactyl This pause is no new invention, being exceedingly common in Homer Theocritus uses it so frequently in the *Bucolics* that it has become a mannerism. In the *Epics* his practice agrees with that of Homer

We always think of Theocritus as an original poet, and as the "inventor of bucolic poetry" he deserves this reputation At the same time he had no scruple about borrowing from predecessors or contemporaries; in fact he did so in the most open manner. Thus xxix begins with a line of Alcaeus, and xvii , as the Scholiast points out, with words used by Aratus at the beginning of the *Phenomena* The love of the Cyclops for Galatea had been treated by Philoxenus, and fragments quoted from this show that Theocritus copied some of his phrases closely. In the mimes Theocritus appears to have made great use of Sophron Idyll ii is modelled upon a mime of this writer which began in a very similar way The Scholiast thought that Theocritus showed want of taste in making Thestylis a *persona muta,* instead of giving her a share in the dialogue as Sophron had done The famous poem about Gorgo and Praxinoe at the feast of Adonis was modelled on one by Sophron about women looking on at the Isthmian games (Ἰσθμιάζουσαι), and fragments quoted from this are closely imitated by Theocritus It is extremely interesting to find a similar poem in the recently discovered mimes of Herondas, the fourth of which is termed "Women making offerings to Aesculapius" (Ἀσκληπιῷ ἀνατιθεῖσαι καὶ θυσιάζουσαι). The relation of Theocritus to Herondas is a subject of great interest Herondas must have been a contemporary, as he refers to Ptolemy Philadelphus (l. 30) and was a native of Cos, so that he and Theocritus must have been acquainted There are some curious parallels in the language and idioms of the two poets, but which of them copied the other it is impossible to determine

THEODOLITE, a surveying instrument consisting of two graduated circles placed at right angles to each other, for the measurement of horizontal and vertical angles, a telescope, which turns on axes mounted centrically to the circles, and an alidade for each circle, which carries two or more verniers. The whole is supported by a pedestal resting on footscrews, which are also employed to level the instrument.

Theodolites are designed to measure horizontal angles with greater accuracy than vertical, because it is on the former that the most important work of a survey depends; measures of vertical angles are liable to be much impaired by atmospheric refraction, more particularly on long lines, so that when heights have to be determined with much accuracy the theodolite must be discarded for a levelling instrument. When truly adjusted the theodolite measures the horizontal angle between any two objects, however much they may differ in altitude, as the pole star and any terrestrial object. The instrument is made in many forms and modern surveying has introduced a great degree of accuracy. For the uses of the theodolite and other details *see* SURVEYING The name has been a puzzle to etymologists. Various ingenious explanations have been given, all based on the apparent Greek form of the word, thus it has been derived from θεᾶσθαι, to see, ὁδός, way, and λιτός, smooth, plain; from θεῖν, to run, and δολιχός, long, and in other ways equally fanciful. Another imaginary origin has been suggested in a corruption of "the O deleted," *i e* , crossed out, the circle being crossed by diameters to show the degrees, others have found in it a corruption of "the alidade" (*q v.*) It would appear, however, to be taken from the O Fr. *theodolet* or *theodelet,* the name of a treatise by one Theodulus, probably a mathematician (see *Notes and Queries*, 3rd series, vii 337, 428, etc. Skeat, *Etym Dict.*, 1910).

THEODORA, the wife of the emperor Justinian (*q.v*), was born probably in Constantinople, though according to some in Cyprus, in the early years of the 6th century, and died in 547. According to Procopius, our chief but by no means a trustworthy authority for her life, she was the daughter of Acacius, a bear-feeder of the amphitheatre at Constantinople, and while still a child appeared on the stage Becoming a noted courtesan, she accompanied a certain Hecebolus to Pentapolis (in North Africa), of which he had been appointed governor, and, having quarrelled with him, betook herself first to Alexandria, and then back to Constantinople through the cities of Asia Minor In Constantinople she attracted the notice of Justinian. He desired to marry her, but could not overcome the opposition of his aunt, the empress Euphemia After her death (usually assigned to the year 523) the emperor yielded, and as a law forbade the marriage of senators with women who had followed the stage, this law was repealed Thereupon Justinian married Theodora They were some time after (527) admitted by Justin to a share in the sovereignty, and, on his death four months later, Justinian and Theodora became sole rulers of the Roman world. He was then about forty-four years of age, and she some twenty years younger Procopius relates in his unpublished history (Ἀνέκδοτα) many repulsive tales regarding Theodora's earlier life, but his evident hatred of her, though she had been more than ten years dead when the *Anecdota* were written, and the extravagances which the book contains, oblige us to regard him as a very doubtful witness. James Bryce discovered in Rome what is believed to be the only ms. of this so-called life of Justinian, he considered it worthless as an authority (*See* THEOPHILUS)

Theodora speedily acquired unbounded influence over her husband She had a right to interfere, for she was not merely his consort, but empress regnant. In the most terrible crisis of Justinian's reign, the great Nika insurrection of 532, her courage and firmness in refusing to fly when the rebels were attacking the palace saved her husband's crown, and no doubt strengthened her command over his mind. Officials took an oath of allegiance to her as well as to the emperor (*Nov.*, viii). Procopius describes her as acting with the greatest cruelties. The city was full of her spies, who reported to her everything said against herself or the administration. She surrounded herself with ceremonious pomp, and required all who approached to abase themselves in a manner new even to that half-Oriental court. She constituted herself the protectress of faithless wives against outraged husbands, yet professed great zeal for the moral reformation of the city, enforcing severely the laws against vice, and immuring in a "house of repentance" on the Asiatic side of the Bosphorus five hundred courtesans whom she had swept out of the streets of the capital. How much of all this is true we have no means of determining,

for it rests on the sole word of Procopius. But there are slight indications in other writers that she had a reputation for severity.

In the religious strife which distracted the empire Theodora took part with the Monophysites. As Justinian was a warm upholder of the decrees of Chalcedon, this difference of the royal pair excited much remark and indeed much suspicion, and if it is true that Theodora disapproved of Justinian's western conquests, her judgment must be acknowledged to have been correct. In other matters also the wife spoke and acted very differently from the husband; but their differences do not seem to have disturbed either his affection or his confidence.

Theodora bore to Justinian no son, but one daughter—at least it would seem that her grandson, who is twice mentioned, was the offspring of a legitimate daughter, whose name, however, is not given. According to Procopius, she had before her marriage become the mother of a son, who when grown up returned from Arabia, revealed himself to her, and forthwith disappeared for ever; but this is a story to be received with distrust. That her behaviour as a wife was irreproachable may be gathered from the fact that Procopius mentions only one scandal affecting it, and that with some hesitation, the case of Areobindus. Her health was delicate, and, though she took all possible care of it, frequently quitting the capital for the seclusion of her villas on the Asiatic shore, she died comparatively young. Theodora was small in stature and rather pale, but with a graceful figure, beautiful features, and a piercing glance There remains in the apse of the famous church of S Vitale at Ravenna a contemporaneous mosaic portrait of her, to which the artist, notwithstanding the stiffness of the material, has succeeded in giving some character.

Nearly all the evidence against Theodora is derived from the violently-written *Anecdota* of Procopius, and has therefore been suspected. (*See* esp Débidour's *L'Impératrice Théodora.*) Modern researches, particularly those of Panchenko, the Russian scholar, have vindicated the general credibility of Procopius Of course, he can frequently be convicted of unfairness; he always attributes the worst motives His description of the profligacy of Theodora only proves his familiarity with the pornography of Constantinople. But it rests on the solid witness of John of Ephesus that Theodora's youth was disreputable We gather too from other writers that she was harsh and tyrannical, as, for instance, from the references to her in the lives of the popes in the *Liber Pontificalis* (which used to pass under the name of Anastasius, the papal librarian). Her threat to the person whom she commanded to bring Vigilius to her was "nisi hoc feceris, per Viventem in saecula excoriari te faciam" Much of what we find in these lives is legendary, but they are some evidence of Theodora's reputation. Again, (3) the statute (*Cod*, v 4, 23) which repeals the older law so far as relates to *scenicae mulieres* is now generally attributed to Justin, and agrees with the statement of Procopius that an alteration of the law was made to legalize her marriage. There is therefore reason for holding that she was an actress. About the beauty, the intellectual gifts, and the imperious will of Theodora there can be no doubt She was evidently an extraordinary person, born to shine in any station of life.

Her fortunes have employed many pens. Among the later serious works dealing with them may be mentioned M. Antonin Débidour's *L'Impératrice Théodora: Étude Critique* (1885), which endeavours to vindicate her from the aspersions of Procopius; and among more imaginative writings are Sir Henry Pottinger's interesting romance *Blue and Green* (1879), M. Rhangabé's tragedy *Θεοδώρα* (Leipzig, 1884), and M. Sardou's play *Théodora,* produced in Paris in 1884. *See* also Dr. F. Dahn's *Prokopios von Cäsarea* (1865) and B. Panchenko in "Vizant Vremennik" vols. ii, iii and, in addition, the works cited under JUSTINIAN.

THEODORE, the name of two popes. Theodore I., pope from November 642 till May 649, succeeded John IV. He was the son of a bishop, and was born in Jerusalem. A zealous opponent of monothelitism, in the course of the protracted controversy he in a Roman synod excommunicated Pyrrhus, patriarch of Constantinople, and signed the document with ink mingled with consecrated wine. Theodore II. had a pontificate of only twenty days (Nov-Dec. 897).

THEODORE I. (1557-1598), tsar of Russia, the son of Ivan the Terrible and Anastasia Romanova, nominally succeeded his father in 1584, but being of weak intellect was governed throughout his reign by the boyar, Boris Godunov, whose sister Irene he married in 1580. On his death-bed he is said to have left the throne to his consort, with the Patriarch Job, Boris Godunov, and Theodore Romanov, afterwards the Patriarch Philaret, as her chief counsellors. Irene, however, retired into a monastery and her brother Boris stepped into her place

THEODORE II. (1589–1605), tsar of Russia, was the son of Tsar Boris Godunov and one of the daughters of Malyuta-Skuratov, the infamous favourite of Ivan the Terrible Passionately beloved by his father, he received the best available education for those days, and from childhood was initiated into all the *minutiae* of government, besides sitting regularly in the council and receiving the foreign envoys He seems to have been precociously intelligent, and the first map of Russia by a native, still preserved, is by his hand. On the sudden death of Boris he was proclaimed tsar (April 13, 1605). On July 10, he was murdered in his apartments in the Kreml

THEODORE III. (1661–1682), tsar of Russia, was the eldest surviving son of Tsar Alexius and Maria Miloslavskaya. In 1676 he succeeded his father. He had received an excellent education at the hands of Simeon Polotsky, the most learned Slavonic monk of the day, knew Polish, and even possessed the unusual accomplishment of Latin; but, disfigured and half paralyzed by disease, he had been an invalid from his birth. In 1679 he married his first cousin Agatha and assumed the sceptre His native energy was not crushed by his disabilities; and he soon proved as thorough a reformer as a man incompetent to lead armies and obliged to issue his orders from his litter, or his bed-chamber, could be His consort, Agatha, shared his progressive views On her death (July 4, 1681) Theodore married Martha Apraksina. He died on April 27, 1682, without issue.

THEODORE (602–690), seventh archbishop of Canterbury, was born at Tarsus in Cilicia in 602. On the death of Wighard, who had been sent to Pope Vitalian by Ecgberht of Kent and Oswio of Northumbria in 667, apparently for consecration as archbishop, Theodore, who had become prominent in the Eastern work of the church, was recommended by Hadrian of Niridanum to fill the vacant see. Vitalian consecrated Theodore in April 688 on condition that Hadrian, afterwards abbot of St. Peter's, Canterbury, should go with him Hadrian was detained for some time by Ebroin, the Neustrian mayor of the palace, but Theodore reached England in May 669. According to Bede's account he made a tour of the whole of Anglo-Saxon England, reforming abuses and giving instruction as to the monastic rule and the canonical Easter Bede also declares that he was the first archbishop to whom all the "church of the Angles" submitted

In 673 Theodore presided at the first synod of the clergy in England which was held at Hertford Various disciplinary regulations were emphasized, and an annual meeting arranged at a place called Cloveshoe After this council Theodore revived the East Saxon bishopric, to which he appointed Earconwald Soon after the first expulsion of Wilfrid in 678 he divided the Northumbrian diocese, appointing Trumwine bishop to the Picts This led to a quarrel with Wilfrid which was not finally settled until 686–687. In 679 Theodore intervened to make peace between Ecgfrith of Northumbria and Aethelred of Mercia. He presided at other synods held in 680 at Hatfield and in 684 at Twyford, and died in 690 A penitential composed under Theodore's direction is still extant.

See Bede, *Hist Eccl*, edited by C. Plummer (Oxford, 1896); Eddius, *Vita Wilfridi* in J Raine's *Historians of the Church of York*, vol i (London, 1879); *Anglo-Saxon Chronicle*, edited by Earle and Plummer (Oxford, 1899), Haddan and Stubbs, *Councils and Ecclesiastical Documents* (Oxford, 1869–78), iii. 173–213

THEODORE LASCARIS (d 1222), emperor of Nicaea, was born of a noble Byzantine family He became the son-in-law of the Emperor Alexius III. and distinguished himself during the sieges of Constantinople by the Latins (1203–04). After the capture of the city he gathered a band of fugitives in Bithynia and established himself in the town of Nicaea Relieved of the danger of invasion, owing to an incursion of Bulgarians into the Latin empire, he set to work to form a new Byzantine state in

Asia Minor, and in 1206 assumed the title of emperor. He defended himself stubbornly against the Latin emperor Henry, defeated his rival Alexius Comnenus of Trebizond, and carried out a successful counter-attack upon Gayath-ed-din, the sultan of Koniah. His crowning victory was gained in 1210, when in a battle near Pisidian Antioch he captured the deposed emperor Alexius III. and wrested the town itself from the Turks.

See A Meliarakes,'Ἱστορία τοῦ Βασιλείου τῆς Νικάιας καὶ τοῦ Δεσποτάτου τῆς 'Ηπείρου (Athens, 1898).

Theodore's grandson, Theodore II. (Lascaris), emperor from 1254 to 1258, is chiefly noticeable for two brilliant campaigns by which he recovered Thrace from the Bulgarians (1255–56). His ill-health and early death prevented his making full use of his ability as a ruler.

THEODORE OF MOPSUESTIA (*c.* 350–428/9), early Christian theologian, the most eminent representative of the so-called school of Antioch, was born at Antioch about the middle of the 4th century and was a friend of John Chrysostom; in rhetoric the celebrated Libanius was his teacher. Soon, however, he attached himself to the school of the great exegete and ascetic, Diodorus, a presbyter in Antioch, and with only a transitory period of vacillation, from which he was won back by Chrysostom, he remained faithful to the theology and ascetic discipline of this master Under Diodorus he became a skilful exegete, and ultimately outstripped his master in biblical learning. About 383 Theodore became a presbyter in Antioch, and began to write against Eunomius the Arian and against the christology of Apollinaris. Soon after 392 he became bishop of Mopsuestia in Cilicia (the modern Missis near Adana). As such he was held in great respect, and took part in several synods, with a reputation for orthodoxy that was never questioned. It was greatly to his advantage that in the Eastern Church the period between the years 390 and 428 was one of comparative repose. He was on friendly terms even with Cyril of Alexandria. He died in 428 or 429.

Theodore wrote commentaries on almost every book of the Old and New Testaments, of which, however, only a small proportion is now extant, as at a later period he lost credit in the church. We still possess in Greek his commentary on the Minor Prophets, in a Syriac version his commentary on St John[1], and, in Latin translations, commentaries on the shorter Pauline epistles, besides very many fragments, especially on the epistle to the Romans. Theodore's importance as an exegete lies in two characteristics. (1) in opposition to the allegorical method he insists on getting at the literal meaning, and adheres to it when found; (2) in his interpretation of the Scriptures he takes into account the historical circumstances in which they were produced, and substitutes the historical-typological for the pneumatico-christological interpretation of prophecy, in other words, he interprets all Old Testament passages historically in the first instance, and sees the fulfilment of Old Testament prophecy in the history of Christ and His church only in so far as the entire Old Testament is a "shadow of things to come."

Theodore also was the author of a special dissertation against the allegorists, *i e*, against Origen and his followers, which, however, has unfortunately perished. The comparative freedom of Theodore's view of inspiration is also noteworthy. He discriminates between historical, prophetical and didactic writings, and in accordance with this distinction assumes varying degrees of inspiration. Finally, he entertained very bold opinions about the canon and several of the books included in it He esteemed very lightly the Solomonic writings and the book of Job, Canticles he explained as a nuptial poem of Solomon's; the book of Job appeared to him in many places hardly worthy of its subject, and he censures the writer sharply; Chronicles, Ezra and Nehemiah he entirely rejected; he denied the accuracy of the titles of the Psalms, anticipated the hypothesis that many of them belong to the Maccabean age, and referred the so-called Messianic element almost invariably to the kings of Israel; he even criticized the Catholic epistles and rejected the epistle of James. Characteristics such as these bring Theodore, of all patristic writers, nearest to the modern spirit.

[1]Ed P. B Chabot (Paris, 1897)

Literature.—Migne, *Patrol.*, ser. Gr., lxvi. The Greek fragments of Theodore's New Testament commentaries have been collected by O. Fr. Fritzsche (*Theod. Mops. in N T. Comm.*, Turin, 1847). The commentaries on the Pauline epistles (Pitra, *Spicilegium Sotesmense*, Paris, 1852, i. 49 *seq*) have been edited by H. B. Swete (*Theod. Mops. in Epp. B. Pauli Comm.*, i, ii., Cambridge, 1880–82), along with the Greek fragments and the fragments of the dogmatical writings; on this edition, *see* E. Schürer, *Theol. Lit. Ztg.*, 1880–82. The commentary on the Minor Prophets will be found in Mai's *Nov. Patr. Biblioth.*, vii. 1854 (Berlin, 1834; Mai, *Script. Vet. Nov. Coll.*, vi., 1832). *See* also E. Sachau, *Theod. Mops. Fragm. Syriaca* (Leipzig, 1869); Fr. Bäthgen, "Der Psalmencommentar des Theod. v. Mops. in Syr. Bearbeitung," in *Ztschr. f. Alt-Test. Wissensch.*, v. 53 *seq.*, vi., 261–288, vii. 1–60; and H. Lietzmann in *Sitzungsberichte der Kgl preuss. Akad. der Wissensch, zu Berlin*, 1902, pp. 334 *seq.* Extracts from the writings of Theodore occur in the *Catenae* of Marius Mercator, in the *Acta* of the third and fifth oecumenical councils in Facundus, Liberatus, and Theodore's chief adversary Leontius Byzantinus E. von Dobschutz, in *Amer. Journ. of Theol.*, ii. 353–387, published the Greek prologue of a commentary on *Acts* that is probably the work of Theodore.

The principal monograph on Theodore, apart from the prolegomena of Swete, and the same writer's article in *Dict. Christian Biog*, iv. (1887), is that of H. Kihn (*Th. v. Mops. u. Junilius Afric. als Exegeten*, Freiburg, 1880). On his importance for the history of dogma *see* the works of Baur, Dorner, Harnack, Loofs and Seeberg Literary and biographical details will be found in O. Fr. Fritzsche, *De Theod. Mops Vita et Scriptis* (Halle, 1836), Fr A. Specht, *Theod. v. Mops u. Theodoret* (Munich, 1871), H. Kihn in the *Tub Quartalschr*, 1879; E Nestle in *Theol. Stud aus Wurtemb*, ii. 210 *seq*; P Batiffol, "Sur une Traduction Latine de Th. de Mops," in *Ann de Philos. Chrét*, 1885; Th. Zahn, "Das N T. Theodors von Mop.," in *Neue Kirchl Zeitschr*, xi. 788–806, W. Wright, *Syriac Literature* (London, 1894), R. Duval, *La littérature syriaque* (Paris, 1899). (A Ha.; X.)

THEODORET, bishop of Cyrrhus, an important writer in the domains of exegesis, dogmatic theology, church history and ascetic theology, was born in Antioch, Syria, about 386 At an early age he entered the cloister; and in 423 he became bishop of Cyrrhus, a small city in a wild district between Antioch and the Euphrates, where, except for a short period of exile, he spent the remainder of his life The date of his death is uncertain, but it must have been not earlier than 457

Commentaries.—As an exegete Theodoret belongs to the Antiochene school, of which Diodorus of Tarsus and Theodore of Mopsuestia were the heads He was not actually the personal disciple of either, but he adopted their methods, though without the consistency and boldness of the first-named His extant commentaries (those on Canticles, on the Prophets, on the book of Psalms and on the Pauline epistles) are brief.

Dogmatic Works.—Theodoret's chief importance is as a dogmatic theologian, as the most considerable opponent of the views of Cyril and Dioscurus of Alexandria For more than twenty years he maintained the struggle against the Alexandrian dogmatic and its formulae (θεοτόκος, ἕνωσις καθ' ὑπόστασιν, μία ὑπόστασις ἕνωσις φυσική, and the like), and taught that in the person of Christ we must strictly distinguish two natures (*hypostases*), which are united indeed in one person (*prosopon*), but are not amalgamated in essence For these years his history coincides with that of the Eastern Church from 430 to 451, and for this very reason it is impossible to sketch it even briefly here. (*See* Hefele, *Conc-gesch*, vol. ii.) The issue was not unfavourable to Theodoret's cause, but melancholy enough for Theodoret himself. the council of Chalcedon condemned monophysitism, but he unhappily yielded to pressure so far as also to take part in pronouncing "anathema upon Nestorius, and upon all who call not the Holy Virgin Mother of God, and who divide the one Son into two"

Some of Theodoret's dogmatic works are no longer extant: of his five books Περὶ ἐνανθρωπήσεως, for example, directed against Cyril after the council of Ephesus, we now possess fragments merely. A good deal of what passes under his name has been wrongly attributed to him. Certainly genuine are the refutation ('Ανατροπή) of Cyril's twelve ἀναθεματισμοί of Nestorius, and the 'Ερανίστης, or Πολύμορφος (written about 446), consisting of three dialogues, entitled respectively Ἄτρεπτος, 'Ασύγχυτος, and 'Απαθής, in which the monophysitism of Cyril is opposed, and its Apollinarian character insisted on. Among

the apologetico-dogmatic works of Theodoret must be reckoned his ten discourses Περὶ προνοίας.

Other Works.—The thirty ascetic biographies of his *Φιλόθεος ἱστορία,* which has been widely read, form a pendant to the *Historia Lausiaca* of Palladius and the monkish tales of Sozomen. For the East it has had the same importance as the similar writings of Jerome, Sulpicius Severus and Cassian for the West.

BIBLIOGRAPHY.—The edition of Sirmond (Paris, 1642) was afterwards completed by Garnier (1684), who has also written dissertations on the author's works. Schulze and Nosselt published a new edition (6 vols, Halle, 1769–74) based on that of their predecessors; a glossary was afterwards added by Bauer. The reprint will be found in vols. lxxx.–lxxxiv. of Migne, and considerable portions occur in Mansi. The church history has been published frequently in connection with the histories of Socrates, Sozomen and others, *e.g.*, by Valesius (1693) and Reading (1720). There is an English translation of the history by Bloomfield Jackson in the *Nicene and Post-Nicene Fathers,* series ii, vol. iii., the translation including also the dialogues and letters.

Besides the earlier labours of Tillemont, Ceillier Oudin, Du Pin and Fabricius and Harless, *see* Schrockh, *Kirchengesch*, vol. xviii; Hefele, *Conc-gesch*, vol ii, Richter, *De Theodoreto Epp Paul. Interprete* (Leipzig, 1822); Binder, *Études sur Théodoret* (Geneva, 1844); Staudlin, *Gesch u Lit der Kirchengesch.* (Hanover, 1827); Kihn, *Die Bedeutung der antioch Schule* (1866); Diestel, *Das A T. in der christl Kirche* (Jena, 1869); Specht, *Theodor v. Mopsvestia u. Theodoret v Cyrus* (Munich, 1871); Roos, *De Theodoreto Clementis et Eusebii Compilatore* (Halle, 1883), Nolte in the *Tubing Quartalschr* (1859), p 302 *seq*; Moller, art. "Theodoret," in Herzog-Hauck's *Realencykl*; Venables's article in Smith and Wace's *Dict. of Christian Biography;* also Bardenhewer's *Patrologie*, p 345 ff. (A. HA.; X.)

THEODORIC, king of the Ostrogoths (*c.* 454–526). Referring to the article GOTHS for a general statement of the position of this, the greatest ruler that the Gothic nation produced, we add here some details of a more personal kind Theodoric was born about the year 454, and was the son of Theudemir, one of three brothers who reigned over the East Goths, at that time settled in Pannonia The name of Theodoric's mother was Erelieva, and she is called the concubine of Theudemir. The Byzantine historians generally call him son of Walamir, apparently because the latter was the best known member of the royal fraternity. At the age of seven he was sent as a hostage to the court of Constantinople, and there spent ten years of his life. Soon after his return to his father he secretly attacked the king of the Sarmatians, and wrested from him the important city of Singidunum (Belgrade) Theodoric took the chief part in an expedition into Moesia and Macedonia, the result of which was to settle the Ostrogoths as *foederati* in the heart of the empire About 474 Theudemir died, and for the fourteen following years Theodoric was chiefly engaged in a series of profitless wars, partly against the emperor Zeno, but partly against a rival Gothic chieftain, another Theodoric, son of Triarius In 488 he set out, with the sanction of the emperor, to win Italy from Odoacer. The invasion and conquest of Italy occupied more than four years (488–493) Theodoric, who marched round the head of the Venetian Gulf, had to fight a fierce battle with the Gepidae, probably in the valley of the Save. At the Sontius (Isonzo) he found his passage barred by Odoacer, over whom he gained a complete victory (28th of August 489). A yet more decisive victory followed on the 30th September at Verona Odoacer fled to Ravenna, and it seemed as if the conquest of Italy was complete. At length (26th of February 493) the long and severe blockade of Ravenna was ended by a capitulation, the terms of which Theodoric disgracefully violated by slaying Odoacer with his own hand (15th of March 493). (*See* ODOACER.)

The thirty-three years' reign of Theodoric was a time of unexampled happiness for Italy. Unbroken peace reigned within her borders (with the exception of a trifling raid made by Byzantine corsairs in 508). The venality of the Roman officials and the turbulence of the Gothic nobles were sternly repressed Marshes were drained, harbours formed, the burden of the taxes lightened, and the state of agriculture so much improved that Italy, from a corn-importing, became a corn-exporting country. Moreover Theodoric, though adhering to the Arian creed of his forefathers, was during the greater part of his reign conspicuously impartial in religious matters. At the time of the contested papal election between Symmachus and Laurentius (496–502), Theodoric's mediation was welcomed by both contending parties. Unfortunately, at the very close of his reign (524), the emperor Justin's persecution of the Arians led him into a policy of reprisals. He forced Pope John to undertake a mission to Constantinople to plead for toleration, and on his return threw him into prison, where he died. Above all, he sullied his fame by the execution of Boetius and Symmachus. (*See* BOETIUS). Theodoric's death, which is said to have been hastened by remorse for the execution of Symmachus, occurred on the 30th of August 526. He was buried in the mausoleum which is still one of the marvels of Ravenna (*q v.*), and his grandson Athalaric, a boy of ten years, succeeded him, under the regency of his mother Amalasuntha

AUTHORITIES—The most important source for Theodoric's life reign (ed in *Monumenta Germaniae Historica,* vol. xii.) is the *Variae* (state-papers) of Cassiodorus, chief minister of Theodoric The most modern work is Hartmann's *Geschichte Italiens im Mittelalter,* vol i. (Stuttgart, 1923) The English reader may consult Gibbon's *Decline and Fall,* chap. xxxix., and Hodgkin's *Italy and her Invaders,* vol iii. (1885), his introduction to *Letters of Cassiodorus* (1886) and *Theodoric the Goth* (London and New York, 1891).

THEODORUS STUDĪTA [Theodore of the Studion] (A D. 759–826), abbot of the monastery of the Studion, Constantinople, succeeded his uncle Plato, as head of the monastery of Saccudium in Bithynia in 794. He was banished to Thessalonica in connection with the marriage of Constantine VI After the emperor's death in 797 he was recalled and removed with his monks to the monastery of the Studion in Constantinople, where he carried on a vigorous campaign in favour of asceticism and monastic reform In 809 he was again banished in consequence of his refusal to hold communion with the patriarch Nicephorus, who had pardoned the priest Joseph for his part in the marriage of Constantine and Theodotē. In 811 he was recalled by Michael Rhangabes, and again banished in 814 for his opposition to Leo the Iconoclast. He was liberated in 821 by the Emperor Michael the Stammerer (Balbus). In 824 he violently attacked Michael for iconoclasm and was forced to leave Constantinople He lived at various monasteries until his death on Nov. 11, 826 He was buried at Chalcitis, but his body was afterwards (Jan 26, 844) removed to the Studion He subsequently received the honours of canonization. Of his extant works the following are the most important.—The three λόγοι ἀντιρρητικοί and other works in defence of images and his *Letters* He was also the composer of hymns, many of which are still extant Like all the monks of the Studion, Theodore was famous for his calligraphy and industry in copying mss

Pitra, *Analecta Sacra,* i (1876) *See* also Alice Gardner, *Theodore of Studium: his Life and Times* (1905) For further bibliographical details *see* C Krumbacher, *Gesch der byz Lit* (2nd ed, 1897) and article by Von Dobschutz in Herzog-Hauck's *Realencyclopädie für protestantische Theologie,* xix. (1907).

THEODOSIA, formerly Kaffa, a seaport and watering-place of South Russia, on the east coast of the Crimea, in 45° 3′ N., 35° 22′ E, and on the railway. It has an excellent modern harbour, which is never frozen and has a floating crane lifting 40 to 50 tons Pop (1926) 27,347.

The ancient Theodosia, the native name of which was Ardabda, was a colony founded from Miletus. Archaic terra-cottas show it to have been inhabited in the 6th century B C., but it is first heard of in history as resisting the attacks of Satyrus, ruler of the Cimmerian Bosporus, *c* 390 B C His successor Leucon took it and made it a great port for shipping wheat to Greece, especially to Athens. This export of wheat continued until the days of Mithradates VI of Pontus, against whom the city revolted Later it became a special part of the Bosporan kingdom with its own governor. In the 3rd century A D. it was still inhabited, but seems to have been deserted not long afterwards. Besides the terra-cottas and pottery, very beautiful Greek jewellery has been found near Theodosia. It coined silver and copper during the 5th and 4th centuries B C. The name Kaffa (Genoese *Capha*, Turk *Kefe*) is first mentioned in the 9th century. The Genoese established themselves on the site shortly after 1266, and the settlement flourished exceedingly, being the depôt of a trade route reaching

to China. It became the head of the Genoese establishments in Gazaria, the see of a bishop, and the chief port on the northern shore of the Black sea, surpassing the Venetian Tana When the Turks took Constantinople the colony was almost cut off from the mother city, which handed it over to the enterprising bank of St. George; but it could not be saved and fell in 1475 to the Turks, who sometimes called it Kuchuk-Stambul (Little Stambul) or Constantinople, or Krym-Stambul (Stambul of Crimea). In 1771 it was taken by the Russians, and in 1783 annexed by them, whereupon the greater part of its population deserted it.

See E. von Stern, *Theodosia* (German and Russian, 1906); E. H. Minns, *Scythians and Greeks* (1909); M Rostovtzeff, *Iranians and Greeks in South Russia* (1922), for the history of Kaffa, *see* Heyd, *Histoire du commerce du Levant au moyen âge* (1886).

THEODOSIUS, the name of three Roman emperors of the East.

THEODOSIUS I, "the Great," son of Theodosius, Valentinian's great general, who in 368–69 saved Britain from the Picts, and suppressed the revolt of Firmus in Mauretania (372) Shortly after (376), the elder Theodosius was put to death, perhaps by order of Valens. The younger Theodosius was born about the year 346. He was a native of Spain, but the exact place of his birth is uncertain. He accompanied his father into Britain (368), and a little later defeated the Sarmatians who had invaded Moesia (374). On his father's death he retired to his native place, where he lived quietly till after the great battle of Adrianople (Aug. 9, 378), when Gratian summoned him to share the empire. After gaining some fresh victories over the Sarmatians, Theodosius was made Augustus at Sirmium on Jan 19, 379, and was assigned all the eastern provinces, including part of Illyricum. In 379 Theodosius, after reorganizing the army at Thessalonica, carried on a successful campaign of skirmishes along the Danube and induced numerous Gothic bands to give in their allegiance, his lieutenant Modares, a Gothic refugee, defeated the invaders severely in Thrace. In 381 he was called upon to meet two armies of invaders. He conducted in person the war against the Visigoths under Fritigern, this campaign, being only ended by Fritigern's death. The defence of the Danube against the Ostrogoths under Alatheus and Safrax was entrusted to the general Promotus, who severely defeated the enemy in an attempt to cross the river. Theodosius attained even greater successes by his diplomacy. He persuaded the fugitive Visigoth king Athanaric to enter his service, and enlisted 40,000 of his former enemies as *foederati,* providing them with settlements in various parts of the realm

In 383 Theodosius created his eldest son Arcadius Augustus. The same year saw the revolt of Maximus in Britain and the murder of Gratian. For five years Theodosius consented to accept the usurper as his colleague; but when Maximus attempted a few years later to make himself master of Italy Theodosius advanced against the invader and overthrew him near Aquileia (July 28, 388). This victory was followed by the murder of Maximus and his son Victor, after whose death Theodosius conferred upon Valentinian II all that part of the empire which his father had held. After celebrating a triumph in Rome (389) he stayed to arrange the government of Italy for another two years. If we may trust the evidence of Zosimus, from the end of the year 388 Theodosius resigned himself to gluttony and voluptuous living, from which he was only roused by the news that in the Western empire Arbogast had slain the young Emperor Valentinian and set up the grammarian Eugenius in his stead (May 15, 392).

Theodosius at once marched out against Eugenius. The armies met near the river Frigidus, some thirty-six miles distant from Aquileia On the first day Theodosius' barbarians, engaging with those of the hostile army, were almost destroyed, and the victory seemed to be with Eugenius After a night of prayer, towards cockcrow the emperor was cheered by a vision of St. Philip and St. John, who, mounted on white steeds, promised him success. On the second day the issue was doubtful till, if we may trust the concurrent testimony of all the contemporary church historians, a sudden gust of wind blew back the enemy's arrows on themselves. This was the turning-point of the battle: Eugenius was slain by the soldiers; and two days later Arbogast committed suicide (Sept. 5–9, 394). From the north-eastern parts of Italy Theodosius passed to Rome, where he had his son Honorius proclaimed emperor under the guardianship of Stilicho. Thence he retired to Milan, where he died of dropsy (Jan. 17, 395), leaving the empire to be divided between his two sons Honorius and Arcadius

The chief authorities for the age of Theodosius are Ammianus Marcellinus, Zosimus, Eunapius and the ecclesiastical historians (Socrates, Sozomen, Theodoret). Much information may also be gleaned from the writings of St Ambrose, St. Gregory of Nazianzus, Isidore of Seville, and the orators Pacatus, Libanius, Themistius. Among modern authorities see: E Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, 1909), chaps. 25 and 27; T. Hodgkin, *Italy and her Invaders* (Oxford, 1892), chaps. 5, 6, 8–11; A. Güldenpenning and J. Ifland, *Der Kaiser Theodosius der Grosse* (Halle, 1878); G. R. Sievers, *Studien zur Geschichte der romischen Kaiser* (Berlin, 1870), pp. 283–333, and Van Ortroy, *St. Ambroise et l'Empereur Théoduse,* Analecta Bollandiana (1904).

THEODOSIUS II. (401–450) succeeded his father Arcadius as emperor of the East in 408 During his minority the empire was ably ruled by the praetorian prefect Anthemius and Pulcheria, who became her brother's guardian in 414. Under his sister's care the young emperor grew up into a weak though amiable character. Through his generals Ardoburius and Aspar he waged two fairly successful wars against the Persians (421 and 441), and after the failure of one expedition (431) by means of a gigantic fleet put an end to the piracies of the Vandal Genseric. A Hunnish invasion in 408 was skilfully repelled, but from 441 the Balkan country was repeatedly overrun by the armies of Attila, whose incursions Theodosius feebly attempted to buy off with ever-increasing payments of tribute. His internal administration was upright and thoughtful. Among its chief events may be mentioned the council of Ephesus (434) and the publication of the *Codex Theodosianus* (438), a collection of imperial constitutions for the benefit of public officials Theodosius died in 450.

See E. Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, London, 1909) 406–414; 440–470, J B Bury, *Later Roman Empire,* vol. i (1923), A Güldenpenning, *Geschichte des ostromischen Reiches unter den Kaisern Arkadius und Theodosius II* (Halle, 1885), pp. 172 *sqq.;* T. Mommsen and P. Meyer, *Theodosii libri XVI* (Berlin, 1904–05; in course of revision by E Kiegel, 1926).

THEODOSIUS III., emperor of the East (716–717), was a financial officer whom a Byzantine army rebelling against Anastasius III unexpectedly proclaimed monarch in his stead He captured Constantinople after a six months' siege and deposed Anastasius, but in the following year was himself forced to resign by a new usurper, Leo III (*q v*) Theodosius ended his life in a monastery.

See G Finlay, *History of Greece* (ed. 1877, Oxford), i p. 396).

THEODOSIUS, Greek geometer and astronomer, was the author of three works included in the collection of treatises known as the "Little Astronomy" or "Astronomer" (ὁ μικρὸς ἀστρονούμενος or ἀστρονόμος). He was not "of Tripolis," but came from Bithynia, as we gather from Strabo, who mentions, among natives of Bithynia famous for their learning, "Hipparchus, Theodosius and his sons, mathematicians"; he is also evidently the Theodosius mentioned by Vitruvius as the inventor of a universal sun-dial (*horologium* πρὸς πᾶν κλίμα). He lived, therefore, not later than the 1st century B.C.

His chief work, the *Sphaerica,* in three books, is a tolerably complete treatise on the pure geometry of the sphere, and was still the classical book on the subject in Pappus's time. It does not contain (except for a faint suggestion in iii. 11–12) any trace of spherical trigonometry, which, on the other hand, was the special subject of the work with the same title by Menelaus of Alexandria, who lived at the end of the 1st century.

From the fact that both Autolycus of Pitane in his *Moving Sphere* and Euclid in his *Phaenomena* assume without proof various propositions given by Theodosius, we conclude that already in the 4th century B.C. there existed a textbook on *Sphaerica* scarcely differing, in its essential contents, from Theodosius's work; the rôle of Theodosius was therefore mainly that of editor and elaborator of previously existing material The *Sphaerica* was translated into Arabic in the 9th century, in part by Qusṭa b. Lūqā, and

in part by Thâbit b. Qurra. Latin translations were made from the Arabic in the 12th century by Plato of Tivoli (Tiburtinus) and Gherard of Cremona, and various editions in Latin appeared from 1518 onwards, including one by Barrow (*Theodosii Sphaerica, Methodo Novo Illustrata et Succincte demonstrata*, London, 1675). We now have a definitive Greek text (with Latin translation) by J. L. Heiberg (Berlin, 1927).

The two other works of Theodosius which have come down to us were first published in a Latin translation by Joseph Auria, *On Days and Nights*, in two books (with scholia, etc.) in 1591, and the tract *On Habitations* (Περὶ οἰκησέων) in 1587 (Rome); a critical edition of the Greek text of both (with Latin translation) by Rudolf Fecht appeared in Berlin in 1927. (T. L. H.)

THEODULF, bishop of Orleans, was born about the middle of the 8th century, of a noble family of Gothic extraction, probably in Spain. He was made abbot of Fleury and of Saint-Aignan, and in 781 became bishop of Orleans. He supported Charlemagne's principles of government and educational reforms; he established schools, and was a member of the learned circle which graced the Carolingian court. In 798 he was appointed *missus dominicus*, and two years later performed so great services for Leo III as judge in the cause between the pope and his enemies, that he returned from Rome with the pallium. After the death of Alcuin he became the king's principal theological adviser, it was he who made, on Charlemagne's request, a collection of the opinions of the fathers on the much-disputed point of the procession of the Holy Ghost. After the death of Charlemagne, he was accused, probably quite unjustly, of having taken part in the conspiracy of Bernard of Italy, and in 818 was deposed and imprisoned in a monastery at Angers. He died in prison, probably from poison, in 821.

The complete works of Theodulf are in J. P. Migne, *Patrol. Lat.*, vol. 105 (Paris, 1851). The best edition of his poetry is that of E. Dümmler in the *Mon. Germ. Hist. Poetae latini aevi carolini*, vol. i. (Berlin, 1881).

See C. Cuissard, *Théodulphe évêque d'Orléans, sa vie et ses oeuvres*, (Orleans, 1892), and a critical study of the writings by M. Manitius in *Neues Archiv der Ges. fur a. deutsche Gesch.* xi. (1886).

THEOGNIS OF MEGARA (6th century B.C.), Greek poet. More than half the elegiac poetry of Greece before the Alexandrian period is included in the 1,400 lines ascribed to Theognis. This collection contains several poems acknowledged to have been composed by Tyrtaeus, Mimnermus and Solon; with two exceptions (T. W. Allen in *Classical Review*, Nov. 1905, and E. Harrison) modern critics unanimously regard these elegies as intruders, that is, not admitted into his works by Theognis himself; for this and other reasons they assume the existence of further interpolations which we can no longer detect.

The best-attested elegies are those addressed to Cyrnus, the young friend to whom Theognis imparts instruction in the ways of life, bidding him be true to the "good" cause, eschew the company of "evil" men (democrats), be loyal to his comrades, and wreak cruel vengeance on his foes. Theognis lived at Megara on the Isthmus of Corinth during the democratic revolution in the 6th century B.C.; some critics hold that he witnessed the "Persian terror" of 590 and 580; others, including the present writer, place his *floruit* in 545 B.C.

There is neither profound thought nor sublime poetry in the work of Theognis; but it is full of sound common-sense embodied in exquisitely simple, concise and well-balanced verse. In his day verse was the recognized vehicle for political and ethical discussion, and the gnomic poets were in many ways the precursors of the philosophers and the sophists, who indeed often made their discourse turn on points raised by Theognis and his fellow-moralists. For many generations Theognis was to the Greeks the moralist *par excellence;* Isocrates says that Hesiod, Theognis and Phocylides were admitted to be the best teachers of practical morality; and the Emperor Julian in his defence of paganism asks whether "the most wise Solomon is equal to Phocylides or Theognis or Isocrates."

Besides the elegies to Cyrnus the Theognidea comprise much miscellaneous verse that may well have come from Theognis.

Editions by Imm. Bekker (1815, 2nd ed. 1827); F. G. Welcker (1826); both these are epoch-making books which no serious student can ignore; Th. Bergk (1843, 4th ed. 1882, re-edited by E. Hiller, 1890, and O. Crusius, 1897), J. Sitzler (1880); E. Harrison, *Studies in Theognis*, with text (1902); T. Hudson-Williams (1910). For further bibliographical references *see* the two last-mentioned books. There is a prose translation by J. Banks in Bohn's Classical Library (1856), which also includes verse translations by J. Hookham Frere.

(T. H. W.; X.)

THEOLOGICAL ARTICLES: *see* RELIGION, ARTICLES ON.

THEOLOGY, in the comprehensive sense of the name, embraces so much of philosophy as is concerned with explanation of the world in terms of a supreme mind or spirit, with the being and attributes of the Deity and His relation to Nature and man and with the grounds and the limits of knowledge or belief as to such matters. It also includes the comparative study of religions and the psychology of religious experience. Specifically Christian theology, which is often what is denoted by the word "theology," sets forth the contents and implications of the revelation in Christ. It consists of a systematic exposition of doctrine and of the course of its development (*dogmatic theology* or *dogmatics*), the historical, critical and exegetical study of the Bible, and the history of the Church, its institutions, etc. Thus theology is a science, or a group of connected sciences, that, on the one hand, is in touch with general philosophy—as is indicated by the name of the department called "philosophy of religion," or "philosophical theology"—and, on the other hand, is more or less isolable in that it deals with the deliverances of distinctively religious experience and its pre-eminent manifestations.

The Relation of Theology to Religious Experience.—It is commonly held that religious experience contains data other than those of natural knowledge, enabling it to possess insight into reality otherwise unattainable. And we may first note the implications of this belief in their bearing on the position of theology amongst other departments of thought such as natural science and philosophy. All natural knowledge, *i.e.*, knowledge of the physical world and mankind, is now generally believed by philosophers to be derived originally from the impressions of sense, between which the understanding establishes relations. Out of these relations are constructed the body of common-sense knowledge, the sciences and metaphysics. Sensory perception in the first instance, and then ideas distilled from percepts, evoke the feelings, desires and valuations, of which aesthetic and ethical sentiments and principles are the outcome. According to this science or theory of knowledge, then, religious beliefs and theological doctrines can only be mediated by reflection on the sensible world, the mind of man and human history. On the other hand it is often claimed by theologians that religious experience is founded on apprehension of another species of the objective than the sensory or the sense-derived, and on feelings, etc., induced thereby. This objective datum, evocative of unique emotional states and dispositions, is asserted to be apprehended with the same immediateness as is the sensory and so to afford a basis of knowledge about ultimate reality, independent of that on which the natural sciences are built.

If this view were beyond criticism, it would suffice to explain the uniqueness of religious experience and consequently the special characteristics of theology. And one ingredient in it certainly seems to be beyond reasonable doubt. This is that whatever there is, on the affective or emotional side of religious experience, that renders it an experience *sui generis*, or distinct from cognate kinds of experience, that peculiarity must be accounted for by the distinctiveness of the object or objects eliciting the subjective response. Religious experience, on its affective side, comprises sentiments such as loyalty and love, awe and adoration, none of which is peculiar to religion, but each of which differs somewhat from other instances of love, reverence, etc., solely in virtue of the object—deity—towards which the religious emotion is a response. Even those who incline to the opinion that there is one kind of valuation, viz., appreciation of sacredness, that is peculiar to religion throughout all the stages of its development, ascribe its peculiarity and its forthcomingness to the unique object that evokes it. But doubtfulness attaches to the

further representations that this sacred, numinous or supernatural object is immediately apprehended as such; that it is irreducibly different in psychological nature from the sensory, or rather from the image or the idea which are derived from the sensory, and that its apprehension involves a special faculty, not included among those known to ordinary psychology In the primitive stages of religion the supernatural object seems always to be lodged in some natural object or phenomenon, which inspired emotion such as awe, as is evinced in the notions of clean and unclean, worship of animals, the dead, etc. Thus the numinous, or divine, reality, devoid of the concrete particularity that characterizes an immediate sensation or percept, and capable of entering into diverse mythologies and religions, seems rather to be of the nature of the vague generic image, derived by human imagination and idealization from impressive phenomena And it is not enough to point to the indubitable objectivity (in the psychological sense) of this alleged numinous reality. For images and ideas, as well as percepts, are also objective; and they are as potent as actualities or real things in eliciting valuation and emotional response, provided that belief in their reality is entertained. Immediacy is a conception which plays important parts in connection with religion and theology; and attention may here be called to the ambiguity which lurks in it and is wont to be overlooked At the moment when a particular experience, such as perceiving a familiar thing, takes place, we are not aware of performing any synthetic activities; the percept has the unity and the instantaneousness of a flash-photograph, and the whole act of perceiving seems as if unanalysable and unconditioned by previous experiences. From the standpoint of such an experience, the perception is immediate. But from the standpoint of subsequent reflection on that experience, especially if we happen to be versed in the science of psychology, the perception in question was not immediate It was not a simple, unanalysable, unity nor unconditioned by previous mental processes and present interpretation. Its immediacy thus resolves into our unawareness, at the moment, of real mediation. Now in order to maintain that religious experience, as illustrated by the primitive instance that has been mentioned consists in immediate apprehension of a spiritual environment or a supernatural beyond, that is real or actual and not imaginal or ideal, it is essential that the immediacy involved be accounted such from the latter of the two points of view that have just been distinguished Yet it is from the former of them alone that it can be vouched for by the religious experient, appealing only to his religious experience. Thus it is doubtful, on more than one ground, whether apprehension of the sacred and supernatural is essentially different from sensory knowledge, eked out with interpretative notions derived from human analogy, constructive imagination and idealization. It may be that the primitive notion of a god, precursor of the later conception of God, was derived by such processes from current knowledge of man, and read into some impressive natural object, constituting it numinous and capable of eliciting religious emotion

If this view be adopted, religious experience, on its first emergence in mankind, will, *mutatatis mutandis,* have been grounded in a way similar to that in which theistic belief is grounded by the philosopher. It was the outcome of what may be called primitive philosophizing on Nature and man, and not of the exercise of an alleged transcendent faculty of intuition. Indeed it would seem that such direct touch of God upon the human soul as religion and theology imply does not admit of being discerned with real immediacy. it is a case of causal activity, which admittedly is never perceptible. And as for the rest that has been said above, its gist is contained in the generally endorsed dictum, "no man hath seen God at any time." The mystic, it is true, claims to be an exception. But it is not necessary here to weigh his testimony, partly because he can only assert, on the strength of his peculiar experiences, the specious kind of immediacy which has already been shown to be irrelevant, and partly because mystical experience seems never to have issued in theological insight and doctrine that was unknown before and otherwise. Knowledge of God would seem to be in the same case with knowledge of our own souls and of other selves, as distinct from their material bodies. In each of these instances the object is not apprehended with directness, but read in analogically; and the reading or interpretation is justified or verified (never logically certified) by cumulative practical success. There well may have been, from the infancy of our race, a touching of man by God, even before man arrived at belief in the daemonic or the divine; but such *rapport* would not be religion until man had come to believe in such beings as gods. "He who cometh to God must believe that He is." That is to say, religion or religious experience presupposes, and is constituted distinctive, by a theological notion or concept. This concept cannot be in the first instance derived from religious experience, because religious experience cannot exist till the idea is forthcoming

It is very generally taught that theology presupposes religious experience and is but the explication of it. But it is all a matter of where, in a long chain of development, we fix our starting point for consideration. In the series of natural numbers, every odd number precedes an even number and every odd number also succeeds an even number until we work back to 1. Similarly, the "Athanasian" creed presupposes much Christian experience while the religious experience of Paul the Apostle differed from that of Paul the Rabbi in virtue of his acquired doctrinal belief as to the Person of Christ But if we go back to the beginning of the series in which theology determines religious experience and in turn is determined by such experience, pursuing psychological beginnings since historical origins are beyond our ken, it would seem that, originally, some crude equivalent to natural theology must have preceded and caused the emergence of distinctively religious experience. But religious experience once having arisen in this way, it will determine theological thought; and the new thought will render possible a further advance in religious experience, and so on Thus there is as much truth in the statement that theological doctrine determines the quality of religious experience as in the statement that religious experience and faith are presupposed by theological dogmas. When, *e g*, the Christian asserts that he has experience of the indwelling Christ, he is obviously interpreting his really immediate experiences, which consist in consolations, joy, peace, uplifting of the will, etc He would not so interpret such mental happenings had not Christ been preached to him, and had he not received doctrine as to the Person of Christ which he did not make out of his individual experience. Nevertheless, it is a fact that the idea of God, both in dogmatic theology and in philosophy, was moulded by religious experience, guided both by morality and intellect, after the initial stage of the long course of religious development.

The Relation of Theology to Philosophy.—From the earliest times philosophy has had a theological side Since the dawn of Greek science and metaphysic, philosophy, Greek and other than Greek, has produced copious speculation concerning the existence and nature of God, as well as a vast volume of thought bearing more or less direct relevance to theological problems, such as the origin, destiny and meaning of the world and human life The greatest of philosophers have dealt with these problems and it has often been from the side of religion that great thinkers have received their chief impulse towards philosophy. Moreover theology and philosophy are largely identical in that theology is essentially metaphysics. No doubt the majority of those who profess theological beliefs hold their beliefs in complete absence of metaphysical reasoning; in that sense their belief—*i.e.*, believing—is non-metaphysical. But their beliefs—*i.e.*, their *credenda*—are all metaphysical dogmas or assertions about ultimate reality. They are religious beliefs in so far as they are metaphysical. For instance, that Jesus "suffered under Pontius Pilate" is, as a bare historical fact, of no religious import; but when it is intended to imply further that He suffered for us—*i.e.*, for our salvation—it is a metaphysical statement concerning the relation of God to human souls and, in virtue of that metaphysical content, is a religious doctrine.

Besides being concerned with the same metaphysical subject-matter, philosophy is involved in theology and can aid its work in various ways. Firstly, in respect of the systematization and unification of knowledge. Christian theology needs must connect

its more or less separate and independently elaborated doctrines into a coherent whole. Thus Origen, one of the first Fathers to present an ordered system of Christian dogma, tells us that while the Apostles delivered themselves clearly on certain points necessary for all to understand, they left the grounds of their utterances and the more precise determination and demonstration of many doctrines to the more zealous of their successors who should be "lovers of wisdom"; and he expresses his desire to form a connected series of truths or one body of doctrine. That is the goal of dogmatic theology which would relate, *e g*, the doctrine of the Atonement with that of the Incarnation or the doctrine of Sin with that of Creation, and obviously such connection involves resort to philosophy Again, the exposition of any single doctrine involves the use of interpretative ideas, such as can only be supplied by the science and philosophy current in a given age Several doctrines that purport to be deduced from scripture alone are less the result of strict exegesis than the result of speculation applied to such material as secular knowledge was believed to have established. To give one example: the doctrine of Original Sin is not contained in the Old Testament and the only unmistakable presentation of it that can be found in the New does not appear to have been the starting-point for the first framers of the ecclesiastical doctrine Tertullian set out from stoic psychology, Origen from the institution of infant-baptism and also from the myth of Plato concerning the fall of the soul from the celestial sphere into earthly life. But of greater importance than cases of this kind is the fact that the very terms and conceptions, requisite as a mould into which the relatively undefined traditional beliefs of the early Church must be cast in order to yield explicit and definite doctrine and, appropriated for that purpose, were supplied by Greek philosophy

The office of philosophy within the sphere of theology, with which we have thus far been concerned, may be described as that of interpreting to the reason the contents of religious experience. The philosophy of religion seeks to show that the fundamental ideas of religion, so far from being contrary to reason or from being ideas begotten of faith indifferent to knowledge, are capable of receiving a rational, or at least a reasonable, justification in terms of philosophical principles. Philosophy, or even theology, is no substitute for religion, and, of course, does not profess to be It professes, rather, to show the compatibility of faith with reason and knowledge and to interpret the contents of faith to the reason.

Another function of philosophy is the undertaking of a critical examination of the processes involved in what we call knowing and of the various conceptions that enter into the knowledge claimed either by common sense or the sciences, with a view to disclosing the nature, validity and limits of human knowledge. And this function has a necessary place also in the sphere of theology. There we require to understand the precise relations between what are respectively called knowledge and faith; and it is necessary to pursue the "critical regress" within the field of dogmatic theology because, as history shows, the legitimate desire for completeness of system and knowledge and for definiteness of dogmatic expression is apt to become the wish to know more than, perhaps, can be known and to know too definitely. In the middle ages, when theology was more ambitious than critical, fulness and precision were claimed in so inordinate a degree that, as a sympathetic historian has observed, an agnostic reaction was necessary in the interests of reverence. And it is always natural for theologians to betake themselves too exclusively to the drawing of inferences when more attention might profitably be devoted to the sifting of premisses. Thus it is that the word "dogmatic," which technically indicates one province of theology, has come sometimes to bear a less noble signification; and dogmatic theology has been distrusted as requiring assent to doctrines that are not self-evident and for which no proof can be supplied.

But while philosophy, as a critical method, is a corrective of dogmatism in the foregoing sense, philosophical theology is not necessarily hostile to dogma. Individual philosophers have doubtless tended to set up empty abstractions, as will presently be seen, in place of positive facts and concrete existents; but that is no necessity inherent in philosophy itself, as a pursuit.

Hegel observes in his *Philosophy of Religion* that in his day an anti-dogmatic spirit was abroad among dogmatic theologians, who at the same time charged philosophy with merely negative or destructive tendencies These, he said, have thrust dogmas into the background, pronouncing them unimportant and extraneous definitions or mere phenomena of past history. Christ's work of redemption had received a very prosaic and merely psychological significance and the doctrines of the Trinity, etc., were neglected as matters of indifference, even by pious theologians This spirit was by no means confined to Hegel's day. It might be called the temper of indefiniteness. It is met with in the supposed antitheses between kernel and husk—as if kernels ever grew without husks—and between the life and the creed—as if Christianity were not a life based on a creed, and Christian ethic did not owe its distinctiveness to its dependence on Christian doctrines In recoiling from dogmatism such as would be over-precise, it distrusts precision of expression as such.

The necessary and intimate connection of theology, even dogmatic theology, with philosophy now having been illustrated from several sides, the two main types of method that have been employed in philosophical theology may in turn be described: they are respectively called the *a priori* and the empirical

The a priori Method and Rational Theology.—Of the phrase *a priori* we can distinguish two meanings that are apt to be confounded It may have a psychological sense, when the phrase means "contributed by the mind itself," and so is generally equivalent to "innate" It may also bear a logical sense, as when *a priori* truth is described as truth characterized by universality such as, in contrast with mere generality, bespeaks intrinsic or unmediated necessity In the former case, contrast with the empirical and sense-given is pointed, in the latter case, contrast with the contingent—*i.e*, with what is, but conceivably might have been otherwise

It may be said, with accuracy sufficient for the present purpose, that the *a priori* method was introduced into philosophy and theology by Plato He took the ideal or pure science of mathematics, which deals with the non-actual, to be the paradigm of knowledge of the actual—science and philosophy Despising the sensory, and empirical investigation, he valued only the relations and the universal qualities manifested in facts, so that these came to be considered, not as entering into the constitution of actuality, but as existing wholly independently, and this rational or intelligible world, as contrasted with the sensorily perceived, was accounted the truly existent or the "real" Thus arose the *a priori* method, in the logical sense of that phrase, and the rationalistic theory of knowledge, which, without much qualification, may be said to have dominated philosophy for centuries So long as it did not and could not—till analytical psychology was born—be suspected that sense and understanding may have a common root and that between understanding and reason there is continuity rather than disparateness, the rationalist's belief in a faculty called reason, capable of functioning in independence of sensation and sensory data, was possible and natural. This faculty was regarded by the ancient philosophers as the sole source of real, *i.e*, higher, knowledge; as independent of body and "animal soul," and even as a participation in the Divine Reason, a "spark of Deity." Christian theologians, who found much in Plato's system that they could assimilate, also appropriated this ancient doctrine as to reason. Augustine applied it to explain the reception of supernatural truth and the divine illumination of the mind of man, and it coalesced with the Logos-doctrine of the Church. From Augustine and neoplatonism it was accepted by Descartes and so became entrenched in early modern philosophy. The existence of a *lumen naturale,* a faculty innate as instinct, but mediating necessary and eternal truths, was one of the tenets of rationalism and one that theologians were naturally inclined to adopt. Hence *a priori* theology, in the psychological as well as the logical sense of the phrase, flourished long Another feature of the rationalistic and *a priori* theory of knowledge is its tendency to identify knowledge and thought. Knowledge (of actuality) is pre-eminently

thought, but since the 18th century we have been compelled to recognize that it is also more. Further, the consistency of thought with itself was often confounded with validity—*i.e.*, with "holding of" actual things. But fiction can be consistent while not being truth about actual persons, and metageometries may be as consistent as Euclid without having any applicability to our world. Moreover, what were deemed to have been self-evident axioms, forming the basal principles of various sciences from mathematics to theology and purporting to be read off as necessary truths by pure reason, have in these latter days been accused of being either conventions, like the rules of a game, or disguised empirical inductions. These modern discoveries and the emergence of a genetic science of common or universal, as distinct from private or individual, experience have rendered tenet after tenet of the *a priori* school obsolete for many minds.

Turning now to the application of this method and type of philosophy to the sphere of theology, we may note that to it is due a large part of the content of the traditional conception of God and His attributes. From the patristic age to the modern period of philosophy philosophical theologians took over the concept of God as largely fashioned during the long development of religious thought, including the Hebrew thought in which Christianity has its roots And in Hebrew religion, the transcendent attribute of Jehovah is His holiness God is personal, not a cosmic force, interested in individuals, immanent in Nature and man But the Greek philosophers, who founded philosophical theology, had relatively little concern with such qualifications of Deity. Greek philosophy began as cosmology and ethics was an after-development. And Greek theology was rather an academic product than born of personal experience and life Hence, save for Plato's identification of God with the Good, it endowed God with what may roughly be called "the physical" attributes in a predominant degree. The Greek mind, not the Hebrew, is responsible for the attribute of infinity, perhaps for those of omnipotence and omniscience in their absolute and rigorous senses, and for the qualities of immutability and impassibility, the taking over of which by Fathers of the Church involved them in the difficult task of reconciling such attributes with the nature of a living Spirit. Some of the Greek theological ideas, *a priori* in character rather than derived from life and experience, proved to be a mould somewhat incongruous with the Hebrew-Christian content which philosophically-minded Christian doctors thrust into it It was at once too large and too small. If immutability means more than self-consistency, and impassibility more than freedom from human anger and corporeal passions, they cannot be predicates of a God of love and a Father of spirits. Like infinity, until that concept passes over into the idea of ethical perfection, they are derived from inert matter rather than active spirit and are quasimaterialistic or mathematical rather than spiritual and ethical conceptions "Infinity" has borne several distinct meanings, both in Greek and in later philosophy. Originally its sense seems to have been that of indeterminateness or being devoid of any particular characters, formless, indefinite and indefinable: in which case it is, of course, not predicable of any actual being. Then it came to mean the endless or limitless, what cannot be reached by successive acts of addition or division. Infinity, in this sense of the endless in time, space or number, is only relevant in mathematics; it can have no application to God, who is without parts or magnitude Lastly, "infinity" acquired the meaning of completeness, ethical perfection and immutability. Then, however, it became a redundant word; as properly used it can be dispensed with by theology.

Even more inapt to Christian or theistic theology than some of the Greek *a priori* concepts is the abstractive method of arriving at a conception of God, which passed, through Philo especially, from Greek thought to some of the Fathers of the Church. The rationalistic propensity to regard the most abstract conception as the ultimately real being, coupled with the formally intellectual tendency to oust from philosophy and theology not only the anthropomorphisms of vulgar thought but also the inalienable anthropic functions of human mentality, led to usage of "the negative way." That consists in repudiating all positive characterizations of God supplied by human analogies. It has aptly been described as a deification of the word "not." Everything, it is represented, that can be affirmed of the finite must be denied of the Infinite One. Thus God becomes conceived as an indeterminate absolute, ineffable and unknowable; the living Spirit is replaced by a pure idea. The Fathers favourable to this method, who even when abstract philosophers were also pastors and curators of Christian tradition, were saved from propounding these extravagances by a wholesome inconsistency. But Philo, gnostics, and neoplatonists, who took the negative way more seriously, found it necessary, in order to bridge the impassable gulf which they set between the Infinite One and the finite world, to invent powers, aeons and emanations.

The Empirical Method and Natural Theology.—The phrase "natural theology" has usually been a synonym for "rational theology"; *e.g.*, the natural theology of the English deists, who may aptly be described as rational theists, consisted of doctrines supposed to have been discerned by human reason, its first principles being self-evident, and its secondary doctrines being deduced from them, in accordance with the *a priori* principle, that so and so is because it must be. But it is convenient to give to "natural theology" a distinctive meaning. As a synonym for "rational theology" it is superfluous; while there is a theology derivable empirically from the study of Nature, man and human history, and consequently not "rational" and *a priori*, for which the title "natural" is the most appropriate. It will therefore be so used in the present context.

The possibility of a theology of this kind was recognized at least as early as the time of St. Paul, who wrote that "the invisible things of [God] from the creation of the world are clearly seen, being understood by *the things that are made*." But though theology is thus derivable, it must be added that it has not as yet been derived, at least not with anything like the completeness and system possessed by some of the rational theologies that have been forthcoming between the times of, say, Aristotle and Hegel Empiricism, in a nobler than its historical sense which degrades it to sensationism, yet awaits its master-mind comparable to a Plato or a Spinoza, hitherto, both in philosophy and theology, it has been represented but fragmentarily, and, if by able thinkers, scarcely by genius of the highest order. Some of the threads which await weaving into the texture of an empirically grounded philosophical theology by a future master-weaver are already within the common ken and may be briefly indicated.

It is admitted that theology rests on faith Faith, in the first instance, creates ideas, such as that of God, and believes in real or actual counterparts to them It claims to be knowledge, but is not knowledge or cannot be known to be knowledge, in the same sense that natural science is knowledge. Faith may issue in knowledge or it may not. The individual believer, whether a mystic or a non-mystic, may adopt, for the ordering of his own life, the attitude "I am certain." Therein he is invulnerable; but his faith will be a matter of personal biography and his certainty will be but subjective certitude or convincedness until reasons be forthcoming for taking the objects of his belief to be actual (as is the king of England) and not merely imaginal (as the mermaid) or purely ideal (as the line without breadth) Theology and philosophy are concerned with the knowability and the actuality of God and with the validity of statements about Him. Rational theology maintained that God's existence, etc., could be proved as coercively as a theorem in Euclid. Empirical theology denies that this is so, and empiricism asserts that knowledge, in that sense, is not forthcoming even as to the existence of other subjects or souls than one's own. Empiricism can also assert that what is called scientific knowledge and what are our most assured convictions as to the physical world rest ultimately on indemonstrable postulates or an act of faith, and observes that there is no more a rational cosmology than there is a rational theology. In both spheres verification is pragmatic and is very different from logical certification, which would only be forthcoming if science were composed of deductions from axioms, instead of inductions from facts. Thus, in the entire realm of actuality, as distinguished from that of the pure or ideal sciences, what, of courtesy, we

call knowledge is after all but probable belief. We can only be reasonable, not rational.

Such is the empirical account of the relation of faith to reason, theology to science and philosophy. It follows that no proof, in the most rigid sense, of the primary dogma of theism is possible. Such proof as may be had will consist in showing that theism is the most reasonable interpretation of the world and man, and in displaying the cumulative evidence for the assertion that the cosmos is due to the conspiration of innumerable causes and adaptations, by their united and reciprocal action, to issue in a general order of Nature, such as cannot reasonably be ascribed to fortuitousness but only to design by a supreme mind that must be intelligent and moral, the ground of the Good, the Beautiful and the True. Philosophical theology will thenceforward consist in the reinterpretation of the world and human history in terms of that metaphysical conclusion.

Theology Based on Other Grounds.—After rational theology received the classic criticism of Hume and Kant, attempts were made to establish theology on a new basis The old proofs having been shown to be either fallacious or insufficient, the theoretical knowledge-methods by which they had been mediated were renounced, as not the proper foundation of theology But the empirical procedure, seeking for grounds of reasonable belief wherewith intellectually to justify faith, did not commend itself to the generations which succeeded Kant In the 19th century the discovery of the deists that revealed religion presupposes natural religion was ignored, and Butler's suggestion, that what he vaguely called probability constituted our guide, was deemed inadequate. The latter line of thought was indeed pursued, without explicit awareness of the fact, by the numerous English writers who, from S T. Coleridge onwards, developed the doctrine that religious truth can only be judged and accepted by "the whole man," and not by man as merely intelligent. Recoil from discredited 18th century rationalism, however, did not direct itself to the empiricism represented by Locke, and perhaps more faithfully, in the theological sphere, by Butler. Confusing probability, as something pertaining to common or public beliefs and "knowledge," with acceptance as merely probable on the part of the individual believer, objectors generally submitted that ardent faith is not a weighing of probabilities, nor can faith be content to stake its vital convictions on what it merely deems probable

Of course the faithful man is certain, in the sense of being privately convinced; but what he is confident about may not have logical or scientific demonstrability from the point of view of objective or common knowledge. And it is the latter issue, not the mentality of this or that individual, with which theology is concerned. But inasmuch as this confusion of standpoints was prevalent, it is not surprising that efforts were forthcoming to find a new basis for theology such as should constitute it a science, yet vindicate subjective certitude. Schleiermacher appealed to immediate experience But it may perhaps be said that the immediacy of which he treated is but mediateness unrecognized. when he proceeded to draw out what was implicit in his fundamental immediate truths, he reveals the presupposing of a whole system of philosophy and science Another such attempt was that of Ritschl, who sought to make theology independent of the sciences of Nature and historical criticism, of metaphysics or theoretical (by which he seems to have meant rational) knowledge, grounding it on judgments of worth. That theology derives its arguments largely from considerations as to values is of course true. But these valuations must be appreciations of the actual, and so presuppose knowledge of the world and man, in order to yield any theistic argument The existence of a real object, such as God or heaven, cannot be inferred from the worth of an ideal object or from doctrines about such objects. An existential science, then, cannot be extracted from considerations as to worth alone. There is room, moreover, for nothing but private faith or blind hope in the realization and conservation of the valuable, until the universe has been found, by theoretical knowledge, at least not to be of such a nature as to involve extinction of the valuable. That the good *ought* to be conserved is irrelevant to whether it *will* be conserved, until we have established a reasonable belief in a good God. Thus it would again seem that theology can only claim to be reasonable belief and that it can only provide itself with reasonable belief by interpreting the actual world. Once severed from the kind of "knowledge" on which it is dependent, it is unable to find any criterion whereby to distinguish reasoned and reasonable belief from superstition, theology from rules for pious behaviour or for pious feeling towards objects that may be but fond imaginations.

Biblical and Dogmatic Theology.—Only a few words can be added here to what has been already said as to dogmatic and Biblical theology, subjects on which the special headings should be consulted. There is, of course, no one theology of the Old Testament. that collection of books, belonging to different times, is constituted a unity by its record of how Hebrew monotheism gradually developed during several centuries. It describes man's groping after God, which, from the theistic point of view, is but the converse side of God's progressive revelation of Himself to man, imparting knowledge of Himself or inspiring the pursuit of religious discovery, not by over-riding human faculties but by adaptation or condescension to them God, as a Christian Father expresses it, ever took man as he was, in order to make him what he was not. Thus was gradually reached the lofty and ethical conception of God and His relation to humanity which was presented by the great prophets. The Old Testament contains the history of God's preparation for the reception by humanity of the highest and fullest revelation of Himself in a human personality. The New Testament, again, contains the account of the impression produced by the life and teaching of Christ and the earliest extant interpretations of His Person. The relation of Christ to God came to be formulated in terms of the conception of incarnation; but though incarnation involves an event in "the fulness of time," the Incarnation has been by no means exclusively regarded by Christian doctors as a complete discontinuity or as but contingent on man's need of redemption. From antiquity there have been those who regard the Incarnation, on the one hand, as the last of many stages and, on the other, as part of the eternal counsel of God The doctrine of the Incarnation and that of the Trinity which is intimately bound up with it are the two dogmas that are most distinctive of the Christian type of theism; and they are the two which for the first five centuries figure most prominently in the development of the Church's doctrine In this connection it is interesting and important to observe that during this constructive period there was a considerable approach, within the Church, to that divergence as to philosophical method that has received notice in earlier sections of this article. The school of Alexandria was largely platonist in its theological conceptions; and, setting forth from the divinity of Christ as—in a sense—*a priori* datum or prior certainty, sought as best it could to account for Christ's human nature and to explain its union with the divine nature in one person The school of Antioch, on the other hand, was more empirical. It pursued the scientific or historical, rather than the allegorical, method of exegesis of Scripture and, in Christology, it set out from the observed facts about Christ as man, seeking how to conceive of His deity compatibly with them The Alexandrines cherished the metaphysical concepts of substance, etc , and spoke of the union of the two natures in Christ as "hypostatic"; the Antiochenes preferred to think in terms of the ethical and spoke of a "moral harmony" For better or for worse, the former school exerted the dominating influence in the final and oecumenical formulation of orthodoxy. It transmitted doctrines expressed in terms of philosophical conceptions which the modern mind sometimes evinces a desire to discard or supersede, on the ground that they do not take account of distinctions which, once emergent, cannot be ignored, and otherwise present difficulties which, unsuspected in the past, to-day are felt to be acute.

Returning to the particular dogmas of the Trinity and the Person of Christ, we may observe that in the case of the elaboration of the former of them the search was made for a conception of the Persons of the Triune God such as should avoid the implication that God is a divine society of several individuals and also the implication that the Persons are merely temporal rôles or

modes of God. In other words, the great doctors from Tertullian to Aquinas who have expounded Trinitarian doctrine were feeling for a mode of being intermediate between what can be denoted by a noun and what can be denoted by an adjective, such as an attribute or a relation. Since human experience knows of no such mode of being and the conception of it cannot be elucidated by any analogy, these teachers have recognized that, in the last resort, they were dealing with mystery or with what transcends the limits of the human mind to comprehend or to conceive And, shrinking more from tritheism than from modalism, they gave to the orthodox formulation of the doctrine of the Trinity a meaning which it is not easy to distinguish in essence from the rigidly monotheistic or monarchian conception of God as undifferentiated, save in respect of possessing a plurality of attributes or relations that are eternal and intrinsic and not merely temporary, as heresiarchs had asserted On the other hand the doctrine of the Person of Christ which received the consent of the universal Church implies that in Christ, as incarnate, there was but one subject—if this term of modern psychology accurately represents what was meant—viz, the Logos or pre-existent Son, and that our Lord's human nature was "impersonal" This would seem to involve a conception of the Trinity somewhat different from that contained in the dogma as just expounded, inasmuch as the Logos is now treated as an agent or subject and yet as distinct from God or the Father. Perhaps it is owing to a sense of discrepancy in this connection that recent thought has sometimes manifested a tendency to interpret the Incarnation of the Logos in terms of the notion of divine immanence in a human personality. From this point of view, "God was in Christ . . ." would better express the Incarnation-doctrine than "The Word became flesh." But the translation of these two fundamental Christian doctrines into terms of conceptions such as are serviceable in psychology and theology at the present day has not yet been accomplished.

Bibliography —Of the theology of ancient Greece a particular interpretation will be found in Edward Caird, *The Evolution of Theology in the Greek Philosophers* (2 vols. 1904). On the influence of Greek philosophy on early Christian thought, *see* C Bigg, *The Christian Platonists of Alexandria* (1886, new ed 1913). Of the theological thought of ancient and modern philosophers an account is given in J. Watson, *The Interpretation of Religious Experience* (vol. 1, 1912) The most important book on religious experience is the pioneer work of William James, *The Varieties of Religious Experience* (1902). For studies propaedeutic to philosophical theology and an empirical approach to theology, *see* F. R. Tennant, *Philosophical Theology* (1928). A concise account of the early development of dogmatic theology is contained in J. F. Bethune-Baker, *An Introduction to the early history of Christian Doctrine* (1903, 2nd ed. 1920) For further relevant literature *see* Theism, Faith, Dogma and articles on specific doctrines, etc. (F. R T.)

THEOPHANES, surnamed "the Confessor" (*c.* A D. 758–818), Greek ascetic, chronicler and saint, belonged to a noble and wealthy family and held several offices under Constantine V., Copronymus (741–775). He subsequently founded a monastery (τοῦ Μεγάλου Ἀγροῦ) near Sigriane. He took a strong position against the Iconoclastic policy of Leo V. and was imprisoned in Samothrace, where he died (818). He subsequently received the honours of canonization. He continued the Chronicle of George the Syncellus from the accession of Diocletian to the downfall of Michael I. Rhangabes (284–813). The work, although wanting in chronological accuracy, is of great value as supplying the accounts of lost authorities.

There is also extant a further continuation, in six books, of the *Chronicle* down to the year 961 by a number of mostly anonymous writers (called Οἱ μετὰ Θεοφάνην, Scriptores post Theophanem), who undertook the work by the instructions of Constantine Porphyrogenitus.

Editions of the *Chronicle:—Editio princeps*, J. Goar (1655); J. P. Migne, *Patrologia Graeca*, cviii; J. Classen in Bonn *Corpus Scriptorum Hist. Byzantinae* (1839–41); and C. de Boor (1883–85), with an exhaustive treatise on the ms. and an elaborate index; E. W. Brooks in *Byzantinische Zeitschrift*, 15, p. 578 *et seq.*

Editions of the *Continuation* in J. P. Migne, *Patr. Gr.*, cix., and writer in *Sitzungsberichte der philos.-philol. und der hist. Cl der k* by I. Bekker, Bonn *Corpus Scriptorum Hist. Byz.* (1838); on both works and Theophanes generally, *see* C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897); *Ein Dithyrambus auf Theophanes Confessor* (a panegyric on Theophanes by a certain *protoasecretis*, or chief secretary, under Constantine Porphyrogenitus) and *Eine neue Vita des Theophanes Confessor* (anonymous), both edited by the same writer in *Sitzungsberichte der Philos.-philol. und der hist. Cl. der k. bayer. Akad der Wissenschaften* (1896, pp 583–625; and 1897, pp. 371–399); Gibbon's *Decline and Fall* (ed. Bury, 1896–1900), v. p. 530.

THÉOPHILE, the name by which Théophile de Viau (or Viaud), French poet (1591–1626), is more commonly called. He was born in 1591, at Clairac, near Agen, and was educated at the Protestant college of Saumur. In 1612 he met Balzac, with whom he made an expedition to the Netherlands, which ended in a serious quarrel. On his return he seems to have been for two years a regular playwright to the actors at the Hôtel de Bourgogne. In 1615 he attached himself to Henry, duke of Montmorency (1595–1632), under whose protection he produced the tragedy of *Pyrame et Thisbé,* acted probably about 1617. This piece, written in the extravagant Spanish-Italian manner, was ridiculed by Boileau (Preface to his *Œuvres*, 1701). Théophile was a Huguenot and a freethinker, and had made unsparing use of his sharp wit in epigrams on the Church and on the government. In 1619 he was banished from Paris, but was allowed to return in the next year. He then served in that year in the campaign against the Huguenots, but in the autumn was an exile in England. He was recalled in 1621, and abjured Protestantism in 1622 In 1622 he had contributed four pieces to the *Nouveau Parnasse Satirique,* a miscellany of verse by many hands. In the next year a new edition appeared, with the addition of some licentious verse, and the inscription *par le sieur Théophile* on the title-page. Contemporary opinion justified Théophile's denial of this ascription, but the Jesuit father, François Garasse, published a tract against him entitled *La Doctrine curieuse* (1623) Théophile was again prosecuted. This time he fled from Paris, to the court of Montmorency, and was condemned in his absence (Aug 19, 1623) to death. On his flight to the border he was arrested, and imprisoned in the Conciergerie in Paris. He defended himself in an *Apologie au roi* (1625), and was liberated in September, his sentence being commuted to banishment for life Under Montmorency's protection he hid in Paris for some time, and subsequently accompanied his friend and patron to the south. He died in Paris on Sept 25, 1626.

Forty-two pamphlets on the prosecution of Théophile, written between the dates 1622 and 1626, are preserved in the Bibliothèque Nationale in Paris. The standard modern edition of the works of Théophile is that of Alleaume in the *Bibliothèque Elzévirienne* (2 vols 1856). Besides *Pyrame et Thisbé*, his works include a paraphrase, half verse, half prose, of the *Phaedo.* There are numerous French and Latin letters, his *Apologie*, a promising fragment of comic prose narrative, and a large collection of occasional verses, odes, elegies, stanzas, etc. *See* K Schirmacher, *Théophile de Viau* (Leipzig and Paris, 1897)

THÉOPHILUS, East Roman emperor (829–842), the second of the "Phrygian" dynasty, a pronounced iconoclast In 832 he issued an edict strictly forbidding the worship of images. His whole reign was occupied in war against the caliphs of Baghdad. (*See* Caliphate, especially sect. C., § 8.) This war was caused by Theophilus, who afforded an asylum to a number of Persian refugees. The Roman arms were at first successful; in 837 Samosata and Zapetra (Zibatra, Sozopetra), the birthplace of Motasim, were taken and destroyed. Eager for revenge, Motasim assembled a vast army, one division of which defeated Theophilus, who commanded in person, at Dasymon, while the other advanced against Amorium, the cradle of the Phrygian dynasty. After a brave resistance the city fell into Motasim's hands through treachery. Thirty thousand of the inhabitants were slain, and the city razed to the ground. Theophilus never recovered from the blow, and he died at the beginning of 842.

See Gibbon, *Decline and Fall*, chaps. 48 and 52; F. G. Schlosser, *Geschichte der bilderstürmenden Kaiser* (1812); G. Finlay, *History of Greece*, ii. (1877), p 142; G. F. Hertzberg, *Geschichte der Byzantiner und des osmanischen Reiches*, bk. i. (Berlin, 1883); H. Gelzer, "Abriss der byzantinischen Kaisergeschichte" in C. Krumbacher's *Geschichte der byzantinischen Literatur* (2nd ed., 1897); and authorities under Roman Empire, Later. On the early campaigns against the Arabs *see* J. B. Bury, in *Journ. Hell. Stud.* xxix., 1909, pt. i.

THEOPHRASTUS, the successor of Aristotle in the Peripatetic school, a native of Eresus in Lesbos, was born *c.* 372 B.C. His original name was Tyrtamus, but he later became known by the nickname "Theophrastus," given to him, it is said, by Aristotle to indicate the grace of his conversation. After receiving his first introduction to philosophy in Lesbos from one Leucippus or Alcippus, he proceeded to Athens, and became a member of the Platonic circle. After Plato's death he attached himself to Aristotle, and in all probability accompanied him to Stageira. Aristotle in his will made him guardian of his children, bequeathed to him his library and the originals of his works, and designated him as his successor at the Lyceum on his own removal to Chalcis. Theophrastus presided over the Peripatetic school for 35 years, and died in 287 B.C.

The most important of the works of Theophrastus are two large botanical treatises, *On the History of Plants,* in nine books, originally ten, and *On the Causes of Plants,* in six books, originally eight, which constitute the most important contribution to botanical science during antiquity and the middle ages. We also possess in fragments a *History of Physics,* a treatise *On Stones,* and a work *On Sensation,* and certain metaphysical Ἀπορίαι, which probably once formed part of a systematic treatise. The writings of Theophrastus are accessible in the Teubner series.

The *Ethical Characters* (Ἠθικοὶ χαρακτῆρες) consist of brief, vigorous and trenchant delineations of moral types, which give a most valuable picture of the life of his time. They form the first recorded attempt at systematic "character" writing. The *Ethical Characters* was edited by Casaubon in 1592 and translated by La Bruyère (1688–89); the best modern translation (with introduction and notes) is that of Sir Richard Jebb (1870; rev. ed. J. E. Sandys, 1909).

BIBLIOGRAPHY.—A good account of Theophrastus is found in E. Zeller, *Aristotle and the Earlier Peripatetics* (Eng. trans. B. F. C. Costelloe and J. H. Muirhead, 1897). For his astronomical work, *see* ASTRONOMY (Historical Section) and for the botanical works, J. Berendes, *Die Pharmacie bei den alten Culturvölkern* (vol. i., 1891). *See* also G. S. Gordon, *Theophrastus and his Imitators* (1912).

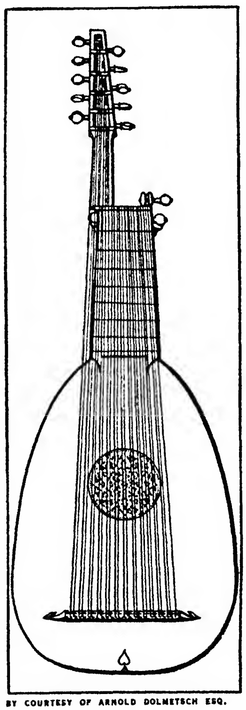
THEOPOMPUS (380 B.C.), Greek historian and rhetorician, was born at Chios about 380 B.C. In early youth he seems to have spent some time at Athens, along with his father, who had been exiled on account of his Laconian sympathies. Here he became a pupil of Isocrates, and rapidly made great progress in rhetoric. We are told that Isocrates used to say that Ephorus required the spur but Theopompus the bit (Cicero, *Brutus,* 204). At first he appears to have composed epideictic speeches, in which he attained to such proficiency that in 352–351 he gained the prize of oratory given by Artemisia (*q.v.*) in honour of her husband, although Isocrates was himself among the competitors. It is said to have been the advice of his teacher that finally determined his career as an historian—a career for which he was peculiarly qualified owing to his abundant patrimony and his wide knowledge of men and places. Through the influence of Alexander, he was restored to Chios about 333, and figured for some time as one of the leaders of the aristocratic party in his native town. After Alexander's death he was again expelled, and took refuge with Ptolemy in Egypt, where he appears to have met with a somewhat cold reception. The date of his death is unknown.

The works of Theopompus were chiefly historical, and are much quoted by later writers. They included an *Epitome of Herodotus's History* (the genuineness of which is doubted), the *Hellenics* (Ἑλληνικά, Ἑλληνικαὶ ἱστορίαι), the *History of Philip* (Φιλιππικά), and several panegyrics and hortatory addresses, the chief of which was the *Letter to Alexander.* The *Hellenics* treated of the history of Greece, in 12 books, from 411 (where Thucydides breaks off) to 394—the date of the battle of Cnidus (*cf.* Diod. Sic., xiii. 42, with xiv. 84). Of this work only a few fragments were known up till 1907. The papyrus fragment of a Greek historian of the 4th century B.C., discovered by B. P. Grenfell and A. S. Hunt, and published by them in *Oxyrhynchus Papyri,* vol. v. (1908), has been recognized by Ed. Meyer, U. von Wilamowitz-Moellendorff and G. Busolt as a portion of the *Hellenics.* This identification has been disputed, however, by F. Blass, J. B. Bury, E. M. Walker and others, most of whom attribute the fragment, which deals with the events of the year 395 B.C. and is of considerable extent, to Cratippus (*q.v.*). A far more elaborate work was the Φιλιππικά in 58 books. In this Theopompus narrated the history of Philip's reign (360–336), with digressions on the names and customs of the various races and countries of which he had occasion to speak, which were so numerous that Philip V. of Macedon reduced the bulk of the history from 58 to 16 books by cutting out those parts which had no connection with Macedonia. It was from this history that Trogus Pompeius (of whose *Historiae Philippicae* we possess the epitome by Justin) derived much of his material.

BIBLIOGRAPHY.—Fragments in C. Müller, *Frag. Hist. Graec.,* i.; monograph by A. J. Pflugk (1827), and a good account in W. Mure, *Language and Literature of Ancient Greece* (1850–57), v. pp. 509–529. *See* also GREECE: *Ancient History,* Authorities. A complete edition of the fragments of Theopompus and of Cratippus has been published by the Clarendon Press, Oxford (1909), containing the fragment of the new historian. For a discussion of the authorship of this fragment see *Oxyrhynchus Papyri* (1908), vol. v., pp. 110–242; G. Busolt, *Hermes* (1908), pp. 255–285 (*Der Neue Historiker und Xenophon*); E. M. Walker, *Klio* (1908) ("Cratippus or Theopompus"); W. A. Goligher, *English Historical Review,* vol. xxiii. pp. 277–282 ("The New Greek Historical Fragment"); A. von Mess, *Rheinisches Museum* (1908), pp. 370–391 ("Die Hellenica von Oxyrhynchos").

(E. M. WA.)

THEORBO, the large double-necked bass lute much used during the 16th and 17th centuries as general bass in the orchestra. The body of the theorbo was constructed on the same principles as that of the lute. The theorbo was made in two sizes, the ordinary instrument measuring about 3ft. 6in., and the Paduan, also known as archlute, about 5 feet. The chitarrone, or Roman theorbo, was the largest of all, a contrabass lute in fact, and frequently stood over 6ft. high. (*See* BARBITON; LUTE.)



BY COURTESY OF ARNOLD DOLMETSCH ESQ.
THE THEORBO

THEOREM, a term used in mathematics to represent a proposition which is to be demonstrated. In geometry, a proposition is commonly considered as a problem (a construction to be effected) or a theorem (a statement to be proved). For example, the statement: "If two lines intersect, each pair of vertical angles are equal" is a theorem. The so-called "Fundamental Theorem" of algebra asserts that every rational integral equation has at least one root. The Greeks also recognized a proposition lying between a theorem and a problem, the porism (*q.v.*). (*See* also FERMAT'S THEOREM; BINOMIAL THEOREM; REMAINDER THEOREM.)

THEORY, in logic and science, is a term used in various, though connected, meanings. Sometimes it is used as synonymous with hypothesis, that is, to denote any tentative explanation of phenomena. Sometimes it is restricted to explanations that have already passed beyond the stage of mere hypotheses by having received a considerable amount of verification. Sometimes, again, the term theory is simply contrasted with "practice" or "practical application," and will then include any kind of explanation, be it hypothetical or fully established. Lastly, the term is sometimes restricted to the most comprehensive explanation (hypothetical

or verified and established) as contrasted with the less comprehensive laws or explanations comprised under them and deducible from them. In this sense we speak of the *theory* of gravitation, but of Kepler's three *laws* of planetary motion, and of Boyle's *law*, but of the dynamic *theory* of gases. This last usage is perhaps the best. *See* A Wolf, *Essentials of Scientific Method* (1928).

THEOSOPHY, a term used to denote those forms of philosophic and religious thought which claim a special insight into the Divine nature and its constitutive moments or processes (from Gr. θεός, god and σοφία, wisdom). Sometimes this insight is claimed as the result of the operation of some higher faculty or some supernatural revelation to the individual; in other instances the theosophical theory is not based upon any special illumination, but is simply put forward as the deepest speculative wisdom of its author But in any case it is characteristic of theosophy that it starts with an explication of the Divine essence, and endeavours to deduce the phenomenal universe from the play of forces within the Divine nature itself

General Theory.—Theosophy is thus differentiated at once from all philosophic systems which attempt to rise from an analysis of phenomena to a knowledge, more or less adequate, of the existence and nature of God In all such systems, God is the *terminus ad quem,* a direct knowledge of whom is not claimed, but who is, as it were, the hypothesis adopted, with varying degrees of certainty in different thinkers, for the explanation of the facts before them. The theosophist, on the other hand, is most at his ease when moving within the circle of the Divine essence, into which he seems to claim absolute insight This, however, would be insufficient to distinguish theosophy from those systems of philosophy which are sometimes called "speculative" and "absolute," and which also in many cases proceed deductively from the idea of God In a wide sense the system of Hegel or the system of Spinoza may be cited as examples of what is meant. Both thinkers claim to exhibit the universe as the evolution of the Divine nature; so much is involved, indeed, in the construction of an absolute system. But in such systems the known universe—the world of experience—is nowhere transcended; God is really no more than the principle of unity immanent in the whole Hence, while the accusation of pantheism is frequently brought against these thinkers, the term theosophical is never used in their regard. A theosophical system may also be pantheistic, in tendency if not in intention; but the transcendent character of its Godhead definitely distinguishes it from the speculative philosophies which might otherwise seem to fall under the same definition An historical survey shows, indeed, that theosophy generally arises in connection with religious needs, and is the expression of religious convictions or aspirations. Accepting the testimony of religion that the present world lies in wickedness and imperfection, theosophy faces the problem of speculatively accounting for this state of things from the nature of the Godhead itself. It is thus in some sort a mystical philosophy of the existence of evil; or at least it assumes this form in some of its most typical representatives. The term Mysticism (*q v*) has properly a practical rather than a speculative reference; but it is currently applied so as to include the systems of thought on which practical mysticism was based Thus, to take only one prominent example, the profound speculations of Meister Eckhart (*q v*) are always treated under the head of Mysticism, but they might with equal right appear under the rubric Theosophy. In other words, while an emotional and practical mysticism may exist without attempting philosophically to explain itself, speculative mysticism is in current usage almost another name for theosophy.

In the above acceptation of the term, the neoplatonic doctrine of emanations from the supra-essential One, the fanciful emanation-doctrine of some of the gnostics (the aeons of the Valentinian system, for example), and the elaborate esoteric system of the Kabbalah, to which the two former in all probability largely contributed, are generally included under the head of theosophy. In the two latter instances there may be noted the allegorical interpretation of traditional doctrines and sacred writings which is a common characteristic of theosophical writers. Still more typical examples of theosophy are furnished by the mystical system of Meister Eckhart and the doctrine of Jacob Boehme (*q v*), who is known as "the theosophist" *par excellence* Eckhart's doctrine asserts behind God a predicateless Godhead, which, though unknowable not only to man but also to itself, is, as it were, the essence or potentiality of all things. From it proceed, and in it exist, the three persons of the Trinity, conceived as stadia of an eternal self-revealing process. The eternal generation of the Son is for Eckhart equivalent to the eternal creation of the world. But the sensuous and phenomenal, as such, so far as they seem to imply independence of God, are mere privation and nothingness; things exist only through the presence of God in them, and the goal of creation, like its outset, is the repose of the Godhead The soul of man, which as a microcosmos resumes the nature of things, strives by self-abnegation or self-annihilation to attain this unspeakable reunion (which Eckhart calls being "buried" in God). Regarding evil simply as privation, Eckhart does not make it the pivot of his thought as was afterwards done by Boehme; but his notion of the Godhead as a dark and formless essence is a favourite thesis of theosophy.

Boehme was indebted not only to mystical theology but also to the writings of Paracelsus This circumstance is not accidental, but points to an affinity in thought The nature-philosophers of the Renaissance, such as Nicolaus Cusanus, Paracelsus, Cardan and others, curiously blend scientific ideas with speculative notions derived from scholastic theology, from neoplatonism and even from the Kabbalah Hence it is customary to speak of their theories as a mixture of theosophy and physics, or theosophy and chemistry, as the case may be Boehme offers us a natural philosophy of the same sort As modern theosophy has nourished itself almost in every case upon the study of his works, his dominating conceptions supply us with the best illustration of the general trend of this mode of thought His speculation turns, as has been said, upon the necessity of reconciling the existence and the might of evil with the existence of an all-embracing and all-powerful God, without falling into Manichaeism on the one hand, or, on the other, into a naturalistic pantheism that denies the reality of the distinction between good and evil He faces the difficulty boldly, and the eternal conflict between the two may be said to furnish him with the ground-principle of his philosophy. It is in this connection that he insists on the necessity of the Nay to the Yea, of the negative to the positive. Eckhart's Godhead appears in Boehme as the abyss, the eternal nothing, the essenceless quiet (*Ungrund* and *Stille ohne Wesen* are two of Boehme's phrases). But, if this were all, the Divine Being would remain an abyss dark even to itself In God, however, as the condition of His manifestation, lies, according to Boehme, the "eternal nature" or the *mysterium magnum*, which is as anger to love, as darkness to light, and, in general, as the negative to the positive. This principle (which Boehme often calls the evil in God) illuminates both sides of the antithesis, and thus contains the possibility of their real existence By the "Qual" or torture, as it were, of this diremption, the universe has qualitative existence, and is knowable. Even the three persons of the Trinity, though existing *idealiter* beforehand, attain reality only through this principle of nature in God, which is hence spoken of as their *matrix*. It forms also the matter, as it were, out of which the world is created; without the dark and fiery principle, we are told, there would be no creature. Hence God is sometimes spoken of as the father, and the eternal nature as the mother, of things. Creation (which is conceived as an eternal process) begins with the creation of the angels. The subsequent fall of Lucifer is explained as his surrender of himself to the principle of nature, instead of dwelling in the heart of God He sought to make anger predominate over love; and he had his will, becoming prince of hell, the kingdom of God's anger, which still remains, however, an integral part of the Divine universe

Schelling's *Philosophical Inquiries into the Nature of Human Freedom* (1809) is almost entirely a reproduction of Boehme's ideas, and forms, along with Baader's writings, the best modern example of theosophical speculation. In his philosophy of identity Schelling (*q.v*) had already defined the Absolute as pure indiffer-

ence, or the identity of subject and object, but without advancing further into theogony. He now proceeded to distinguish three moments in God, the first of which is the pure indifference which, in a sense, precedes all existence—the primal basis or abyss, as he calls it, in agreement with Boehme. But, as there is nothing before or besides God, God must have the ground or cause of His existence in Himself. This is the second moment, called nature in God, distinguishable from God, but inseparable from Him. It is that in God which is not God Himself, it is the yearning of the eternal One to give birth to itself. This yearning is a dumb unintelligent longing, which moves like a heaving sea in obedience to some dark and indefinite law, and is powerless to fashion anything in permanence But in correspondence to the first stirring of the Divine existence there awakes in God Himself an inner reflective perception, by means of which—since no object is possible for it but God—God beholds Himself in His own image In this, God is for the first time as it were realized, although as yet only within Himself This perception combines, as understanding, with the primal yearning, which becomes thereby free creative will, and works formatively in the originally lawless nature or ground In this wise is created the world as we know it. In every natural existence there are, therefore, two principles to be distinguished—first, the dark principle, through which the being in question is separated from God, and exists, as it were, in the mere ground; and, secondly, the Divine principle of understanding The first is the particular will of the creature, the second is the universal will In irrational creatures the particular will or greed of the individual is controlled by external forces, and thus used as an instrument of the universal. But in man the two principles are consciously present together, not, however, in inseparable union, as they are in God, but with the possibility of separation This possibility of separation is the possibility of good and evil. In Boehme's spirit, Schelling defended his idea of God as the only way of vindicating for God the consciousness which naturalism denies, and which ordinary theism emptily asserts Among thinkers on the same lines, but more or less independent, Molitor is perhaps the most important Swedenborg (*q v*) is usually reckoned among the theosophists.

THE THEOSOPHICAL SOCIETY

The term "theosophy" has in recent years obtained a wide currency in certain circles as denominating the beliefs and teachings of the Theosophical Society. This society was founded in the United States in 1875 by Madame H. P. Blavatsky (*q.v*), in connection with Col. H. S Olcott and others. Col Olcott remained president of the original society till his death in 1907, when he was succeeded by Mrs Annie Besant But soon after the death of Madame Blavatsky (1891) a split took place which led to the formation of a separate organization in America under the leadership of William P Judge. The main objects of this society, as originally propounded, were:

(1) To establish a nucleus of the universal brotherhood of humanity;

(2) to promote the study of comparative religion and philosophy; and

(3) to make a systematic investigation into the mystic potencies of life and matter, or what is usually termed "occultism."

Mahatmas.—According to Madame Blavatsky's original statements this wisdom has been transmitted through the ages as a secret doctrine or esoteric teaching by a brotherhood of adepts or Mahatmas scattered through the world but in close relation with one another. With a certain group of these in Tibet she claimed to be in communication. In such adepts the spiritual nature is supposed to have been so developed that the body has become the ductile instrument of the intelligence and they have thus gained a control over natural forces which enables them to bring about results that appear to be miraculous.

Religious Aspect.—The most characteristic feature of this modern "theosophical" teaching is the belief in reincarnation, and here again the close connection with Indian thought is observable. The succession of earthly lives through which the spirit advances to its goal is interpreted in strict accordance with the Brahmanic and Buddhistic doctrine of Karma. First introduced in the Upanishads as the great secret which solves the problem of human destiny, Karma is in a sense the logical origin of all Indian thought. It expresses the inexorable law of moral causation—whatsoever a man soweth that shall he also reap—and this law is represented as fulfilling itself in the life-history of each individual agent. The consequences of a man's actions in his present life are reaped by the agent on earth in a fresh incarnation. Hence the saying, "A man is born into the world he has made." The theory of Karma is thus primarily an explanation of a man's lot in the present life as determined by his own actions in a series of previous lives If it is true that whatsoever a man soweth that shall he also reap, it must be equally true that whatsoever a man reaps that he must also have sown. The doctrine is thus in its essence a vindication of cosmic justice in face of the perplexities caused by the apparent disregard of moral considerations in the distribution of happiness and misery in the present life, and it is in this sense that it is accepted and applied by theosophists. (A. S. P -P.)

THÉOT, CATHERINE (d. 1794), French visionary, was born at Barenton (Manche). In Robespierre her followers saw the redeemer of mankind and preparations for his initiation were put in train. Catherine, with others, was arrested and imprisoned. The accused were ultimately acquitted, Catherine herself having died in prison on Sept 1, 1794

THEOTOCOPULI, DOMENICO (*c* 1542–1614), known as El Greco, Spanish painter. He was born in Candia, Crete. His Greek name, Domenicos Theotocopoulos, was changed in Italy and Spain into Domenico and Dominico Theotocopuli, and he thus signed his name in Greek characters. We first hear of him in a letter written by the miniaturist, Julio Clovio, to the cardinal Alessandro Farnese, dated Rome, Nov. 16, 1570. "There has arrived in Rome a young man from Candia, a pupil of Titian, who, I think, is a painter of rare talent. . . . He has painted a portrait of himself which is admired by all the painters in Rome I should like him to be under the patronage of your reverend lordship without any other contribution towards his living than a room in the Farnese Palace" Unfortunately, the portrait here mentioned is lost. Works of this early period are. the portrait of Clovio (Naples museum), "The Healing of the Blind," of which there are two versions (Museums of Parma and Dresden) and "Christ driving the Traders from the Temple," of which there are versions in the collection of Sir Herbert Cook, Richmond, in the Minneapolis museum and in the Frick collection, New York, the last of a somewhat later period Though a pupil of Titian, he was influenced by Tintoretto and the Bassanos, and while in Rome he studied Michelangelo. In the picture at Minneapolis, Titian and Michelangelo are introduced with Clovio in the lower right hand corner.

We next hear of Theotocopuli in Toledo, at work in the church of Santo Domingo el Antiguo, rebuilt in 1575 on the outskirts of the city. Here he designed the architecture and sculpture of a composite altar in Venetian style and painted the pictures for it The centrepiece (now in the Chicago Art institute) representing "The Assumption of the Virgin," is a free adaptation to Spanish surroundings of Titian's masterpiece, in the Frari at Venice, and is painted with daring and intensity, in a rich, deep colour scheme. Flanking it, and still in their original position, are the imposing figures of St. John the Baptist and St. John the Evangelist. On the side altars are "The Adoration of the Shepherds" and "The Resurrection," while "The Trinity" with its Michelangelesque "The dead Christ in the Arms of God the Father" is now in the Prado. Toledo had never seen such art before; and in 1577, the year when "The Assumption" was completed, he was asked by the chapter of Toledo cathedral to paint the chief picture for their new sacristy. He chose as his subject "The Stripping of Christ before the Crucifixion" (El Espolio). Christ's impressive figure in the centre stands out among a crowd of executioners whose brutality contrasts with the Gentle Marys in the lower part of the picture The whole surface of the canvas is compactly filled. As in Michelangelo's blocks of marble, there are no open views, no empty spaces The cold tone of the painting contrasts with the glowing Venetian

colour of his earlier work, and is distinctly Spanish. The picture was completed in 1579. The chapter, finding its price too high, had it valued by artists, who decided in Theotocopuli's favour. Whereupon the chapter demanded the removal from the picture of "certain improprieties" such as the presence of the Marys below the Christ. The artist, being threatened with imprisonment, at length gave in; but somehow the picture was left as it was. It constitutes the masterpiece of his early period in Spain. He had lavished all his art on it in the hope that the doors of the Escorial might open to him, and he seemed to succeed, for Philip II. asked him to provide an altarpiece for his church in the spring of 1580 In "St. Maurice and his Legion," El Greco realized a new form of expression, for which he had been searching since his arrival in Spain. Withdrawn as he was from the example of the great Italian masters, he was thrown on himself. His Byzantine origin made itself felt in the swinging rhythm of his design, the fervent religiosity of 16th century Spain in the extreme expression of feeling.

However, when the completed work was submitted to the king he failed to understand the strange new treatment, and though it remained at the Escorial, it was not placed over the appointed altar. His next important work was the famous "Burial of Count Orgaz" (El Enterrio), for the church of St. Tomé at Toledo. It treats of a miracle Don Gonzalo Ruiz, governor of Orgaz, had, during his lifetime, professed devotion to St. Augustin and St. Stephen, who descended from heaven when his body was about to be buried in the church of St Tomé, which he had rebuilt, and laid him to rest to the wonder of the attending clergy and mourners, who are shown in a long row of vivid Spanish heads, placed like a frieze horizontally across the picture The upper portion of the painting depicts the reception of the court in heaven The supernatural world is joined to the realistic scene below by the harmonious lines of a geometric design recalling the tracery of a Gothic window. Again the price of the picture was the cause of a lawsuit El Greco henceforth seemed wholly occupied by his imaginative vision All elements of secondary value are discarded, and everything is subordinated to the realization of a rhythmical unity. In 1590 he completed, for the church of Dona Maria de Aragon at Madrid, an altarpiece with subjects from the life of Christ. Three pictures in the Prado representing "The Crucifixion," "The Resurrection" and "The Baptism," came from this church. An "Annunciation" at Villanueve y Cetru, formerly in the Prado, probably also belonged to this group Here colour and form are used as a means of emphasizing dramatic expression, with a result that, to many, is exaggeration and distortion The figures are elongated, the limbs twisted, and strange streaks of light flash across. The artist does not represent nature as it is, but uses it for his own ends. Here is restless religious strife, tumult, agony and mystic absorption. His contemporaries thought he had gone mad; others explained that he was suffering from astigmatism.

In 1597 followed the works for the chapel of San José at Toledo, of which "The Coronation of the Virgin" and "The St. Joseph" are still in their original place over the high altar, and "The St. Martin" and "The Virgin with Saints" are in the Widener collection at Philadelphia. Fewer figures are introduced, the colouring is silvery, the style severer and simplified. The same sober tendency is displayed in the paintings for the hospital of the Caridad at Illeseas, where "The San Idelfonso" combines poetry with realism in the interpretation of a Spanish legend. Other works of this period are: "The Dream of Philip II" and the "St. Francis," "St. Peter" and "St. Eugene" in the Escorial, and the splendid portrait of the Inquisitor, Neno Guevara (Havemeyer collection, New York), which seems to anticipate Velazquez's "Innocent X."

The most representative work of the closing stage, characterized by an intensification of his imaginative qualities, is "The Assumption," in the church of San Vicente at Toledo, completed in 1613, a few months before his death. It is a powerful and original composition showing the Virgin rising through the air among clouds of angels. Other important works of the late period are "The St. Bernard" (1603) and "The Plan of Toledo," in the Greco museum at Toledo; "The Pentecost," in the Prado; "The Laocoön" in Munich, and his last work, "The Baptism" at the Hospital of Tavera. El Greco anticipates imaginative landscape painting of later periods in the romantic representation of "Toledo in a Storm" (Havemeyer collection) where the old city, with its Alcázar and its cathedral is seen towering over the ravine of the Tajo against a thundery sky. Another late work is the fine portrait of Fray Hortensio Felix Paravicino at Boston. The Prado possesses a number of portraits painted at various times. Though few of his sitters are known to us by name, they are evidently all eminent men, of proud and distinguished race, types unchanged in Toledo to-day. These austere heads, with pointed beards resting on white ruffs, emerge from a sombre background and are modelled in cool tones. The eyes are full of inward life and reserve, the hands white and sensitive. As a painter of women, El Greco produced two masterpieces; "The Lady with the Flower," in the collection of Sir J. Stirling Maxwell, and "The Lady with the Mantilla" in the Johnson collection, Philadelphia. The portrait of an old man in the Metropolitan Museum, New York, passes as a self-portrait of the artist. Palomino states that Velazquez greatly admired El Greco's portraits, and there can be no doubt that he learned much from his predecessor.

El Greco had but few pupils, among them Maino and Tristan; they were unable to live up to his standard. Giuseppe Martinez explains: "None cared to follow his capricious and extravagant style, which was only suitable to himself." His son, Jorge Manuel, painter, sculptor and architect, born in 1578, worked with him, carrying out the paintings, which he left unfinished. The mother's name is given as Dona Jeronima de las Cuevas, but it is not stated that she was El Greco's wife. El Greco died at an advanced age, and was interred like a noble in the church of Santo Domingo el Antiguo on April 7, 1614, all Toledo mourning his death. When dangerously ill, he made his son universal heir, and gave him power to make his will. He left 115 finished paintings, 15 sketches, 4 grisailles and 150 drawings. Many of the pictures were replicas; the drawings no longer exist. There is but one authentic drawing by him, in the Biblioteca Nacional (Madrid). From his will we may draw inferences about his mode of life. He occupied 24 rooms of a palace of the Marques de Villena, once situated in the Paseo del Transito, on the edge of the cliff overlooking the Jajo, near the present Greco museum. He owned a good library of Greek books, including Homer, Aristotle, Plutarch; also editions of Tasso, Petrarch and Ariosto, and numerous volumes on architecture. Pacheco, who visited the painter in 1611, says that he was a great philosopher given to witty sayings, a sculptor and architect as well as a painter. He speaks of a cupboard, in which were models in clay which he made use of in his pictures, and says he saw the originals of all that he had painted in his life, painted in oils on smaller canvases (*Arte de La Pintura*). The great orator, F. Ortensio, Paravicino, and the celebrated poet, Luis de Gongona, wrote sonnets in his memory. A quotation from the writings of St. Theresa, the mystic of Spain, who was his contemporary, will help to explain the trend of El Greco's art. "I see a white and a red of a quality as one finds nowhere in nature, for they shine more brightly than the colours we perceive; and I see pictures, as no painter has yet painted, whose models one finds nowhere in nature; and yet they are nature itself, and life itself, and the most perfect beauty imaginable." Forgotten for centuries, Greco's art has only recently come into its own. It makes a strong appeal to the younger artists of the day. Manet was already a great admirer, the followers of Cézanne lay special claims on him as a forerunner, and Expressionists search for the principles, determined emphasis and distortion of form in his works.

PAINTINGS OF DOMENICO THEOTOCOPULI (EL GRECO) 1542–1614

1. "Christ Driving the Money Changers from the Temple," one of El Greco's early paintings now owned by the Minneapolis Institute of Art
2. Another painting of "Christ and the Money Changers," showing interesting contrast in style; now in the possession of Aaron Naumburg
3. "St. Peter," painted near the end of the 16th century, owned by Phillips Memorial Gallery, Washington
4. "Saint Ildefonso" combines poetry with realism, painted for the hospital of the Caridad of Illescas. A sober tendency is displayed in this painting now belonging to Andrew W. Mellon
5. "St. Dominic," one of the well known paintings of El Greco, now owned by John Nicholas Brown

THERA, the southernmost island of the Sporades, now called Santorin (*q.v.*), but known as Thera until after the Fourth Crusade, when it became part of the duchy of the Archipelago.

THERALITE, in petrology, a group of plutonic rocks built up of basic plagioclase (labradorite), nepheline, and a titaniferous augite. The name is derived from θηρᾶν, to pursue, as its discovery was looked forward to as completing the series of basic rocks containing nepheline as an essential constituent.

Olivine, an alkali-amphibole, biotite and orthoclase may be present as subordinate constituents. With the exception of nepheline and orthoclase, the minerals of theralites are usually in well shaped crystals. Nepheline itself may be largely represented by secondary zeolites. Theralites are of comparatively rare occurrence. They are known from the Bohemian alkali province, as at Duppau, in association with shonkinite, at the Katzenbuckel (South-east Tirol), together with pulaskite and foyaite in the Serra de Monchique (Portugal), at Umptek (on the White sea), and among the Carboniferous intrusions of Ayrshire (Scotland).

Closely related to the theralites are the teschenites (from Teschen, Moravia). In place of nepheline these rocks contain primary analcime, but types containing both nepheline and analcime are known. In central Scotland, around Edinburgh and Glasgow, teschenites are abundant, forming thick sills intrusive into the Carboniferous rocks. Teschenites are sometimes ophitic, and show transitions to olivine-dolerites on the one hand and to picrites on the other. The rock known as lugarite (from Lugar, Ayrshire) is a related type containing small amounts of plagioclase but abundant analcime; nepheline is present in subordinate amount.

Other rocks related to the theralites are the essexites and shonkinites. The former are characterized by dominant plagioclase, subordinate orthoclase, and green augite, hornblende, biotite and olivine. Nepheline also occurs by no means uncommonly. By increase in the proportion of nepheline the essexites pass into theralites. Essexites occur, together with nepheline syenite, in Essex county, Mass., at Mount Royal near Montreal, in southern Norway (Oslo district), at Rongstock, Bohemia, and among the carboniferous teschenites near Edinburgh and in the Campsie hills, Stirlingshire. The shonkinites are melanocratic rocks of much rarer occurrence. Augite and orthoclase are the prime constituents, but plagioclase, barkevikite, olivine, biotite and variable amounts of nepheline are present. At Shonkin Sag, in the Highwood mountains of Montana, shonkinite forms the greater part of a stratified laccolith passing at the border into a peculiar basic rock described as a leucite-basalt porphyry.

Shonkinites are also known from Ontario, British Columbia, and the East Indies (Celebes, Timor). (C. E. T.)

THERAMENES (d. 403 B.C.), Athenian statesman, was the adopted son of Hagnon, a prominent conservative who in 430 impeached Pericles, and after the Sicilian expedition became one of the ten *probuli* (πρόβουλοι, commissioners) appointed to devise economies in the administration. Theramenes formulated a new party-cry, "the constitution of our fathers." It was no doubt largely due to his advocacy that the *probuli,* strengthened by further members, were commissioned to draft new measures on behalf of the public safety and to examine Cleisthenes' "ancestral code." (*See* BOULE and GREECE: *History.*)

Late in 405 Theramenes went as plenipotentiary to Lysander (*q.v.*) to obtain peace terms (*see* PELOPONNESIAN WAR); after long negotiations he proceeded to Sparta and arranged a settlement which the Athenians ratified (April 404). In spite of this peace the disorder in Athens did not abate. At the instance of Critias, Theramenes was arraigned for treason and, although he successfully repelled the denunciation, he was led away by violence and forced to take poison.

See Plutarch, *Cicero,* chap. 59; Cicero, *de Oratore,* iii. 16, 59; Wilamowitz-Möllendorff, *Aristoteles und Athen* (Berlin and Leipzig, 1893), ii. p. 113 *sqq.;* E. Meyer, *Forschungen zur alten Geschichte* (Halle, 1899), ii. pp. 406 *sqq.;* B. Perrin in *American Historical Review,* ix. (1904), pp. 649–69.

THERAPEUTAE, an ancient sect of ascetics believed to have lived in the vicinity of Alexandria and near Lake Mareotis. They are mentioned in Philo's *De Vita Contemplativa,* and are characterized as being unusually severe in their discipline and mode of life. Abjuring money rather than matter, the Therapeutae lived a secluded life, each member keeping to his own dwelling rather than mingling together in common fellowship.

Chief among the institutions of this sect was a festival held every seven weeks and at the culmination of which, bands of women and men danced and sang throughout the night. On every Sabbath they gathered for worship jointly. Their entire lives were devoted strictly to meditation and prayer. They despised all forms of avarice.

As the result of Philo being the only authority regarding the life and existence of the Therapeutae, there are a number of controversial questions concerning the sect. Some authorities regard the Therapeutae as a Christian order due to the similarity between their asceticism and that of Christian monasticism, but the consensus of opinion among modern scholars is that they were a radical offshoot of pre-Christian Judaism. The supposition that the Therapeutae were a branch of the Essenes is contested by Harnack. While these two ascetic sects resembled each other in many instances and especially in discipline, the Therapeutae regulations were more severe.

To the modern reader the importance of the Therapeutae, as of the Essenes, lies in the evidence they afford of the existence of the monastic system long before the Christian era. We have no clue to the origin of the Therapeutae, but it is plain that they were already ancient when Philo described them. Eusebius was so much struck by the likeness of the Therapeutae to the Christian monks of his own day as to claim that they were Christians converted by the preaching of St. Mark. He goes so far as to say that "the writings of ancient men, who were the founders of the sect" referred to by Philo, may very well have been the Gospels and Epistles (which were not yet written). Eusebius having gone wrong on this point, others of the Fathers followed suit, so that Philo is reckoned by Jerome among the ecclesiastical writers of the Christians.

THERAPEUTICS, the name given to that branch of medicine which deals with the means employed to prevent or cure disease if possible, or to control and lessen its evil results when a cure is impossible.

Treatment may be symptomatic or radical, empirical or rational. Obviously the ideal is a radical treatment based on reasoned knowledge of the disease and of the means employed to combat it. Such a form of therapeutics is represented by the antitoxin treatment of diphtheria But in the case of many diseases and drugs knowledge is still so imperfect that symptomatic and empirical treatment is all that can be employed at the present time. Of this form of therapeutics the use of colchicum in gout is an example. In the case of drugs the purpose to which each is usually put is contained in the article under that special heading (*e.g.,* DIGITALIS, OPIUM, QUININE, etc.); here other and more recent therapeutic methods are considered.

Prevention.—Prevention, the ideal aim of medicine, has greatly advanced in its practical application. In Great Britain this has been fostered by the establishment of a Ministry of Health in 1919 which has greatly expanded the scope of work carried on by the Local Government Board, and also by the activities of the Medical Research Council founded in 1913 as part of the National Insurance Scheme. Preventive medicine includes, in addition to improvement of environmental conditions, prophylactic treatment in the very early stages of disease, such as can be provided in antenatal, school, dental and venereal clinics and so comes within the heading of therapeutics.

A notable example of prophylactic treatment is the prevention of goitre (*see* GOITRE); this is an endemic or local disease, probably depending, as Lieut.-Colonel R. McCarrison in India showed, on contamination of the water supply with micro-organisms; it is extremely prevalent in Switzerland and in North America both in men and lower animals in the neighbourhood of the Great Lakes, and has been found to be associated with a diminished content of iodine, which has a well-marked antiseptic action, in the thyroid gland. By the periodical administration of iodine to children in districts where the condition is prevalent it has been most suc-

cessfully prevented.

Deficiency Diseases.—Another aspect of the same question is presented by the group of "the deficiency diseases" or the avitaminoses, which depend on the absence from the food of the vitamins or "accessory food factors." As constituents of food these vitamins (*q.v.*), of which there are several, are remarkable for the contrast between the extremely minute amounts present and the striking changes resulting from their absence. (*See* BERI-BERI, SCURVY, RICKETS, PELLAGRA.)

Tropical Diseases.—The prevention of tropical disease, originated in Great Britain under Sir Ronald Ross's direction with the destruction of the mosquito, the carrier of the malarial parasite (*see* TROPICAL MEDICINE), has been much expanded by the Rockefeller Foundation, which has instituted many campaigns against diseases, such as malaria, yellow fever and especially a world-wide attack on ankylostomiasis (*see* HOOKWORM; MALARIA; YELLOW FEVER). Yellow fever, which formerly took such a terrible toll of life, has now been almost entirely eradicated from South America by destruction of mosquitoes, the carriers of the infection.

Inoculation.—The World War proved the enormous value of prophylactic or protective inoculations against certain diseases on the same lines as Edward Jenner's vaccination against smallpox (*q v.*). Just before the South African campaign Sir Almroth Wright started the method of protection against typhoid fever (*see* IMMUNITY) by injection with a vaccine composed of killed cultures of the *Bacillus typhosus;* this inoculation sets up changes in the body which render the individual immune for a time, probably about four years, to this form of infection, in the same way as an attack of the disease After the South African campaign cases were observed resembling typhoid fever but due to different though allied bacilli, and two additional forms, paratyphoid A and paratyphoid B, of fever became recognized, the three diseases being collectively described as enteric fever (*q.v*). In order to protect against infection of these three forms of fever, it is necessary to inoculate the individual with the three vaccines, and soon after the outbreak of the World War paratyphoid fever attacked the troops in Flanders and did not spare those inoculated against typhoid fever only; the three vaccines, known collectively as T A B, were then given, and the wonderful freedom of the army from enteric fever, which in past wars has killed as many as bullets, was a triumph for preventive medicine. In like manner men who were wounded and so likely to be infected with *Bacillus tetani* (*see* TETANUS), were at once injected with antitetanic serum and so protected from tetanus or lockjaw

Dysentery (*q v*) is another war disease, and there were many cases among the troops at Gallipoli and elsewhere in the East There is more than one kind of dysentery One of them, amoebic dysentery, is prone to be followed by liver abscess, the amoeba passing to the liver Before the War it was found that emetine, an alkaloid of ipecacuanha which had been long known as an empirical remedy for dysentery, was extremely efficient in curing this form of dysentery and also the hepatitis or inflammation of the liver which precedes the formation of an abscess

Psychotherapy.—As a result of the large numbers of officers and men who suffered from war strain and its effects, often called shell-shock, during and after the War, the psychotherapy of these nervous disorders has greatly developed (*see* PSYCHOTHERAPY).

Endocrine Therapy.—When any of the endocrine glands, the thyroid, adrenals, pituitary, which pour an internal secretion into the blood and keep the body in health, are diseased or fail to do their work properly, signs of disorder or disease result. The secretion may be suppressed or diminished, excessive or altered in character (*see* ENDOCRINOLOGY). When the secretion is diminished an attempt to provide it can be made, and in the case of thyroid, which when inadequate produces myxoedema, or in early life cretinism, brilliant results have long been obtained by this substitution therapy of giving the thyroid gland or an extract of it by the mouth In 1914 E C Kendall of the Mayo Clinic, Rochester, Minnesota, obtained in a pure form the active principle—thyroxin —which is extremely effective. The parathyroid glands, small bodies close to the thyroid gland in the neck, manufacture an internal secretion which passes into the blood and exerts an action apparently opposed to that of the thyroid. Whereas the thyroid is concerned with the control of iodine in the body, the parathyroids deal in a similar manner with calcium salts. Deficiency in the action of the parathyroids appears to lead to a diminished quantity of calcium salts in the body and to an irritable state of the nervous system, and is thought to be responsible in children for the contracture of the hands and feet known as tetany, though on this question there is considerable discussion. Recently the extract of the parathyroid glands has been given in a number of diseases of a chronic infective nature, especially in sprue (*see* SPRUE), a tropical disease characterized by diarrhoea, want of digestion of food so that the patient wastes as if from starvation.

Organotherapy.—An outstanding advance in organotherapy is the insulin treatment of diabetes mellitus (*see* DIABETES). In this disease the patient, who is unable to utilize sugar and starches, passes sugar in the urine, wastes and may eventually die in coma. The pancreas, or sweetbread, is a gland concerned with the digestion of food, including starches, in the alimentary canal, and at the same time that it provides this external secretion pours an internal secretion into the blood which enables the body to make use of sugar. This internal secretion is manufactured by structures in the pancreas known as the islands of Langerhans, and the extract from them is called insulin. After many trials the technical difficulties in obtaining a satisfactory insulin (*see* INSULIN) were surmounted in 1922 by F. C Banting and C. H. Best of Toronto, and a remedy was thus made available, which though it does not cure diabetes, any more than the thyroid extract cures myxoedema, yet for some hours makes the previous diabetic practically a normal person as regards the utilization of starch and sugar. The hypodermic administration of insulin must be repeated at least once daily, but this treatment keeps the disease in abeyance and has thus prolonged and saved innumerable lives. In diabetes insipidus, a comparatively rare disease, in which large quantities of urine free from sugar are passed, relief for some hours is similarly obtained by hypodermic injection of extract of the posterior lobe of the pituitary gland The success of thyroid and insulin treatment has stimulated research and trial in the case of other glands and numerous commercial preparations have been placed on the market; but the claims sometimes made for various forms of organotherapy have yet to be confirmed The most recent is the treatment of pernicious anaemia by feeding with liver This method was introduced by Minot of the Rockefeller Institute and the success he claims for it has been confirmed in England

Chemiotherapy.—Chemiotherapy, or the use of a drug which has a selective affinity for a germ and leads to its destruction without damaging the tissues of the body, was the conception of Paul Ehrlich of Frankfort-on-Main who in 1910 discovered the specific remedy "606" or salvarsan which rapidly leads to the destruction of the *Spirochaeta pallida* (*see* VENEREAL DISEASES), the protozoan responsible for syphilis It now appears that the action is not independent of the activities of the patients' bodies and that the germ is not poisoned and killed off solely by the drug, which indeed may damage the tissues of the patient very severely and even cause death, so that the ideal of chemiotherapy has not been realised. Remedies of this class are, like quinine in malaria, specific, lead to a complete cure, and are therefore of the greatest importance in opening a new vista in medicine. Since its introduction salvarsan and its modification neo-salvarsan "914" and allied organic preparations of arsenic have been increasingly used in the numerous results of syphilis with great success; but this treatment has its limitations, for when the parasite of syphilis gets inside the central nervous system and causes locomotor ataxia and general paralysis of the insane the drug cannot follow the spirochaete and the disease is little if at all influenced Recently it has been found that inoculation with the malarial organism and an attack of the disease benefits patients with general paralysis, but how far this is a permanent cure remains to be proved (*see* MALARIA). Trypanosomes, animal (or protozoan) parasites closely akin to spirochaetes are responsible for diseases, such as trypanosomiasis and African sleeping sickness (to be distinguished from quite a different disease epidemic encephalitis [*see* ENCEPHALITIS LETHARGICA] popularly called sleepy sickness) which are also curable by

the organic arsenical compounds atoxyl and arsacetin. Tartar-emetic, a salt of antimony, acts like arsenic on trypanosomes and in addition effects a cure in bilharziasis (*see* BILHARZIASIS) (a disease due to flukes), filarial disease and kala-azar, three tropical infections (*see* KALA-AZAR; PHARMACOLOGY).

Serum Therapy.—Just as in enteric fever, so in cerebro-spinal ("spotted") fever and pneumonia (*see* CEREBRO-SPINAL FEVER) bacteriology has shown the existence of several strains or types of the causal micro-organism; these though morphologically indistinguishable are so biologically different that each is most efficiently treated by an antitoxic serum, obtained from an animal injected with, and so immunised to, that particular type. Before the recognition of these types antitoxic serums were employed, but they might or might not correspond to the exact strain of the micro-organism present in an individual case In 1913 Douchez and Gillespie, working at the Rockefeller Institute, New York, isolated four types of pneumococci, the micro-organism causing acute pneumonia; but it is only the antitoxic serum corresponding to pneumococcus type I that is curative.

During the World War, especially in 1915, epidemic cerebro-spinal meningitis or cerebro-spinal ("spotted") fever became prevalent among the fighting forces, especially in young recruits It is due to the *Meningococcus intracellularis* (*see* SPINAL MENINGITIS; SERUM THERAPY), and in order effectively to neutralise its effects Simon Flexner of the Rockefeller Institute prepared an antitoxic serum from animals immunised from 40 different strains (multivalent). This serum is injected by lumbar puncture into the (subdural) space around the spinal cord, so that it can come into direct contact with the meningococci which chiefly select the central nervous system The prevalence of the disease stimulated research and strains of meningococci were isolated; Mervyn Gordon, working for the Medical Research Committee (now Council), isolated four types of meningococci and prepared four corresponding mono-type sera; when a case was bacteriologically proved to be due to infection with one of these strains, the corresponding serum was given, while waiting for the bacteriological decision as to the responsible type, a mixture of type I. and type II serum was given, as 80 to 85% of the cases were due to these strains

Tuberculosis.—The search for a specific remedy for tuberculosis, such as a new form of tuberculin, an antitoxic serum or a metallic preparation analogous to salvarsan or tartrate of antimony in protozoan diseases, has continued, but no finality has been reached (*see* TUBERCULOSIS). Spahlinger's treatment by vaccines and serums has received intermittent attention, mainly in the lay press, Dreyer in 1923, by removing the fatty material from tubercle bacilli, obtained a vaccine, called diaphyte, which has been tried on human beings, and from experiments on animals was at first thought to have an increased effect, as compared with other vaccines; later reports have not been favourable, but both experimentally and clinically it may still be premature to decide about its ultimate value Recently sanocrysine (a gold compound) has been introduced by Möllgaard of Copenhagen and is still on trial; it is a powerful remedy which kills the tubercle bacilli and, by liberating their poisons, may produce severe constitutional reactions; Knud Faber, from his clinical experience, points out that to avoid these dangerous results, the doses should be small.

In pulmonary tuberculosis a great factor in obtaining arrest and cure of the disease is rest, and in order to immobilize the lung the production of artificial pneumothorax (*q v.*) is now widely practised. Air is introduced into the pleural cavity on the side of the affected lung which then collapses and comes to rest, all the work of respiration being carried on by the other lung. This procedure has given very good results in selected cases. Treatment in sanatoria is of great value in arresting the progress of pulmonary disease and in teaching the patient the laws of health that he must follow, but it is now becoming recognized that there is urgent need for a more prolonged protection from the strain of ordinary life in the environment of cities, and that tuberculous colonies in the country are required for this purpose, such as Papworth near Cambridge and Preston Hall near Maidstone.

The treatment of leprosy (*see* LEPROSY) by intravenous and intramuscular injections of soluble products of chaulmoogra, hydnocarpus, soya bean and cod-liver oils, as advocated by Sir Leonard Rogers, has been shown by reports from leper asylums in various parts of the world to have had beneficial effects and to have reduced the death-rate in a remarkable manner. Although there are very few lepers in Great Britain, there are 300,000 in the British Empire, and at a conservative estimate 1,700,000 in the world, so that any efficient remedy is obviously important.

Protein Therapy.—By a turn of the wheel the strictly scientific employment of vaccines composed of the micro-organisms thought to be responsible for the morbid conditions has led by an empirical process to non-specific protein therapy. It was found, sometimes accidentally, not only that the administration of a vaccine specific for one form of infection benefits a morbid condition due to another infection, but that intravenous injection of foreign protein, such as peptone and milk may when they set up a reaction, namely fever, shivering and illness ("protein shock therapy"), produce a beneficial effect, just as one disease sometimes cures another. This protein shock therapy has been employed particularly in asthma and in chronic rheumatoid arthritis.

After an attack of many infective diseases there develops an immunity so that a second attack is rare; the reverse of immunity is an exaggerated susceptibility or hypersensitiveness (*see* ANAPHYLAXIS); this is what is meant by idiosyncrasies and the proverb "What is one man's meat is another man's poison." This is seen in various diseases, such as recurrent colds and asthma. A method of cure is to desensitize the subject of one of these toxic idiopathies by the administration, usually by hypodermic injection, of the substance, a bacterial or other protein, to which the individual is hypersensitive Thus a patient subject to hay fever is injected with the pollen of the plant which excites an attack; or a patient with bronchitis and asthmatic seizures is injected with an emulsion of dead bacilli (vaccine) obtained from the expectoration

In many cases of disease and ill-health the cause is a "septic focus" or a local collection of micro-organisms, for example, in the teeth (*see* DENTISTRY), tonsils, appendix, gall bladder and intestines, which poison the body and may produce chronic painful conditions, such as chronic arthritis, sciatica, lumbago, fibrositis The removal of such foci is therefore the important and indeed the first step in treatment; after that vaccines made from the predominant micro-organism present in the focus, and spa treatment may complete the cure.

Anaemia.—The form of anaemia (*q v.*) called pernicious or Addisonian after its describer Thomas Addison of Guy's Hospital (*see* ANAEMIA) is apparently the result of chronic infection of the stomach and alimentary canal, which in its turn may be due to a septic focus, but the observations of Arthur F Hurst, also of Guy's Hospital, indicate that an important factor is absence of the hydrochloric acid in the gastric juice. It has, therefore, been treated by supplying the absent hydrochloric acid by its medicinal administration by the mouth, with a success which is due to investigation of the chemistry of the stomach. The manner in which liver feeding acts in pernicious anaemia (*vide supra*) is unknown

In pernicious anaemia, as in anaemia due to haemorrhage, transfusion of blood (*see* BLOOD TRANSFUSION) has been carried out, after the blood of the donor has been compared with that of the patient to see that they are compatible and after measures have been taken to avoid transmitting diseases, such as influenza, malaria and syphilis from the donor. Transfusion of blood is a very old method of treatment and was performed as long ago as 1667, but it is only recently that the tests for the compatibility of the blood based on the existence of four blood groups in man have rendered the procedure less dangerous Transfusion of blood with these precautions was employed on a large scale in the War for haemorrhages and severe shock, as from gunshot and shell wounds, and has also been used in conditions popularly called blood poisoning. A recent development of blood transfusion is to immunize by means of vaccines, made from the micro-organism infecting the patient, the blood of the donor, and then to transfuse his blood into the patient.

Radiotherapy.—X-rays, though mainly employed for diagnosis, have from their power of destroying the tissue cells, many

therapeutic uses. Thus enlarged glands and the spleen in various diseases of the blood, and especially in lymphadenoma, are much reduced by X-ray exposure. The recent Erlangen treatment of internal cancer by intensive X-rays has the grave disadvantage of making some patients extremely ill (*see* RADIOTHERAPY) Radium bromide, the rays of which are much the same, has been much used in the treatment of inoperable carcinoma and in quite superficial growths of the skin, especially rodent ulcer on the face, which, though classed as malignant, is much less virulent. In cancer of the neck of the womb radium has proved of unquestionable value; from a combination of operation and radium good results have been obtained in cancer of the breast; in malignant growths of the tongue, mouth and throat its successful use is probably dependent upon technique

The important advance in the diagnosis of disorders of the heart and the mechanism of its beat have been followed by a more accurate knowledge of how to give digitalis and by the employment of quinidine in the disorders known as auricular fibrillation and paroxysmal tachycardia. Numerous researches have been undertaken with the view of devising reliable tests for the functional activity of the liver, and it is clear that sugar is the food which most readily protects and repairs the damaged liver cells

Heliotherapy.—Recent years have shown an increasing tendency to utilize to the full the *vis medicatrix naturae* in open air treatment, improved ventilation, heliotherapy which has indeed been imitated by the use of ultra-violet rays (*see* HELIOTHERAPY), baths and waters, and exercises. The prophylactic measures based on experience and empirical use have been elaborated by the teaching of scientific research and as a result physiotherapy or physical therapeutics, which includes massage and the various forms of electrical treatment, has considerably advanced in knowledge and application Medical hydrology has been studied and taught on these rather than on purely empirical lines, and it may be noted that spas did excellent work during and after the War for invalided soldiers Hand in hand with open air treatment and heliotherapy has come less surgical activity in the way of operating in tuberculous disease of bones and joints (H R)

THERESA, ST. (1515–1582), or Teresa de Cepeda, Spanish nun, was born at Avila, in Old Castile, on March 28, 1515, and was educated in an Augustinian convent in the town At the age of eighteen she entered the Carmelite convent of the Incarnation In 1554, when she was nearly forty, her conversion took place, and the second part of her life began The death of her father roused her to serious reflection, and one day, as she entered the oratory, she was struck by the image of the wounded Christ, placed there for an approaching festival. She fell in tears at the feet of the figure, and felt every worldly emotion die within her. The shock threw her into a trance, and these trances, accompanied by visions, recurred frequently in the subsequent part of her life The visions grew more and more vivid The cross of her rosary was snatched from her hand one day, and when returned it was made of jewels more brilliant than diamonds, visible, however, to her alone. She had often an acute pain in her side, and fancied that an angel came to her with a lance tipped with fire, which he struck into her heart. Aug 27 is kept sacred in Spain to this mystery.

Foundation of the Descalzos.—Meanwhile, the spread of the Reformation exercised the minds of pious Catholics. Teresa sought the cause of the catastrophe in the relaxation of discipline within the religious orders. She determined to found a house in which all the original rules of the Carmelite order would be observed. In spite of great opposition from the authorities of the order, and in particular from the prioress and sisters of the Incarnation, she persevered with her scheme, and secured papal approval. On Aug. 24, 1562, mass was said in the little chapel of the house prepared for her at Avila and the new order constituted. It was to be an order of Descalzos or Barefoots, in opposition to the relaxed parent body, the Calzados. The sisters were to wear sandals of rope; they were to sleep on straw, to eat no meat, to be strictly confined to the cloister, and to live on alms without regular endowment. Teresa encountered great opposition, but after six months a fresh bull arrived from Pius V., and the provincial of her order now gave her leave to remove and take charge of her sisterhood The number of thirteen, to which on grounds of discipline she had limited the foundation, was soon filled up, and Teresa spent here her five happiest years.

Her visions continued, and, by command of her ecclesiastical superiors, she wrote her autobiography containing an account of these experiences but she based no claim to holiness upon them.

The general of the order visited her at Avila, and gave her powers to found other houses of Descalzos, for men as well as women. The last fifteen years of her life were spent mainly in hard journeys with this end and in the continually growing labour of organization. Convents were founded at Medina, Malaga, Valladolid, Toledo, Segovia and Salamanca, and two at Alva under the patronage of the famous duke. Then she had three years of rest, as prioress of her old convent of the Incarnation She next went to Seville to found a house, thus overstepping for the first time the boundaries of the Castiles, to which her authorization limited her. The latent hostility of the old order was aroused; the general ordered the immediate suppression of the house at Seville, and procured a bull from Gregory XIII prohibiting the further extension of the reformed houses (1575) But the movement against her came from Italy, and was resented by Philip and the Spanish authorities as undue interference; and after a fierce struggle, during which Teresa was two years under arrest at Toledo, the Carmelites were divided into two bodies in 1580, and the Descalzos obtained the right to elect their own provincial-generals (*See* CARMELITES) The few remaining years of Teresa's life were spent in the old way, organizing the order she had founded, and travelling about to open new convents Sixteen convents and 14 monasteries were founded by her efforts; she wrote a history of her foundations, which forms a supplement to her autobiography Her last journey of inspection was cut short at Alva, where she died on Sept 29, 1582

Canonization.—A violet odour and a fragrant oil were said to distil from her tomb; and when it was opened nine months afterwards the flesh was found uncorrupted Her relics were found to work miracles She was buried at Avila, but her remains were eventually restored to Alva Teresa was canonized by Gregory XV. in 1622. The honour was doubtless largely due to her asceticism and mystic visions She called herself Teresa de Jesus, to signify the closeness of her relation to the heavenly Bridegroom, who directed all her actions. Though she deprecated excess of ascetic severity in others, she scourged herself habitually, and wore a peculiarly painful hair-cloth. But her life shows her to have been, besides, a woman of strong practicality and good sense, full of natural shrewdness, and with unusual powers of organization. "You deceived me in saying she was a woman," writes one of her confessors; "she is a bearded man." She was brave in the face of difficulties and dangers, pure in her motives, and her utterances, some of which have been quoted, have the true ethical ring about them. Her mss. were collected by Philip II. and placed in a rich case in the Escorial, the key of which the king carried about with him. Besides her autobiography and the history of her foundations, her works (all written in Spanish) contain a great number of letters and various treatises of mystical religion, the chief of which are *The Way of Perfection* and *The Castle of the Soul*. Both describe the progress of the soul towards perfect union with God.

Her works, edited by two Dominicans, were published in 1587, and have since appeared in various editions. They were translated into Italian, French (4 vols., 1840–46) and Latin, and an English translation of the *Life* and works (except the letters) by A. Woodhead appeared in 1669. Other translations are: J. Dalton, *Life* (1851), *The Way of Perfection* and *Letters* (1902); D. Lewis, *Life* (1870), *Foundations* (1871); A. R. Waller reprinted Woodhead's translation of *The Way of Perfection* (1901); B. Zimmerman, *Minor Works* (1913); *The Way of Perfection* (1916); *The Interior Castle* (3rd ed. 1921). A translation of the *Letters* with introduction by Cardinal Gasquet appeared 1919–24 (4 vols.).

THEREZINA, a city of Brazil, capital of the State of Piauhy, on the right bank of the Parnahyba river, about 220 m. from its mouth. The population for the commune or municipio, (1920) was 57,500. It is prettily situated on an open plain and is laid out regularly with broad straight streets with seven large squares. The town is characteristically Portuguese in appearance, its buildings being one or two stories in height, plastered and frequently coloured outside, with large rooms, thick walls, and tile roofs to ensure coolness. Its manufacturing industries include cotton-mills, sugar refineries, a foundry, and soap-works. A steamboat service, with small boats, maintains regular communication with Parnahyba, near the mouth of the river, besides which there are a number of independent freight-carrying boats. A railway connects Senado Furtado, across the river Parnahyba, with the port of São Luiz on the coast of Maranhão. Therezina was founded in 1852, its site being originally called Chapada de Corisco, and was named after the Empress Thereza Christina.

THERM. A name originally employed in elementary textbooks for any thermal unit, but now generally restricted to the statutory unit of heat adopted for the sale of lighting gas in terms of its calorific value. For this purpose the therm has been defined as being equal to 100,000 British Thermal Units (B.T.U.) the unit of heat most commonly employed for measuring the calorific value of gas or other fuels throughout the British empire and the United States of America (*See* GAS LIGHTING.)

THERMAE, in classic architecture, originally warm baths, but then used of any large bathing establishment. (*See* BATHS.)

THERMIDOR, the name given during the French Revolution to the eleventh month of the year in the Republican calendar. The name Revolution of Thermidor is often given to the events of 9 Thermidor year II (July 27 1794), which resulted in the fall of Robespierre and the collapse of the Terror The name Thermidorian (*Thermidorien*) was given to the authors of this revolution and to the supporters of the reactionary movement of which it was the signal.

THERMIONICS. Thermionics is the branch of science which deals with the influence of heat on matter in generating atomic or sub-atomic electrically charged particles (ions or electrons) and with the electrical properties of the assemblages so produced Effects of this general character have been familiar to physicists for about two hundred years but the subject attracted little attention until about the beginning of the present century when J J. Thomson discovered that the carriers of these discharges at very low gas pressures were electrons and O W Richardson discovered the fundamental law connecting the phenomena with temperature In recent years interest in the subject has extended to a still wider field owing to the great importance of its electrotechnical applications, particularly to the art of electrical communication (*See* art. THERMIONIC VALVE.) In the treatment which follows, attention will be confined mainly to the emission of electrons by solids owing to the practical and theoretical interest of this aspect of the subject.

If a solid body, for example a wire, is heated in a vacuous enclosure it is found in general to emit both positively and negatively electrified particles; as may be ascertained by having a neighbouring insulated electrode in the enclosure and connecting it outside through a battery of suitable polarity and a galvanometer or other detector of electric current If the wire is of a refractory material such as tungsten or platinum and the heating is continued the positive emission, which is caused by electropositive contaminants such as potassium, dies away, so that ultimately in a highly evacuated enclosure the emission consists solely of electrons, that is to say sub-atomic negatively charged particles. In this way it comes about that a heated body admits of the escape of negative electricity from its surface, but not of positive. Thus an evacuated enclosure containing a hot and a cold conductor only allows the passage of electricity in one direction, the negative electricity passing from the hot to the cold body, and so functions as an electrical valve. This emission varies very rapidly with the temperature in a manner which will now be investigated. The electron currents from the surfaces of bodies obtained in this way at high temperatures may be very considerable.

This emission of electrons from hot bodies is a special kind of evaporation It differs from the evaporation of a solid chiefly in the fact that the particles in the gaseous phase are electrically charged. Thus a hot body in an evacuated enclosure will be surrounded by an electron gas which will be capable of exerting a pressure and in fact will have the same dynamical properties as other gases having the same temperature and molecular concentration. The reason why the electrons do not all prefer to leave the solid for the enclosure is that they have to do a certain amount of work in passing through its surface This electron atmosphere will be capable of being in equilibrium with all the bodies present in the enclosure at any fixed temperature and in this condition each body will emit in a given time as many electrons as it receives.

If we suppose a single hot body to be contained in such an enclosure maintained at the absolute temperature T°K and if the enclosure is provided with a movable piston we can obtain useful work from the pressure p exerted by the electron atmosphere on the piston. If there are n electrons in unit volume, if v is the volume of the enclosure and ϕ is the change of energy when one electron passes from the hot body to the surrounding space, the increment dS in the entropy of the system due to an infinitesimal displacement of the piston is

$$dS = \frac{1}{T}\{d(nv\phi)+pdv\} \qquad (1)$$

The second law of thermo-dynamics requires that dS should be a complete differential in v and T from which we deduce

$$T\frac{\partial p}{\partial T} = p + n\phi \qquad (2)$$

In very small concentrations such as we are now dealing with the pressure of the electron atmosphere must be governed by the gas law

$$p = nkT \qquad (3)$$

where k is Boltzmann's constant By integrating (2) after substituting from (3) we get

$$n = A_0 e \int^T \frac{\phi}{kT^2}\,dT \qquad (4)$$

where A_0 is independent of the temperature. If we neglect small quantities comparable with the specific heat of electricity (Thomson coefficient) it can be shown that

$$\phi = \phi_0 + \tfrac{3}{2}kT \qquad (5)$$

where ϕ_0 is the value of ϕ at O°K Hence

$$n = A_1 T^{3/2}\,\epsilon^{-\phi_0/kT} \qquad (6)$$

The constant A_1 is, subject to some reservations which it would take too long to discuss in this article, a universal constant, the only material constant entering into the formula being ϕ_0 Equation (6) gives the concentration of the electrons in the equilibrium atmosphere. This is not readily accessible to experiment but it is related in a very simple way to the maximum emission current i_0 which is easily measured The relation is

$$i_0 = ne\sqrt{\frac{kT}{2\pi m}} \qquad (7)$$

where e is the charge and m the mass of the electron. By combining (6) and (7)

$$i_0 = AT^2\epsilon^{-\phi_0/kT} \qquad (8)$$

Subject to the reservations referred to above and to the further assumption that different substances reflect electrons to the same extent, the constant A should have the same value for all substances. Its absolute value can be determined by introducing the quantum theory. It is

$$A = \frac{2\pi k^2 me}{h^3}\alpha \qquad (9)$$

where h is Planck's constant and α is the proportion of an incident beam of electron gas reflected at the surface

The most usual device for testing the implications of equation (8) is to use an electrically heated wire placed on the axis of a surrounding cylinder, both these elements being suitably mounted in an evacuated container of glass or quartz. If a steady potential difference is maintained between the hot wire and the cylinder by means of an external battery, the current across the gap can be measured by a galvanometer placed in series with the battery. If the wire is held at a high positive potential no current will flow, but with a small positive potential it is found that a small current flows in a direction contrary to the applied potential difference. The reason for this is that the large potential differences are high enough to stop all the emitted electrons from reaching the opposite electrode The electrons, however, are not emitted with zero velocity in general but some of them have sufficient initial kinetic energy to carry them to the opposite electrode against a small opposing electric field. If the wire is charged negatively, then the number of electrons which are carried across the gap increases as the accelerating field is increased This increase does not go on without limit, but a stage is soon reached when the electron current becomes independent of any further increase in the applied potential differences. The reason for this is that the field is now so strong that it carries to the cold electrode all the electrons which are emitted from the hot wire. This limiting value of the current is known as the saturation current and when reduced to unit area it is the quantity to which the symbol i_0 in equation (8) applies. The chief reason why this current rises to the saturation value gradually and that any accelerating potential, however small, is insufficient to guide the electrons across the gap is the effect of the self repulsion of the electrons This effect is more marked the higher the temperature, that is to say the greater the maximum current to be dealt with.

The validity of an equation of the form

$$i_0 = AT^{\alpha}\epsilon^{-b/T} \qquad (8\ 1)$$

with A, α and b constants and α comparable with unity is well established experimentally In the case of tungsten it has been shown to be valid over a range of variation by 10^{12} in the current i_0 and a corresponding range in the temperature An earlier theoretical formula put $\alpha = \frac{1}{2}$ and from an empirical point of view there is little to choose between $\alpha = \frac{1}{2}$ and $\alpha = 2$ on account of the insensitivity of the factor T^{α} compared with the exponential term, but the formula with $\alpha = 2$ is definitely required by theoretical considerations This brings us back to equation (8), viz : $i_0 = AT^2\epsilon^{-\phi_0/kT}$, in which form A/α should have the absolute value expressed by (9). There is no doubt that for a considerable number of metals A is comparable with

$$\frac{2\pi k^2 me}{h^2}\ (=60\ 2\ \text{amps cm}^{-1})$$

Whether such deviations as appear are due to the neglect of electron reflection ($\alpha \neq 1$) or to other refinements which have been disregarded is at present under experimental investigation There is, however, no reason to doubt that the major part of A is given by equation (9).

The remaining constant ϕ_0 in equation (8), which is the only constant in the equation involving the specific properties of the material concerned, is directly related to other important physical properties of the substance If we consider an enclosure containing two different substances in contact and imagine an electron taken along a closed path passing through the area of contact and also outside both substances the law of conservation of energy requires that

$$\phi_1 - \phi_2 = eV - eP \qquad (10)$$

where ϕ_1 and ϕ_2 are the values of ϕ (the quantity in equations (4) and (5) above) for each substance, V is the contact potential difference between them, P is the Peltier electromotive force at the junction and e the electronic charge. In general P is small compared with V in (10), so that if we neglect the thermoelectric terms as small compared with the others it follows from (5) that the contact potential difference (Volta effect) between two substances is equal to the difference in the values of ϕ_0 appropriate to them. Another relation satisfied by the contact potential V is

$$V = \frac{kT}{e}\log\frac{i_2}{i_1} \qquad (11)$$

i_2 and i_1 being the saturation current densities from the two substances at temperature T The quantity ϕ_0 is also equal to $h\nu_0$ where ν_0 is least frequency of light which is able to eject electrons from the material under consideration. For all metals ϕ_0 is of the order of magnitude 4 in equivalent volts the values ranging from about 2 for the most electropositive to about 6 for the most electronegative metals

When a current of electrons is drawn away from the surface of a hot body, each electron has to do an amount of work ϕ in escaping This involves a cooling effect of equivalent amount at the surface of the wire There is also an equal heating effect at the surface when a stream of electrons flows into a body. These effects are precisely analogous to the cooling and heating effects caused by the more familiar evaporation and condensation of vapours Their magnitudes have been measured and are in agreement with the values of ϕ got from the variation of the emission with temperature

It has been mentioned that with small retarding fields there is an electron current from hot bodies, so that the current flows in a direction opposite to that of the applied electromotive force. This is due to the fact that the electrons are emitted with definite initial velocities. By measuring the currents which will flow against various retarding potentials the number which have a velocity exceeding any assigned value can be ascertained In this way it has been found that the emitted electrons have the same distribution of velocity as would have the molecules of a gas of the same molecular weight at the same temperature in accordance with Maxwell's Law To be precise, out of any number N emitted, the number with velocity components between u and $u+du$ perpendicular to the surface is

$$N u du = N\frac{m}{kT}\epsilon^{-(mu^2/kT)}du \qquad (12)$$

and the number with velocity components between v and $v+dv$ parallel to the surface is

$$N v dv = N\left(\frac{m}{2\pi kT}\right)^{\frac{1}{2}}\epsilon^{-(mv^2/kT)}dv \qquad (13)$$

For practical purposes a thermionic source of electrons should be very refractory and preferably have a low value of ϕ. The refractoriness is required to ensure durability and to withstand the somewhat drastic preliminary heating treatment which is required to establish the necessary degree of vacuum. The best material on the score of refractoriness is tungsten, but it has a rather high ϕ (about 4 5 volts) This can be reduced by mixing a small quantity of thoria with the tungsten during manufacture which by an appropriate technical treatment produces a layer of thorium over the tungsten surface. Similar effects are got by coating suitable metals with mixtures of the oxides of the alkaline earths or with the products of the decomposition of barium azide. In these cases also it is believed that the effects are due to a layer of the alkaline earth metal which develops on the surface of the supporting metal. It has also been found that tungsten, and especially oxidized tungsten, can be coated with layers of alkali metals such as potassium and caesium which are stable below a certain limiting temperature. These bodies admit of quantitative study and it is found that the effective work function ϕ has a minimum value when the layer of alkali metal is approximately one atom thick. There is perhaps still some uncertainty as to the values of the work function for the pure alkali metals, but it is probable that they are higher than this minimum value. This conclusion is supported by the existence of an exactly parallel displacement of the photo-electric threshold with the composition of the surfaces in which the minimum value is less than that for the pure alkali metal.

There is evidence in some cases of the emission of electrons from a body in which more than one work function is involved

It is, however, not established that such an effect may occur at a single surface of a crystal of a pure element.

The emission of electrons from metals is in general very sensitive to the action of gaseous contaminants. These effects, which are complicated and only partially understood, are mainly indirect and caused by the modification of the surface arising from the interaction with the gaseous atmosphere. For any given atmosphere there is usually a fairly stable emission condition characterized by fairly definite values of A and b in equation (8·1). These values may, however, differ enormously from the standard values for the pure metal, but they are characterized by the remarkable fact that, no matter by what agencies the changes are caused, the new values always satisfy approximately a relation of the form $b = \text{const} \times \log A + \text{constant} \ldots\ldots (14)$ A similar relation has been observed in connection with the emission of positive ions by hot metals in gases No observable effects on the electronic emission from hot bodies are caused by the inert gases and vapours such as helium, argon or mercury.

It is required by thermodynamics that the total photoelectric emission of electrons from any substance in equilibrium at temperature T arising from the equilibrium (black body) radiation imprisoned within it should satisfy an equation of the same form as equation (8) and with an identical exponential factor This makes it possible to regard the thermionic electron emission from a substance as an integrated photoelectric effect of its temperature radiation It appears, however, that the absolute value of the emission calculated from optical and photoelectric data is less than one millionth part of the thermionic emission observed at convenient temperatures Consequently this idea has not made much progress but it is not certain that it is wrong

When wires of fresh metal are heated it is found that there is a temporary emission of positive ions which usually comes off at a lower temperature than the negative electron emission Direct measurement has shown that these ions are positively charged atoms of the alkali metals This emission generally decays roughly as an exponential function of the time at constant temperature, but the decay may sometimes be preceded by an initial rise Similar effects from involatile salts, such as aluminium phosphate, are due mainly to alkaline contaminants Recently very powerful and steady sources of positive ions have been got by coating metals with an admixture of an alkali salt, and an involatile body such as iron oxide.

If a wire has been heated in a vacuum long enough for the initial positive emission to disappear and gas is admitted at a low pressure there is, in general, an emission of positive ions which is a function of the pressure of the gas It is believed that the ions in this discharge are charged atoms or molecules of the gas but this is an inference from indirect evidence and there are no direct measurements of the specific mass of the carriers. These discharges frequently exhibit slow changes with time in response to changes in the external conditions such as pressure or temperature, and there is other evidence that the formation and decomposition of surface films of adhering gas play an important part in their generation. For example, the emission in a mixture of nitrogen and oxygen such as air, is very much less than the emission in an equal amount of oxygen with the nitrogen absent. Thus the nitrogen exerts a definite inhibition on the oxygen emission. At low temperatures the emission in oxygen varies nearly as the square root of the pressure of the gas, but at high temperatures it is more nearly proportional to the pressure.

Most salts emit positive ions when heated With salts of the alkali metals or the alkaline earth metals the ions are charged atoms of the metallic constituent. These are usually singly charged but may be multiply charged if the metallic element is polyvalent. With salts in which the metallic constituent is not very electropositive the positive emission usually observed is caused by alkaline contaminants. Some salts, such as calcium iodide, emit electrons and heavy negative ions in proportions which vary with the temperature but the two emissions may, at suitable temperatures, be comparable with each other.

In all cases when the remaining conditions can be held constant the emission of positive ions from hot bodies follows the same general temperature law as that for electrons, the saturation current being given by $i = AT^{\alpha}\epsilon^{-b/T}$, A, α and b being constants and α comparable with unity

See O W. Richardson, "The Emission of Electricity from Hot Bodies" (2nd Edn., 1916). (O. W. R.)

THERMIONIC VALVE (Thermionic Tube, Audion or Radiotron) The term *thermionic valve* is applied to any form of electric discharge tube in which one or more of the electrodes is heated so as emit electricity by the process of thermionic emission More commonly the term indicates a highly-exhausted tube in which the electric current consists of negative electrons evaporated from an electrically heated wire filament and collected by a metal sheet electrode, known as the plate or anode, which surrounds the filament The maximum current which can pass through such a tube is equal to the electron current emitted by the filament or cathode. If the current passing through the tube is not as large as this emitted current, as is usually the case when the tube is in operation, the difference is made up by the return of electrons to the filament. The current reaching the anode, called the anode current, may be caused to vary by varying the potential of the anode with respect to the filament, as in a two-electrode valve or diode; or the anode potential may be fixed and the anode current controlled electrically by means of a perforated electrode or grid situated between the filament and anode, as in a three-electrode valve or triode Tubes with more than three electrodes are used, but their behaviour, in general, is very similar to that of a triode

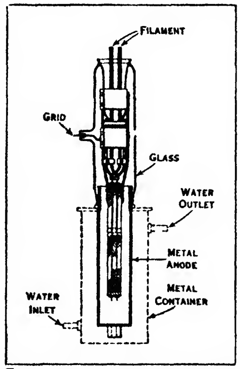

FIG 1—(A) MARCONI WATER-COOLED TRANSMITTER VALVE

Construction.—The filament is usually a wire which may be made of (a) pure tungsten, (b) thoriated tungsten, or (c) chemically-coated metal such as platinum The wire is stretched between two metal supports which act as conductors for supplying the heating current to the filament and also are connected by leads through the glass containing envelope to the external filament terminals The filament, when of pure tungsten, is maintained at a temperature of about 2400° Kelvin (2127° C). As, at this temperature, the wire is white hot, such a filament is called a *bright emitter*. Pure tungsten filaments require a greater rate of supply of heat energy to produce the same thermionic emission than do thoriated tungsten or chemically-coated filaments, and thus are not so useful for valves used in receiving sets High power valves for wireless transmitting stations, however, are operated at high anode voltages and pure tungsten filaments are chiefly used in them because of their greater ruggedness and ability to withstand accidental voltage overloads.

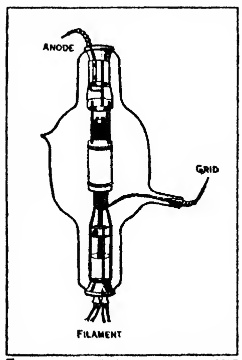

FIG. 1—(B) TRANSMITTING VALVE WITH GLASS ENVELOPE

The admixture of less than 1% of thoria (ThO_2) to a tungsten filament is found to increase very appreciably the electron evaporation at any given temperature. According to I Langmuir the thoria is turned to metallic thorium when the wire is heated and a thorium layer one molecule thick forms on the tungsten surface. It is this layer which reduces the amount of work necessary to transfer an electron across the surface and

which thus increases the electron emission A thoriated tungsten filament is usually run at 2,000° K. and since, at that temperature it is not very bright, it is called a *dull-emitter* At that temperature the electricity it emits is many times that emitted by a tungsten filament run at 2,400° K. with the same energy supply.

A typical example of a filament with a chemical coating is the oxide-coated platinum filament This is also a dull-emitter and is run at a temperature as low as 1,200° K. or even less It is usually a platinum ribbon coated with a mixture of barium and strontium oxides and carbonates The pronounced thermionic emission appears to be due to the presence of a film of metallic barium on the filament surface Another way of obtaining such a barium film is to use a filament with a copper coating on which is put barium azide (Ba_2N_6). When such a filament is heated the nitrogen is driven off leaving the barium which alloys with the copper and thus remains on the surface of the filament.

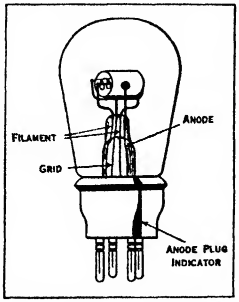

FIG 1 —(C) RECEIVING VALVE

The relation between the electron emission per sq cm. (J) of filament surface and the temperature (T) may be expressed by O W. Richardson's formula

$$J = AT^2 e^{-\frac{b_0}{T}},$$

where A and b_0 are constants for any particular substance. The values of these constants for three of the types of filament mentioned above are given in the table below In the formula J is expressed in amperes per sq cm. and T in degrees Kelvin

Filament	A (amp/cm² deg²)	b_0 (degrees Kelvin)
Tungsten	60·2	52,000
Thoriated tungsten .	3·0	30,500
Oxide-coated platinum .	$1{\cdot}07\times10^{-3}$	12,100

The ratio of the total emission from a filament to the rate of supply of energy to heat is a constant for a given temperature. For the operating temperatures used in present-day valves this ratio is about 0·003 amp per watt for tungsten, 0·050 amp per watt for thoriated tungsten and 0·130 amp per watt for oxide-coated platinum.

The other electrodes of a thermionic valve are made of nickel or molybdenum or other conductors having high melting points The anode is usually cylindrical, surrounding the grid and filament, but may consist of two parallel flat plates situated on opposite sides of the filament. The grid is usually a spiral of wire or a mesh wound on a cylinder with the filament as axis The electrode system is fixed at the centre of the containing glass, silica or metal envelope and is supported by a glass (or silica) "pinch" through which pass the connecting wires between the electrodes and the outside terminals. In a two-electrode valve there are three outside terminals, one for the plate and two for the positive and negative ends of the filament heating battery In the case of the three-electrode valve there are the same three terminals, together with an extra one for the grid.

The majority of valves are those of the high-vacuum type, so that in the process of manufacture various methods are used to rid the electrodes and glass envelope of occluded gas both before and during the process of pumping the air from the envelope. Such methods are also employed even with a tube which is subsequently made "soft" by the admission of helium.

Internal Action of a Thermionic Valve.—The performance of a thermionic valve in an electrical circuit is usually interpreted in terms of its static characteristic curves which represent the relations between the currents flowing to the collecting electrodes and the potentials of these electrodes with respect to the filament. Since the data for such curves are obtained using steady electrode potentials certain discrepancies are often found between the behaviour predicted from these curves and the actual performance of a tube when functioning with rapidly alternating electrode potentials and currents. In such cases the discrepancy can usually be traced to the effects of the electrode capacities or to the small but finite time required for the electrode currents to respond to the electrode voltage changes

(a) *The Two-Electrode Valve.*—in the case of the diode or two-electrode valve the most important characteristic is that showing the relation between the anode potential (v_a) and the anode current (i_a), the filament current being maintained constant at the normal operating value A typical diode characteristic is shown in fig. 2 and may be interpreted in terms of the internal action of the tube When the anode is at a positive potential it attracts the negative electrons and so an anode current flows. On the other hand when the anode is negatively charged it repels the electrons back into the filament as fast as they are emitted and no anode current flows From the characteristic it will be seen that as the positive potential of the anode is increased the anode current also increases until a certain maximum value is reached. A further increase of anode potential brings about no further increase of anode current and the latter is then said to have reached saturation value (i_s). The saturation current is reached when all the electrons emitted by the filament are attracted and caught by the anode The necessity for a fairly large anode potential to produce saturation current is caused by the mutual electrical repulsion between the electrons which are situated at any moment in the space between the filament and the anode This body of electrons is termed the space charge The electrons which are on their way to the anode repel those just starting from the filament, thus neutralizing to a large extent the pull which the positively charged anode exerts on the latter

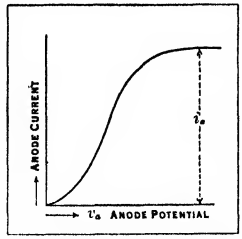

FIG 2 —CHARACTERISTIC CURVE OF TWO-ELECTRODE TUBE

The effect of the electron space charge in opposing the establishment of saturation conditions has been examined quantitatively by C D. Child and by I Langmuir The essential basis of their calculation is the assumption that the disposition and magnitude of the space charge is so adjusted that an electron at the filament surface is repelled by the electrons in front of it with a force equal and opposite to that due to the positive charge on the anode For such conditions the space charge must obviously be equal and opposite to the charge on the anode. In the case of a plane emitting surface with a parallel plane anode such assumptions lead to the Child-Langmuir formula:

$$i_a = \frac{\sqrt{2}}{9\pi}\sqrt{\frac{e}{m}}\,\frac{v_a^{3/2}}{x^2}, \qquad (1)$$

where i_a and v_a are the anode current and anode potential, e and m the charge and mass of an electron and x is the distance between the electrodes. In practical units (amp. per. cm², volts, cm) this becomes

$$i_a = 2{\cdot}33\times10^{-6}\,\frac{v_a^{3/2}}{x^2}. \qquad (2)$$

For the more usual case in which filament and anode are coaxial cylinders the formula corresponding to (1) is

$$i_a = \frac{2\sqrt{2}}{9}\sqrt{\frac{e}{m}}\,\frac{v_a^{3/2}}{r\beta^2} \qquad (3)$$

where v_a, e and m have the same significance as before, i_a is the current per unit length of cylinder, r is the radius of the anode cylinder and β is a complicated function of the ratio $\frac{r}{r_0}$ (*i.e.*, $\frac{\text{anode radius}}{\text{filament radius}}$). In practical units (am. per cm., volts, cm.) this

becomes

$$i_a = 1{\cdot}46 \times 10^{-6} \frac{v_a^{\frac{3}{2}}}{r\beta^2} \qquad (4)$$

Tables of values of β^2 for different values of $\frac{r}{r_0}$ have been given by I. Langmuir and K. B. Blodgett from which it is found that when $\frac{r}{r_0}$ is greater than 10, a condition usually met in practice, the value of β is little different from unity.

Although the Child-Langmuir formulae are sufficiently accurate for most practical purposes, the assumption of an unlimited supply of electrons from the filament makes the formulae satisfactory only for cases in which the anode current is appreciably below saturation value. Moreover the electrons, on emerging from the filament are all assumed to possess uniform velocities, either zero or finite, whereas it is known that such electrons possess velocities with a Maxwellian distribution. The effects of both finite filament emission and of the Maxwellian distribution of electron velocities have been taken into account in more elaborate treatments of the problem by P. S Epstein and T C. Fry

Two examples of the use of the two-electrode valve are its applications as a detector of wireless signals and as a rectifier of alternating current for power purposes. Both of these applications depend on the fact that when an alternating voltage is applied between anode and filament a current flows through the valve only during the half cycle when the anode is positive. The practical use of the two-electrode valve as a detector of wireless signals was first made by J A. Fleming in 1904[1], though the fact that a tube containing rarefied gas with one hot and one cold electrode showed unilateral conductivity had been previously demonstrated by Elster and Geitel in 1889 A simple wireless circuit with diode rectifier is represented in fig 3 As a result of the high frequency oscillatory potentials produced between the points A and B by the action of wireless waves on the aerial, unidirectional currents pass through and actuate the telephone or galvanometer.

For the rectification of alternating current from a power circuit, the arrangement shown in fig 4 is commonly employed

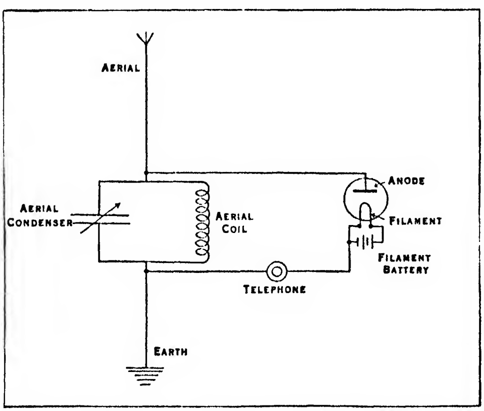

FIG 3 —SHOWING USE OF FLEMING VALVE AS WIRELESS DETECTOR

With such an arrangement the alternating supply is first transformed to a convenient voltage and then applied to two diodes, the filaments of which are connected together With this arrangement both halves of the alternating voltage cycle are used, the diodes passing current alternately. This circuit is used in many high-tension eliminators for use with broadcast receivers.

(b) *The Three-Electrode Valve.*—The introduction of a third electrode between the filament and anode was first made by Lee de Forest[2] in 1907. De Forest had previously, like Fleming, used a two-electrode tube for detecting wireless signals and had named such an instrument an audion The same name was, however, retained for the three-electrode tube of de Forest in which a zigzag wire or grid was introduced between the filament and anode. Recently the name audion has been applied to a three-electrode tube.

Because of its closer proximity to the filament, the grid of a triode permits of a more effective control of tube current than

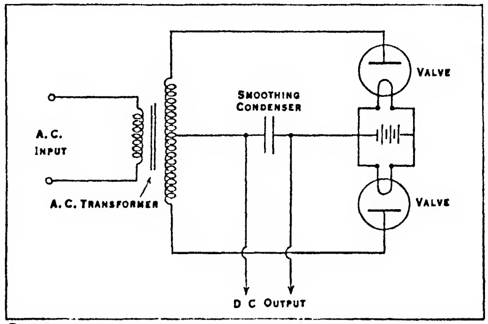

FIG. 4 —ILLUSTRATING USE OF VALVE AS RECTIFIER OF ALTERNATING CURRENT

does the anode This control is effected by way of space-charge neutralization and this is determined quantitatively in terms of the positive charges on the grid and anode For example, if the grid and anode are maintained at the same positive potential with respect to the filament the charge on the grid is greater than that on the anode Actually it is m times as large where m is the amplification factor of the tube For normal operating conditions the grid and anode potentials are not the same, but the effect is similar, for if we increase the grid potential by say one volt the increased charge it acquires is m times as large as that acquired by the anode when its potential is similarly increased.

The electron current leaving the filament which, when the emission is adequate, is controlled by the electric field produced there by the grid and anode charges, passes out towards the grid and anode. In doing so the electrons acquire high speeds and shoot through the holes in the grid and are collected by the anode. Practically only the electrons which leave the filament opposite a grid wire are caught by the grid when positively charged When the grid is at a negative potential it does not collect electrons at all. It is because the grid is efficient in attracting electrons, but inefficient in catching them that the current variations produced by changes of grid potential are registered mainly in the anode current and not in the grid current If a triode were not evacuated but were filled with a gas at atmospheric pressure the electrons, moving comparatively slowly, would follow the lines of electric force and the thermionic current would be divided between the grid and anode in the ratio of their respective electric charges. For the case mentioned above in which grid and anode potentials were identical, the grid current would be m times the anode current.

If the filament, grid and anode are represented as conductors 1, 2, 3 respectively the charge on the filament Q_f may be written

$$Q_f = C_{12}v_g + C_{13}v_a, \qquad (5)$$

where the C's represent capacity coefficients and v_g and v_a the grid and anode potentials with respect to the filament which is assumed to be at zero potential Since the electric field E_f at the filament is directly proportional to Q_f we have

$$\frac{\partial E_f}{\partial v_g} \Big/ \frac{\partial E_f}{\partial v_a} = \frac{C_{12}}{C_{13}} = m \text{ (the amplification factor).} \qquad (6)$$

The value of m depends only on the geometrical configuration of the electrodes and, for a case in which the filament, grid and anode are parallel planes and the grid consists of equidistant

[1]British Patent No. 24850, Nov. 16, 1904, U S.A. Patent No. 803684, April 19, 1905.

[2]U.S.A. Patent No. 841387, Jan. 15, 1907

parallel wires of radius c it may be shown that

$$m = \frac{2\pi h}{d}\,\frac{1}{\log\dfrac{1}{2\sin\left(\dfrac{\pi c}{d}\right)}} \qquad (7)$$

where d is the distance between adjacent grid wires and h is the distance between the grid and the anode

For a cylindrical tube with a spiral wire grid wound on a cylinder of radius r_g it has been shown that

$$m = \frac{2\pi n r_g \log(r_a/r_g)}{\log(1/2\pi n c)} \qquad (8)$$

where n is the number of grid turns per cm length, r_a is the radius of the anode cylinder and c again is the radius of the grid wire

From (5) and (6) we may write

$$Q_f = C_{12}\left(v_g + \frac{v_a}{m}\right) \qquad (9)$$

so that, so far as the effect on the space charge is concerned, we may imagine the anode absent and the grid as being maintained at an effective potential $\left(v_g + \dfrac{v_a}{m}\right)$. In this way we are able to apply the Child-Langmuir diode formulae to the case of the triode We may regard the grid with its composite potential $\left(v_g + \dfrac{v_a}{m}\right)$ as acting approximately as the anode in the case of the diode so that for a triode the practical formulae (2) and (4) become respectively

$$i_a = \frac{2\cdot 33\times 10^{-6}\,(v_g + v_a/m)^{\frac{3}{2}}}{r_g^2} \qquad (10)$$

and

$$i_a = \frac{14\cdot 6\times 10^{-6}\,(v_g + v_a/m)^{\frac{3}{2}}}{r_g\beta^2} \qquad (11)$$

where r_g, in both cases, is the distance between the emitting plate or filament and the grid surface Such formulae, as before,

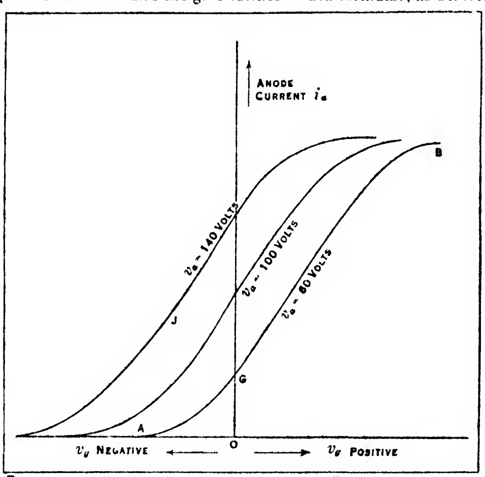

FIG 5 —SHOWING ANODE CURRENT—GRID POTENTIAL CHARACTERISTICS OF THREE-ELECTRODE VALVE

apply only to non-saturation conditions and to cases in which the current flowing to the grid (i_g) is small When i_g is appreciable (i_a+i_g) replaces i_a on the left-hand side of both equations.

From (10) or (11) we have

$$\frac{\partial i_a}{\partial v_g}\Big/\frac{\partial i_a}{\partial v_a} = -\frac{\partial v_a}{\partial v_g} = m \qquad (12)$$

and this practical expression for the value of amplification factor m is usually accepted also for conditions approaching saturation in which (10) and (11) are no longer strictly valid.

The quantity $\dfrac{\partial i_a}{\partial v_g}$ is called the differential mutual conductance of the tube and $\dfrac{\partial i_a}{\partial v_a}$ the differential anode conductance.

As with the diode the performance of a triode is usually interpreted in terms of the static characteristics For a triode the most important ones represent the relations between the anode current and grid potential for constant values of anode potential.

A set of such characteristics is shown in fig. 5 In considering it let us suppose that the anode potential is fixed at 60 volts and

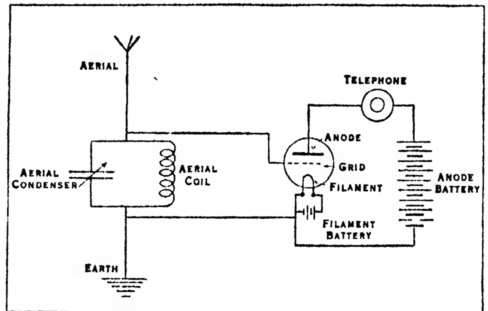

FIG 6 —ILLUSTRATING THE USE OF VALVE AS ANODE-BEND RECTIFIER

that the grid potential is zero The current flowing to the anode will then be represented by OG If the grid potential is made increasingly positive the anode current is increased until the saturation value is reached at B On the other hand when the grid potential is made increasingly negative with respect to the filament, more and more electrons are sent back into the filament and ultimately the anode current is reduced to zero, as at A For these particular conditions the negative charge on the grid is equal and opposite to that on the anode, the numerical ratio of anode and grid potentials being equal to the amplification factor m

For conditions represented by G it is evident that if the grid potential is varied symmetrically, the resulting anode current changes will be asymmetrical For such conditions the tube may therefore be used as a rectifier of wireless signals, the process

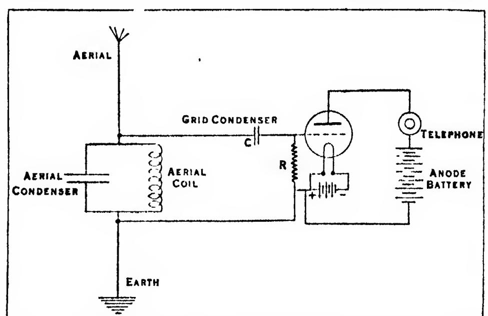

FIG. 7.—ILLUSTRATING USE OF VALVE AS CUMULATIVE GRID RECTIFIER

being termed *anode rectification*. When used in this way a typical circuit would be that shown in fig 6 which may be compared with the use of the diode as illustrated in fig 3.

The other method of using a three-electrode valve as a rectifier of wireless oscillations is illustrated in fig. 7. High frequency oscillations produced by signals received on the aerial system are transferred to the grid via the condenser C Due to the fact that the grid collects electrons during the positive half-cycles of potential, but does not do so during the negative half-cycles, the mean potential of the grid becomes negative in the course of a

signal and a diminution of anode current, the telephone responds to this as a result When the signal ceases the negative grid charge leaks away via the resistance R

If, for a tube with characteristics shown in fig 5, the anode potential is maintained at 100 volts, the relation between grid potential and anode current is, for a fair range of grid potential, sensibly linear For such a value of anode potential the tube

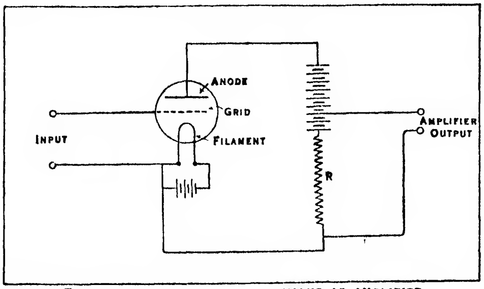

FIG 8 —ILLUSTRATING USE OF VALVE AS AMPLIFIER

could be used as an amplifier Since, however, the grid when positive attracts a certain proportion of the electric current and yet when negative does not do so, a certain asymmetry would prevent the anode current changes from reproducing faithfully the grid potential variations To obtain distortionless amplification it is usual to use a higher anode potential (*e g*, 140 volts) and shift the point representing the conditions of operation into the region of negative grid potential (*e g*, to J) by using negative grid bias

For operating conditions such as are indicated by the point J in fig 5 the characteristics are approximately linear and for sufficiently small variations may be represented by the equation

$$i_a = k_0 + k_1 v_g + k_2 v_a, \tag{13}$$

where k_0, k_1 and k_2 are constant k_1 is the differential mutual conductance while k_2 is the differential anode conductance From (12) the amplification factor is evidently $\frac{k_1}{k_2}$; also the differential internal resistance R_i is equal to $\frac{1}{k_2}$.

If a resistance R is connected in the anode circuit of a triode a change of grid voltage brings about a change in voltage across

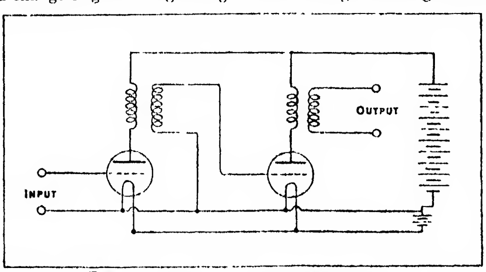

FIG 9 —VALVES WITH TRANSFORMER LINKAGE

the resistance. The ratio of the latter to the former is called the voltage magnification of the valve and circuit, and may be shown to be equal to $\frac{k_1 R}{1+k_2 R}$. As the value of R is increased the voltage magnification approaches the amplification factor of the tube m. Receiving valves have m values ranging from 2 to 120 and transmitting valves from 8 to 200.

A circuit illustrating the use of a valve for producing voltage magnification is shown in fig. 8 where a portion of the anode battery is included between the output terminals to neutralize the fall of potential across the resistance R.

The Use of Amplifying Valves in Cascade.—Thermionic valves are frequently used in cascade to secure still higher amplification The type of linkage used between one valve stage and the next depends on the particular type of electrical signal to be amplified In the majority of cases this signal is either a high-frequency alternating potential, such as a radio-frequency wireless signal, or a low frequency alternating potential such as a wireless signal after rectification Thus in a broadcast receiver

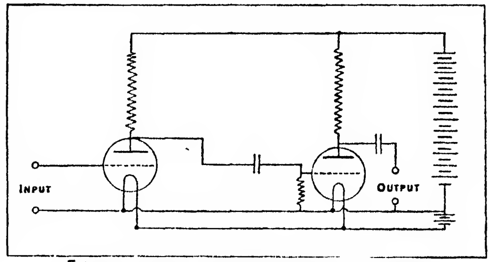

FIG 10 —VALVES WITH RESISTANCE-CAPACITY LINKAGE

we have high-frequency amplifying stages before the detector stage and low-frequency amplifying stages after the detector stage

Two methods of linkage for amplifying valves are shown in figs 9 and 10. In the first case a transformer is used to connect the anode circuit of the first valve with the grid circuit of the second In the second case the changes of potential that occur across the resistance in the anode circuit of the first valve are communicated to the grid of the second valve by means of the condenser C This method of linkage is known as resistance-capacity coupling

Both of these methods may be used for either high or low frequency amplification, but the type of transformer used in the one case and the values of resistance and capacity used in the other depend upon the frequency of the impulses to be amplified. In transformer coupling air core coils are normally used for radio-frequency amplification and iron core transformers for low or audio-frequency amplification In the case of resistance-capacity coupling the values of resistance and capacity used depend on the particular type of valve used, but in this connection it should be remembered that the linkage capacity is always considerably higher for low-frequency amplification than it is for high-frequency amplification.

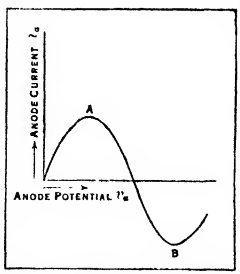

FIG 11 —SHOWING CHARACTERISTIC CURVE OF DYNATRON

The Secondary Electron Tube or Dynatron.—When electrons of sufficient energy strike a metal surface secondary electrons are emitted by the surface As the speed of the impinging electrons is increased, the number of secondary electrons emitted for each electron impact is increased and may reach values higher than unity As the majority of secondary electrons possess very small velocities, the chief factor deciding whether the electrons leave or return to the surface from which they are emitted is the direction of the electric field at that surface. Secondary emission takes place at the surfaces of both anode and grid in a three-electrode valve when these electrodes are bombarded by electrons, but the effect, however, is most strikingly marked in the case of the anode because of the much greater value of the current which reaches that electrode.

Consider a case in which the grid potential is maintained at some high potential, say 300 volts and the anode potential is

gradually increased from zero At first the anode current increases at the expense of the grid current, but, as the proportion of secondary electrons emitted by the anode increases, the collection of these secondary electrons by the grid more than counterbalances this effect and eventually the anode current falls with increasing anode potential

A typical characteristic curve is shown in fig 11 where it will be seen that between *A* and *B* the anode current falls with increasing anode potential, the differential internal resistance of the tube being negative The system, therefore, instead of dissipating energy, may be used as a source of energy and so used for maintaining or amplifying a current in a circuit (*c g*, an oscillatory circuit in a transmitter as in fig 12) which dissipates energy When used in this way the tube is called a dynatron, a name given to it by A W Hull, who first called attention to the marked effects of secondary emission for high electrode potentials

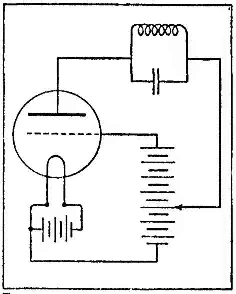

FIG 12 —SHOWING USE OF DYNATRON AS OSCILLATION GENERATOR

The Four-electrode Valve or Tetrode.—Tubes with two grids, and thus four-electrodes in all, are of two types. In both types the grids are situated between the filament and anode. In the first type the grid nearer the filament (known as the inner or space-charge grid) is maintained at a constant positive potential with respect to the filament, while the outer grid performs the normal functions of the grid in a three-electrode tube. The positive charge on the inner grid, even when the potential of the latter is low, is sufficient to neutralize the effect of space charge near the filament Thus practically the whole of the emission current leaves the filament and passes through the interstices of the inner grid For such conditions we can regard the inner grid surface as the cathode or "filament," the outer grid and anode performing their normal functions The chief advantage of this type of tube is that only low anode potentials need be used

In the second type of tetrode (the shielded grid type) the inner grid plays the part of the normal one, and the outer grid, which is usually in the form of a wire net or mesh, is maintained at a constant potential, usually a little lower than the anode potential. The function of the outer grid is to shield the inner grid electrostatically from the anode, and so prevent undesired reaction between the grid and anode circuits when the tube is used in a high-frequency amplifier.

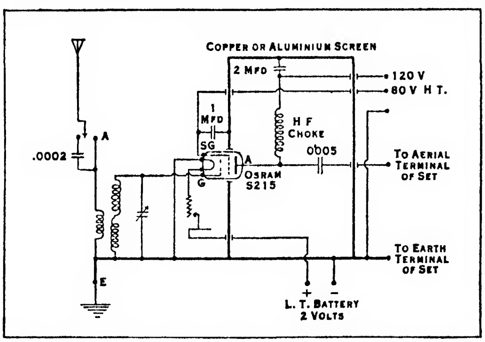

FIG 13 —SHOWING CIRCUIT FOR USE WITH SCREENED-GRID VALVE (OSRAM)

The shielding grid has, however, the further effect of shielding the filament from the anode so that variations of anode potential cause, under normal working conditions, inappreciable variations of the current leaving the filament. The result is that this type of tube has a large amplification factor and a large internal resistance. The shielding grid is usually maintained at a lower potential than that of the anode—a shielding grid potential of 80 volts, together with an anode potential of 120 volts, being commonly used. To increase the shielding effect between the anode circuit and the other electrodes it is usual to complete the shield with a metal screen as shown in fig 13 where a screened grid high-frequency stage is added to an ordinary receiver

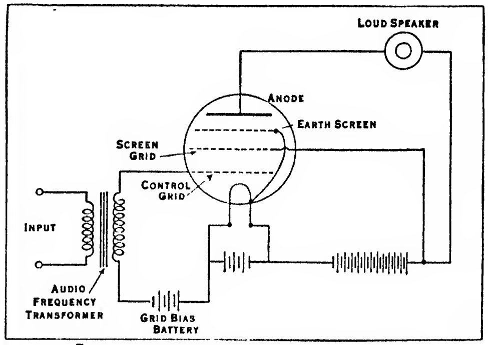

FIG 14 —ILLUSTRATING CONNECTIONS OF PENTODE

The Five-electrode Valve or Pentode.—The pentode is a screened grid valve like the screened tetrode, but includes an extra grid between the screening grid and the anode Since this extra grid is connected (*see* fig 14) internally to the filament of the valve, it is called the earth grid The function of this extra grid is to prevent the collection by the shielding grid of the low velocity secondary electrons emitted by the anode under primary electron bombardment Such collection otherwise takes place whenever the anode potential falls below that of the screening grid. The result is a tube with a high amplification factor together with a high internal resistance.

For good-quality loud speaker reproduction a mean anode current of about 15 milliamps (m a) is required, and it must be possible to vary the current substantially 12 m a. above and below this value. For this to take place, as a result of small grid potential variations, the mutual conductance of the valve should be high. This condition is fulfilled in the case of the pentode which is therefore specially suitable for the output or loud speaker valve in a wireless receiver

Soft Valves.—In certain types of valves, gas, at low pressure, is introduced into the envelope and plays an essential part in the working of the tube Gases used in this connection are helium, argon, nitrogen and mercury vapour The potentials applied to the electrodes are sufficiently high to cause the electrons to ionize the gas molecules by collision and produce positive ions. The presence of the positive ions affects the action of the tube in two ways. In the first place the ions are of opposite electrical sign to the electron space-charge, so that the effect of the latter in discouraging the escape of electrons from the region near the filament is much reduced. The presence of gas, therefore, facilitates the flow of current through the tube at lower anode potentials. The positive ions, in fact, play the same part as the positively charged inner grid in a tetrode of the first type described above. In the second place the presence of positive ions causes current to flow to the grid when the latter is charged negatively with respect to the filament. Since, however, with in-

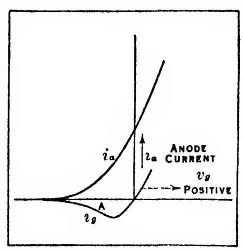

FIG. 15 —ILLUSTRATING ANODE AND GRID CURRENT CHARACTERISTICS OF SOFT VALVE

creasing negative potentials the anode current, and thus the rate at which the positive ions are produced, is decreased, the positive ion current to the grid is similarly reduced. This is illustrated by typical grid and anode current characteristics for a soft tube in fig. 15. For conditions represented by point *A* the grid filament space acts like a negative resistance, in that, with decreasing applied potential, increasing current flows, so that if an oscillatory circuit is connected across it, phenomena similar to those experienced in connection with the use of with a dynatron may be reproduced.

Indirectly-heated-cathode Valves.—In order to dispense with the use of accumulators for filament heating, valves with thick filaments, heated from the A C. supply mains, may be used. Such a practice, although successful for the amplifying stages of a receiver, is quite unsuitable for the detector stage, for which special valves have to be used if the A.C. heating is to be retained throughout These special valves have, as cathode, a nickel cylinder coated with barium or strontium oxide which is heated by the thermal radiation from a hot tungsten spiral filament inside the cylinder to a temperature sufficiently high to cause thermionic emission. Such valves are usually designated as indirectly-heated-cathode tubes. Apart from the highly specialized structure of cathode the electrodes conform very closely to normal design.

THERMIT. Thermit is a mixture of aluminium powder and iron oxide. On ignition the reaction, $8Al+3Fe_3O_4=9Fe+4Al_2O_3$ gives a temperature estimated to be between 2,300° and 2,700° Centigrade The reaction, stated in weights, means that 217 parts of aluminium plus 732 parts magnetite (iron oxide) equals 540 parts steel plus 409 parts slag, or approximately, three parts of aluminium plus ten parts of magnetite will produce, on combustion, seven parts of steel. The steel thus produced represents about one-half of the original thermit by weight and about one-third by volume.

Thermit was discovered by Dr. Hans Goldschmidt, of Essen, Germany, in 1895, while trying to reduce chromium and manganese Dr. Goldschmidt's principal discovery related to a simple and safe method of ignition, as the action of aluminium when mixed with various oxides, sulphides and chlorides was well known. Fine aluminium will not burn below the temperature of molten cast-iron, and previous experimenters had resorted to heating their mixtures in a crucible. This made the initial temperature so high at the moment of ignition that there was an explosion. Dr. Goldschmidt obtained ignition of a cold mixture by means of a barium-peroxide fuse, which was set off by a storm match. Later, magnesium powder or ribbon was used, being set off in the same way. A red-hot iron rod may also be used to set off the magnesium, which in turn ignites the thermit. Dr. Goldschmidt's original American patent No. 615700 was granted March 16, 1897, and related principally to the use of aluminium as a reducing agent for the production of carbon-free metals such as cobalt, chromium, magnesium, tungsten, etc , by what is known as the aluminothermic process. Thermit is used considerably in the foundry for purifying iron and steel in the ladle. For this purpose the thermit is placed in a can on the end of a rod and plunged to the bottom of the molten metal. The intense heat generated tends to liberate many impurities which are carried away in the slag. The principal and better-known use for thermit, however, is in the various forms of welding

Thermit Welding.—Two methods are used, known as the plastic and the fusion. The first is used for welding pipe and the latter for solid or large sections. In the plastic method, in which the thermit is used merely for heating purposes, the ends of two pieces of pipe are machined square and clamped in a cast-iron mould with the ends butted together. This mould is in two parts, so arranged that the pipe ends may be forced together when heated. The thermit is placed in an open-top crucible lined with magnesia-tar, and ignited. After the reaction takes place, the slag, which is of course lighter in weight, rises to the top of the molten metal, and is first poured into the mould. This slag forms a protective coating on the pipe and on the inside of the mould, and keeps the thermit from melting or burning through. The thermit flows into the mould and forces out the bulk of the slag, but leaves a coating as mentioned When the pipe ends become plastic they are forced together, completing the weld. After cooling, the mould is easily knocked off, since the slag coating prevents adhesion. To weld a pipe takes from $\frac{3}{4}$ to $1\frac{1}{2}$ minutes (For a detailed description of thermit fusion welding, *see* the article WELDING.) Some of the principal uses to which thermit is put are in repairing broken rudder frames, propeller shafts, locomotive frames, steel rolling-mill pinions, and other heavy sections, but it cannot be economically used for welding thin sheet metal sections. Welds have been made where from 3,000 to 4.000 lb of thermit were used For commercial purposes there are now produced three varieties of thermit, known as plain thermit, railroad thermit and cast-iron thermit. The plain thermit is simply a mixture of aluminium and iron oxide, as already given Railroad thermit is plain thermit with the addition of $\frac{5}{8}$% nickel, 1% manganese and 15% mild steel punchings. Cast-iron thermit is plain thermit with the addition of 3% ferrosilicon and 20% mild steel punchings. The various names of these mixtures indicate very closely their principal uses. (E. V)

THERMOCHEMISTRY is the name given to that branch of theoretical chemistry which seeks to trace the connection between the heat evolved or absorbed during a chemical reaction and the nature and course of the reaction. Chemical reactions which are accompanied by a great evolution of heat are familiar; the combustion of coal or gas, the reduction of iron ores by coke in the blast furnace, and the slaking of lime are common examples All explosives are unstable compounds or mixtures of compounds, the gaseous reaction products of which are raised to a very high temperature by the great heat evolved by the explosion; the propulsive force is due to the great pressure exerted by the gaseous products, owing to the high temperature and to the small volume they occupy before expansion Such reactions are familiar because their effects are so obvious They take place so rapidly that the heat evolved cannot be dissipated without raising the products of the reaction to a high temperature. It is the effects of the high temperature that are noticed, rather than the fact that large amounts of heat are evolved. In the rusting of iron we have an example of a chemical reaction which is also accompanied by the evolution of much heat; but this fact escapes ordinary notice since the rusting usually takes place so slowly that the heat has time to dissipate without perceptibly raising the temperature of the metal. If, however, finely divided iron filings are dropped into pure oxygen, the reaction takes place so suddenly that there is no time for the heat to get away before the particles get white hot.

Confronted with so many every-day examples of chemical reactions accompanied by evolution of heat, it is natural to assume a close connection between the energy changes and the material changes. For a long time, however, the interest of chemists was mainly occupied by material changes only. Following the general recognition of the law of conservation of matter and the gradual acceptance of Dalton's atomic theory in the early part of the 19th century, there was a great development of knowledge of the properties and composition of different chemical substances and of their action on each other The real development of modern thermochemistry may be said to start from the recognition of the law of conservation of energy in the middle of the century. Somewhat earlier Thomas Andrews and Hess had systematically studied the thermal effects of chemical reactions taking place in solution, and Hess, as a result of his work, had formulated a law which is one of the consequences of the conservation of energy, namely, that the thermal effect of a chemical reaction is the same however it takes place.

Law of Conservation of Energy.—According to the law of

conservation of energy, energy, though it can exist in many forms, is indestructible. No method is known by which it is possible to create energy out of nothing No system is known from which it is possible to obtain useful work without an exactly corresponding diminution in the total energy of the system. If the system is restored to its original condition by the addition of heat, then the heat absorbed is found always to be exactly proportional to the amount of work performed by the system. A few specific examples will illustrate the application of the law to chemical processes

(*a*) Heat is necessary to convert water at its boiling point into steam at the same temperature. A small part of this heat goes to perform work through expansion against atmospheric pressure, the major part is transferred into internal energy of steam molecules. The internal energy of unit mass of water vapour is therefore considerably greater than that of unit mass of liquid water at the same temperature When steam is condensed again to water, exactly the same amount of heat is evolved as was absorbed when it was formed

(*b*) A chemical reaction, such as the combustion of petrol, can be made to take place without performance of useful work, *e g.*, by allowing it to take place in a closed vessel The heat evolved by the combustion of unit weight to carbon dioxide and water vapour under these conditions can be accurately measured When petrol is burnt in an internal combustion engine, the power output (and therefore the useful work performed by combustion of unit weight), the loss of heat to the cylinder walls and the residual heat in the exhaust gases can all be measured. The sum of the heat loss to the cylinder walls, and the residual heat in the exhaust gas is always less than the total heat of combustion by an amount which is the equivalent of the work done

(*c*) A solution of copper sulphate will react with zinc, dissolving it and depositing copper The heat evolved by the solution of an "equivalent" of zinc can be measured In the Daniell cell, which consists of a zinc electrode dipping into zinc sulphate solution in a porous pot, surrounded by another container where a copper electrode dips into copper sulphate solution, this chemical reaction takes place in such a way that it can yield an electric current We can obtain work from such a cell, *e g.*, by using it to drive a small electromotor. The work can be measured accurately If E is the electromotive force (volts) and C the current (ampères), then work done is EC units per second While the current is passing we can measure the heat changes in the cell itself These are found to be small, but not zero If we express in heat units the electrical work done by the solution of unit mass, and add (or subtract) the simultaneous evolution (or absorption) of heat in the cell, we obtain a result which is the same as that obtained when the simple reaction was allowed to take place without the production of electrical energy. Alternatively, we could join the two electrodes with a wire and measure the heat produced in the wire by the passage of the electric current and the heat produced in the cell itself at the same time. The sum of these two would be the same as the heat produced by dissolving the same weight of zinc in a similar solution of copper sulphate, but by arranging the experiment in this way, most of the heat appears outside the solution instead of inside it

It will be observed that the applications of the principle of conservation of energy depend on the assumption that a unit of one kind of energy always bears a constant relation to a unit of any other kind of energy This is a necessary deduction from the law. If a mass of m grams is held h centimetres above the earth's surface, its *potential energy* is measured by the product mgh, where g is the constant of gravity and mg the force (in dynes) with which the earth attracts it If it is allowed to fall freely, and we neglect the resistance of the air, it will have a velocity of v centimetres per second just before hitting the earth Its potential energy has then been entirely converted into ***kinetic energy*** which is measured by the product $\frac{1}{2}mv^2$. As no energy is lost, $\frac{1}{2}mv^2 = mgh$ and $v = \sqrt{2gh}$. When it hits the earth its kinetic energy is entirely converted into heat, and the amount of heat produced is exactly proportional to $\frac{1}{2}mv^2$, or to mgh The potential energy is so called because, if the restraining force is removed, the mass acquires kinetic energy if left to itself. The energy is originally latent and only becomes apparent when the restraining force is removed; we can speak similarly of ***latent*** chemical energy.

Every element and every chemical compound has a definite content of energy which varies with the temperature. We know it varies with the temperature, because if we want to raise the temperature of anything we have to put heat into it We do not know, however, what is the total energy content of any chemical substance, nor how it is divided up within the molecules; what we can determine is the *change in total energy* content which takes place during chemical reactions, and we can express the law of conservation of energy, in its application to chemistry, in the form

$$U = A - Q,$$

where U is the diminution in total energy content accompanying a chemical reaction, A is the work done during or by means of the reaction, and Q is the actual measured absorption of heat during the reaction In applying this equation it is necessary to express all quantities in the same units A, the work done by a chemical reaction, is usually either mechanical work, as in the internal combustion engine, or electrical work, as in the accumulator. The unit of mechanical work in the C.G.S system is the ***erg***, the unit of heat is the *calorie*, which is the amount of heat necessary to raise the temperature of 1 gram of water from 15° to 16° C The expenditure of $4\,18 \times 10^7$ ergs, or 4 18 *joules* will produce 1 calorie of heat.

Determination of Total Energy Changes.—The realization that the total energy content of a chemical substance was a property of the substance as important as any other property, and that the changes in energy accompanying chemical reactions were closely connected with the nature of the reaction, led to a very large number of experimental determinations of heats of reaction by J Thomsen and M Berthelot Heats of reaction are determined in principle by causing the reaction to take place rapidly under such conditions that its heat is transferred to a large and well stirred volume of water, which is thereby raised a few degrees in temperature As the specific heat of water is by definition unity at 15° C, the heat evolved can be calculated if the mass of water and its rise in temperature are accurately known Allowance must be made for the actual heating of the containing vessels and the reacting substances, and also for the loss of heat during the time the reaction takes place This loss of heat is kept down by keeping the rise in temperature small, which necessitates the use of very sensitive thermometers. Accurate calorimetry depends essentially on making proper allowances for this loss of heat, or alternatively on methods employed to counterbalance it. In general the data given in chemical literature cannot be relied upon to within $\frac{1}{2}$%, and in many cases the error of determination is much greater An experimental error of this order may be serious in certain cases, as we shall see later.

It is necessary to distinguish between heats evolved when reactions take place at constant pressure and at constant volume Only the latter accurately correspond in all instances to the change in total energy due to the reaction If the reaction is allowed to take place at constant (atmospheric) pressure and there is a change in volume due to the reaction, then work is done, and the measured heat of reaction will not be the same as the change in total energy. In the case of reactions taking place between solids or liquids the difference is usually negligible; in cases of gases the necessary correction can be easily applied For instance, in the combustion of methane to carbon dioxide and liquid water, $CH_4 + 2O_2 = CO_2 + 2H_2O$, three volumes of mixture react to form one volume of carbon dioxide and a negligible volume of liquid water. This diminution of volume means that at constant pressure work is performed by the atmosphere This work reappears as additional heat in the calorimeter. If we take the volume of one mol. of gas (22·4 litres) as the unit volume, the work done, $2P \times V$, according to the gas laws $= 2\,RT$, where R, the gas constant, is approximately 2 when the work is expressed in heat units, and T is the absolute temperature. Thus the heat of combustion of methane, measured at 18° C (or 291° absolute), should be approximately 1,200 calories higher when the combustion takes place at constant pressure, *e.g.*, when the gas is burnt in a jet, than when the mixture is burnt in a completely closed vessel. If, however, the

combustion takes place above 100° C so that no water vapour condenses, there is no change of volume, and no difference between the heats evolved at constant volume and constant pressure.

Indirect Determination.—Many heats of reaction are difficult if not impossible to measure directly. This is true of most reactions in organic chemistry which either do not take place rapidly enough to allow of accurate measurement, or yield other products besides those under investigation. But if the heats of combustion of organic compounds are known, the heat of any conceivable reaction between such compounds can be estimated by means of the first law. Take, for example, the technically important formation of methyl alcohol from carbon monoxide and hydrogen which proceeds according to the equation, $CO+2H_2=CH_3OH$ The heat of combustion of 1 mol. of carbon monoxide to carbon dioxide at constant pressure is 68,300 calories. The heat of combustion of 2 mols of hydrogen to *liquid* water at constant pressure is $2\times68,400$ calories $=136,800$ calories. The heat of combustion of 1 mol. of methyl alcohol in the form of vapour to carbon dioxide and liquid water is 182,000 calories Now the total change in energy must be the same whether the carbon monoxide and hydrogen are burnt directly to carbon dioxide and water, or whether they are first transformed into methyl alcohol and then burnt. Hence the heat evolved when carbon monoxide and hydrogen unite at constant pressure to give methyl alcohol in the form of vapour is.

$$68,300+136,800-182,000=23,100 \text{ calories}$$

This example will serve to show the importance of accuracy in calorimeter measurements. For suppose Thomsen, whose figures have been taken, underestimated the heats of combustion of carbon monoxide and hydrogen by 1%, and overestimated that of methyl alcohol by 1%, the corrected figure for the heat of reaction to methyl alcohol would then be $69,000+138,200-180,200=27,000$ calories, which is nearly 20% higher than the estimate made on the basis of Thomsen's recorded results

Variations Due to Physical Conditions.—Since the intrinsic (total) energy of a substance varies with the conditions under which the substance exists, it is necessary in recording the mechanical data to specify the conditions of the initial and final systems Besides change of volume, the following conditions have to be considered: (1) Dilution of solutions. (2) Physical state. (3) Temperature.

(*1*) *Dilution of Solutions*—Generally speaking, there is a considerable thermal effect when a substance is dissolved in water, and this effect varies in magnitude according to the amount of water employed It is only, however, when we deal with comparatively concentrated solutions that the heat-effect of diluting the solutions is at all great, the heat-change on diluting an already dilute solution being for most practical purposes negligible. In dealing, therefore, with dilute solutions, it is only necessary to state that the solutions are dilute, the exact degree of dilution being unimportant It occasionally happens that a change in dilution affects the chemical action that occurs. Thus, if concentrated instead of dilute sulphuric acid acts upon zinc, the action takes place to a great extent not according to the equation $Zn+H_2SO_4=ZnSO_4+H_2$, but according to the equation $Zn+2H_2SO_4=ZnSO_4+SO_2+2H_2O$, sulphur dioxide and water being produced instead of hydrogen Here we have a different final system with a different amount of intrinsic energy, so that the thermal effect of the action is altogether different.

(*2*) *Physical State.*—The physical state of the reacting substances must be considered, since comparatively large amounts of heat are absorbed on fusion and vaporization. Thus the heat of fusion of ice (for 18 grams of H_2O) is 1,440 cal., and the heat of vaporization of water at 100° for the same quantity is 9,670 cal. When a substance, *e g*, carbon, phosphorus, sulphur, exists in allotropic forms, the particular variety employed should always be stated, as the conversion of one modification into another is frequently attended by a considerable thermal effect. Thus the conversion of white into red phosphorus evolves about one-sixth of the heat of combustion of the latter in oxygen, and so the knowledge of which variety of phosphorus has been employed is of essential importance in the thermochemistry of that element. (*See* ALLOTROPY.)

(3) *Influence of Temperature.*—The influence of temperature on the thermal effects of a chemical reaction is sometimes considerable. If we know the change in total energy associated with any reaction at one temperature, the first law enables us to calculate it for any other temperature. If, for example, the total energy content at temperature T_1 is U_{H_2} for 1 mol. of hydrogen, U_{O_2} for 1 mol of oxygen, and U_{H_2O} for 1 mol of water vapour, the change in total energy due to the combination of hydrogen and oxygen to form 2 mols of water vapour is, say,

$$2U_{H_2}+U_{O_2}-2U_{H_2O}=U_{T_1}.$$

If we raise the temperature of 1 mol. of hydrogen (etc) from T_1 to T_2, its total energy is increased by $(C_v)_{H_2}(T_2-T_1)$, where $(C_v)_{H_2}$ is the mean capacity for heat of 1 mol of hydrogen at constant volume between the temperatures T_2 and T_1 This is simply a definition of what we mean by *molecular specific heats* Hence the total energy change at the higher temperature T_2 is·

$$2\{U_{H_2}+(C_v)_{H_2}(T_2-T_1)\}+U_{O_2}+(C_v)_{O_2}(T_2-T_1)$$
$$-2\{U_{H_2O}+(C_v)_{H_2O}(T_2-T_1)\}=U_{T_2}$$
$$\therefore\quad U_{T_2}-U_{T_1}=(T_2-T_1)\{2(C_v)_{H_2}+(C_v)_{O_2}-2(C_v)_{H_2O}\}$$

We can express this most simply by saying that the rate of change of U with the temperature (dU/dT) is equal to the sum of the heat capacities of the reacting compounds minus the sum of the heat capacities of the products of the reaction

Thermochemical Measurements.—Some general results of thermochemical measurements applied to heats of combustion, neutralization and solution may now be considered.

(*a*) *Heats of Combustion*—Experiment has shown that the heat of combustion of organic substances of various kinds varies regularly with the molecular weight. The difference between the heats of combustion of two neighbouring members in a series of homologous compounds is practically constant, and the value of the constant shows very little variation as we pass from one series to another Thus the heat of combustion of methane, CH_4, to carbon dioxide and liquid water at constant pressure is 212,000 calories; of ethane, C_2H_6, is 370.500 calories, a difference of 158,500 calories, of propane, C_3H_8, is 529.200 calories, which is 158,700 above that of ethane, and the heat of combustion of all paraffin hydrocarbons (C_nH_{2n+2}) can be expressed by the formula $212,000+158,500\ (n-1)$ or $158,500\ n+53,500$ calories, where n is the number of carbon atoms in the molecule, and the mass to which the heat of combustion refers is the molecular weight in grams of the compound

Similarly the heat of combustion of alcohols $C_nH_{2n+1}OH$, can be expressed by the formula.

$$183.000+158.800\ (n-1)$$

or

$$158,000n+34.200 \text{ calories.}$$

As a rule the addition of a CH_2 group to any organic molecule will increase the molecular heat of combustion by about 158.800 calories, but the rule is not exact, and the actual figure varies somewhat from series to series. In particular the heat of combustion of two isomeric substances, *i e.*, substances with the same number of carbon, hydrogen, oxygen, etc., atoms in the molecule, but differently arranged, are very nearly but not exactly the same. It follows that there are similar regularities in the *heats of formation* of organic compounds, for the heat of formation is the difference between the heat of combustion of a compound and the total heats of combustion of the carbon, hydrogen, etc., it contains.

(*b*) *Heats of Neutralization.*—The heats of neutralization of acids and bases in aqueous solution are additively composed of two terms, one being constant for a given base, the other constant for a given acid. In addition to this the further regularity has been observed that, when the powerful monobasic acids are neutralized by the powerful monacid bases in dilute solution, the heat of neutralization is in all cases the same. The following table gives the heats of neutralization of the commoner strong monobasic acids with soda:

	Formula	Cal
Hydrochloric acid	HCl	137,400
Hydrobromic acid	HBr	137,500
Hydriodic acid	HI	136,800
Nitric acid	HNO_3	136,800
Chloric acid	$HClO_3$	137,600
Bromic acid	$HBrO_3$	137,800

Within the error of experiment these numbers are identical.

It was at one time thought that the greater the heat of neutralization of an acid with a given base, the greater was the strength of the acid It is now known, however, that when weak acids or bases are used, the heat of neutralization may be either greater or less than the normal value for powerful acids and bases, so that there is no proportionality, or even parallelism, between the strengths of acids and their heats of neutralization (*see* CHEMICAL ACTION)

(*c*) *Heats of Solution* —When substances readily combine with water to form hydrates, the heat of solution in water is usually positive; when, on the other hand, they do not readily form hydrates, or when they are already hydrated, the heat of solution is usually negative The following examples show the effect of hydration on heat of solution in a large quantity of water:

I *Sodium Carbonate*

	Heat of solution	Heat of hydration
	cal.	cal.
Na_2CO_3	+ 5,640	
Na_2CO_3,H_2O	+ 2,250	+ 3,390
$Na_2CO_3,2H_2O$	+ 20	+ 5,620
$Na_2CO_3,10H_2O$	−16,160	+21,800

First and Second Laws of Thermodynamics.—It should be clearly realized that the *law of conservation of energy,* like the law of conservation of mass, is a statement of experimental observations and in chemistry admits of no exception. All recorded observations support the law within the unavoidable errors of experiment, all deductions from the law have been amply verified. Apparent limitations of the law have been brought to light by recent physical research, and in particular through Einstein's famous theory of relativity (*q v*), but in ordinary chemistry we do not deal with atomic or ultra-atomic changes, but with molecular rearrangements, and the laws of conservation of energy and mass, as originally conceived, still hold good

Reversible Chemical Reactions —As the result of the large number of experiments made by them, Thomsen and, later, Berthelot expressed the opinion that heat of reaction must be regarded as a measure of chemical affinity, and that every chemical change tended to take a course which evolved the maximum amount of heat Berthelot in particular regarded this as a general guiding principle in chemistry, and impressed its importance so much on others that it continued to be upheld long after Berthelot himself had recognized its error. It is not easy now to realize why this "principle" commanded such universal acceptance; simple physical transformations which took place spontaneously either with absorption or evolution of heat, according to the circumstances, must have been familiar For instance, water will freeze spontaneously and in doing so will liberate thermal energy if the temperature is below 0°. Above 0° ice melts spontaneously and in doing so absorbs heat from its surroundings. Further, even at the time Berthelot put forward his theory, there was a growing recognition of the fact that many *chemical reactions are reversible, i.e*, that they take place either in one direction (with evolution of heat) or in the opposite direction (with absorption of heat), according to the conditions of temperature and pressure and the relative masses of the reacting substances. So long ago as 1801, the great French chemist Berthollet had introduced the idea of "chemical equilibrium," and in the same year that Berthelot put forward his erroneous theory (1867) Guldberg and Waage published their famous book on chemical affinity, which dealt with reversible chemical reactions and in which they put forward the *law of chemical mass action*

Chemical Equilibrium.—This law, in so far as chemical equilibrium is concerned, may be formulated as follows. Suppose chemical substances, A_1, A_2, etc., react to form B_1, B_2, etc. The reaction tends to proceed until a condition of equilibrium is set up, governed by the equation

$$\frac{[A_1]\times[A_2]\times \text{etc.}}{[B_1]\times[B_2]\times \text{etc}} = K.$$

where $[A_1]$, etc., represents the concentration of the compound A_1, etc., in the equilibrium mixture On the other hand, if the compounds B_1 and B_2 are originally brought together, then the reaction will proceed in the reverse direction with production of A_1 and A_2 until the same condition of equilibrium is set up The value of the *equilibrium constant* K is itself independent of concentration—for example, in the case of gaseous reactions it is independent of pressure—but it varies with the temperature Clearly such constants are of great significance in the study of chemical affinities. If K is very small, then the affinity of A_1 for A_2, etc, may be said to be very great, and the affinity of B_1 for B_2, etc., small, although not zero

The important thing to notice is that every single instance of a reversible chemical reaction really disproves the Berthelot principle. Nevertheless, the principle has this much to be said for it, that most chemical reactions which take place spontaneously at low temperatures do so with evolution of heat, and that it is only when the effects of high temperatures are studied that we become really familiar with important reactions that take place spontaneously with absorption of heat. There is one such reaction that is made use of daily on an enormous scale for the production of heat, namely, the reaction between steam and coke at a bright red heat to yield "water gas," a mixture of approximately equal volumes of hydrogen and carbon monoxide. As the reaction proceeds the coke cools, and at regular intervals it is necessary to shut off the supply of steam, and to pass air over the coke in order to raise it again by combustion to a temperature sufficiently high to allow the reaction with steam to continue rapidly It is true that the cooling of the coke during the passage of steam is not entirely due to the chemical reaction, for it is partly accounted for by the cooling effect of the steam itself, which is introduced to the retort at a lower temperature than the coke. But even if the steam were initially at the same temperature as the coke, it would be found that the mass gradually cooled. The spontaneous formation of nitric oxide by the passage of air through an electric arc, a process by which nitric acid is manufactured on a large scale, is also accompanied by absorption of heat. Pure nitric oxide, on the other hand, decomposes into its elements, nitrogen and oxygen, at a somewhat lower temperature with evolution of heat Hydrogen and oxygen will combine explosively and completely at low temperatures; but steam is found to decompose spontaneously though not completely into hydrogen and oxygen if it is heated to a temperature above 2,000° C, and heat is absorbed during the decomposition. Clearly, therefore, the heat evolved during a chemical reaction cannot give a direct measure of the affinity of the reacting substances.

The first big practical advance that was made in our knowledge of the relations between thermal changes and chemical affinity was due to van't Hoff's demonstration that the law of mass action was a necessary consequence of the second law of thermodynamics and of the quantitative connection between the value of the "equilibrium constant" and the change in total energy due to the reaction. The second law of thermodynamics, like the first, is a statement of experience, perhaps one might say a collection of inter-related statements of experience. The first law states that it is impossible to create energy; the second law states that it is im-

possible to convert the heat energy of our surroundings continuously into useful work. The second law deals with a question which the first law does not answer, namely, under what conditions can heat energy be converted into useful work (that is to say, mechanical energy). If heat energy passes spontaneously from one body to another, the first body is said to be at a higher temperature. It is a matter of universal experience that the reverse change, *i.e.*, the passage of heat from one body to another of higher temperature never takes place spontaneously. It is also a matter of experience that any spontaneous process can be made to yield a definite amount of useful work. For instance, the cooling of a furnace is a spontaneous process By the use of steam and suitably designed engines, it is possible to obtain useful work from this process.

Carnot's Definition.—The question how much useful work can be obtained by the spontaneous passage of heat from one temperature to another is of fundamental importance not only in mechanical engineering but in the science of chemistry. Carnot, a French engineer, actually solved this problem in 1824 before the law of conservation of energy was universally accepted. He showed that the maximum amount of work which can possibly be obtained from the "spontaneous" transference of a quantity of heat Q from a reservoir at temperature T_1 to another of the lower temperature T_2 was $Q(T_1-T_2)/T_1$. It will be noted that Carnot's result involves a quantitative definition of "absolute" temperature. The so-called "thermodynamic scale of temperatures" which is implicit in his result, is based on the behaviour of a perfect gas, the energy content of which is independent of its volume and dependent only on the temperature The absolute temperature of a perfect gas is defined by the fundamental gas law $T=PV/R$, where P is the gas pressure, V its volume, and R a constant. The value of R depends on the units in which the pressure and volume are expressed. Many gases approach very nearly the properties of the imaginary "perfect" gas, particularly at low densities.

The next point of interest is that Carnot in deriving his result imagined a perfectly frictionless engine, with a perfect gas as a working fluid, taking heat from the high temperature reservoir (as steam takes heat from a furnace), converting part of the heat into work, and rejecting the rest to the low-temperature reservoir The argument is that such an engine will always yield the maximum amount of work, because if it is reversed, the expenditure of work, only infinitesimally greater in amount than the engine yields on the direct operation, will suffice to restore the heat from the low temperature to the high temperature reservoir. For suppose it was possible to make another reversible and frictionless engine which was capable of converting a greater proportion of the transferred heat into work. Then it would be possible to use part of the work yielded by this change to reverse the first engine, and to restore the whole system to its original condition, leaving a definite amount of work over which has been created out of nothing. This is contrary to the first law Hence we say that the work that can be done by a perfectly efficient reversible engine or process is independent of the nature of the process.

The Gibbs-Helmholtz Equation.—This conclusion leads to a mathematical expression of the first and second laws of thermodynamics in a form which can be applied to all chemical as well as other phenomena. For if, instead of having a perfect engine to transfer heat from the reservoir at $T+dT$ to another at T, we allow a chemical process to take place in the first reservoir, yielding a maximum amount of work A and absorbing heat from the reservoir equal to Q, and we then reverse this chemical process in the second reservoir by the expenditure of $A-dA$ of work, we have gained an amount of work$=dA$, and if the process is conducted reversibly this work must be equal to that gained by any other perfect process; in other words, $dA=Q{\cdot}dT/T$. But Q, the heat absorbed, is equal (by the law of conservation of energy) to the maximum work A, less the diminution in total energy U, *i.e.*,

$$dA=(A-U)dT/T,$$
$$\text{or } A-U=T{\cdot}dA/dT.$$

This is the relation which was deduced independently by Helmholtz and Willard Gibbs. The quantity A is the maximum amount of work that can be obtained from a (reversible) chemical process taking place spontaneously and at constant volume at the temperature T; $A+dA$ is the work that would be obtained by allowing it to take place at the same volume at the higher temperature $T+dT$; and U is the diminution of total energy which corresponds to the heat evolved when the reaction takes place without the performance of any work, *e g*, in a closed vessel. A is often known as the *decrease in free energy*, to distinguish it from U, the *decrease in total energy*.

The most direct use of this equation is found in its application to the electric cell or battery. For the electric cell is a contrivance for converting chemical energy into useful work If the cell is reversible, the work will be the maximum obtainable from the chemical reaction which is the source of the electric current What we mean by a reversible cell is that, if a potential infinitesimally greater than that yielded by the cell is applied to the electrodes, the current will travel in the reverse direction in the cell and the chemical reaction will be reversed. The lead accumulator is nearly reversible in this sense; so is the Daniell cell The electromotive force of the Daniell cell is found to be 1·1 volts. For every gram-equivalent of copper deposited and zinc dissolved in the cell, an amount of work is done$=EF$, where F is the quantity of electricity (96,540 coulombs) associated with one gram-equivalent These units can be expressed in calories; calculation shows that if E is the potential, the work done by the reaction is 23,050E calories Hence the work done by the Daniell cell is 25,260 calories per gram-equivalent of copper deposited. The heat of the reaction, when it takes place without performance of work, is found to be 25,060 calories. Hence in this case $A=U$ nearly. We should find therefore that dA/dT, or dE/dT, which is the change of electromotive force with the temperature, is very small. Measurement shows that it is only 0·000034 volt per degree

Lord Kelvin put forward the view in 1851 that the electromotive force of a cell could always be calculated from the heat of the chemical reaction, that is to say from the decrease in total energy This "law" involves the assumption that no chemical reaction can be made to yield electrical energy unless it is accompanied by a decrease in total energy It holds approximately for the Daniell cell, and for others such as the standard Weston cell. The Helmholtz equation shows that it can only be true when the electromotive force does not change with the temperature. We are familiar now with cells which yield an electric current even if the chemical reaction is associated with an absorption of heat; we know of cells the voltage of which increases with temperature, and others in which it decreases None of these cells obeys Kelvin's law, but the behaviour of all of them can be shown to be in exact accordance with the Helmholtz equation The study of electric cells provides the most interesting and exact confirmation of the fundamental laws of thermodynamics.

The Van't Hoff Equation.—Apart from the combustion of coal and oil, most chemical reactions interest us more from the point of view of the nature of their products than from that of the work obtainable from them. As all chemical reactions are in principle reversible, and as many of the more important from a practical point of view can be made to proceed in one or the other direction according to conditions of temperature and pressure, it is not only of theoretical interest but of great technical importance to get an accurate picture of the relations between chemical equilibrium and thermal changes Van't Hoff succeeded in doing this by calculating the maximum work that could be obtained from a chemical reaction taking place between gases, by the use of an imaginary "ideal" process By the application of the second law two important results emerged:

(1) *The law of mass action*, first deduced from consideration of molecular theory, was shown to be a necessary consequence of the thermodynamical laws, that is to say, if a state of equilibrium exists between gases according to the chemical equation

$$n_1\mathrm{A}+n_2\mathrm{B}+\text{ etc.}=n'_1\mathrm{A}'+n'_2\mathrm{B}'+\text{ etc.}+U\text{ calories,}$$

then
$$\frac{[\mathrm{A}]^{n_1}\times[\mathrm{B}]^{n_2}\times\cdots}{[\mathrm{A}']^{n'_1}\times[\mathrm{B}']^{n'_2}\times\cdots}=K.$$

(2) *The equilibrium constant* K was shown to be connected with the temperature and the decrease in total energy through the equation

$$d \log_e K/dT = U/RT^2$$

In practical applications it is usually more convenient to express the quantities of gases present in an equilibrium mixture in terms of their partial pressures instead of their concentrations. If there are N molecules of gas present altogether in a mixture which contains n_1 molecules of one kind, n_2 of another, and so on, the partial pressures are n_1P/N, n_2P/N, etc. where P is the total pressure It is simple to show that

$$\frac{P_A^{n_1} \times P_B^{n_2} \times}{P_{A'}^{n'_1} \times P_{B'}^{n'_2} \times} = K_p$$

where P_A^n represents the partial pressure of A, and the new constant $K_p = K(RT)\Sigma_n$, Σ_n being the difference between the number of the reacting molecules and the total number formed by the reaction. $d \log_e K_p/dT = Q_p/RT^2$. It can also be easily shown that where Q_p is now not necessarily the diminution in total energy, but corresponds to the heat evolved when the reaction takes place at constant pressure, without the performance of any work other than that due to the change of volume, if any, associated with the reaction This equation is similar to that found to hold good for the change of vapour pressures of liquids (and solids) with the temperature, *viz*, $d \log_e p/dT = \lambda/RT^2$, where λ is the latent heat of evaporation of one gram-molecule of the liquid or solid

Some Thermochemical Reactions.—The application of these equations to chemistry inaugurated a new era, and led not only to a rapid extension of our knowledge of chemical reaction, but also to the recognition of the connection between many apparently diverse phenomena. Some illustrations of the use of the equations will now be given

Hydrogen and oxygen combine to form steam with evolution of heat according to the equation

$$2H_2 + O_2 = 2H_2O + 116{,}000 \text{ calories.}$$

If we start with 2 mols of hydrogen and 1 mol of oxygen, then according to the law of mass action an equilibrium will be reached when $2(1-x)$ mols of water vapour are formed, and $2x$ mols of H_2 and x mols. of O_2 are left uncombined Supposing the volume occupied is v, then the law states that at equilibrium

$$\frac{(\text{Concn of } H_2)^2 \times (\text{Concn of } O_2)}{(\text{Concn of water vapour})^2} = K$$

or

$$\frac{\left(\frac{2x}{v}\right)^2 \times \frac{x}{v}}{\left\{\frac{2(1-x)}{v}\right\}^2} = K \text{ or } \frac{x^3}{(1-x)^2} \times \frac{1}{v} = K$$

Now at ordinary temperatures, the amount of hydrogen and oxygen left uncombined is very small and escapes direct measurement. As x is small, K is also small. But van't Hoff's equation shows that, as U is large and positive, log K, and therefore K, increases with the temperature. Hence x increases with the temperature. In other words, water vapour will dissociate when the temperature is raised.

This result may be generalized All compounds which are formed with evolution of heat tend to decompose when the temperature is raised. The same applies to molecules such as H_2, O_2, N_2, Cl_2, I_2, etc, which are formed from their atoms with evolution of heat Conversely, compounds which are formed with absorption of heat become more stable at high temperatures Nitric oxide cannot be made from nitrogen and oxygen at low temperatures, but is formed when air is blown through an electric arc Hydrogen peroxide may be detected in an oxy-hydrogen flame. Calcium carbide is formed in an electric furnace at a very high temperature If v in the equation given above is made smaller, then x must also diminish, because K is constant High pressure tends, therefore, to assist combination or to prevent dissociation. This is the case whenever the reaction is accompanied by a decrease in the number of molecules The synthesis of ammonia is an important technical example. Here one molecule of nitrogen combines with three molecules of hydrogen to form two of ammonia, $N_2 + 3H_2 = 2NH_3$. The mass action equation is

$$27x^4/4(1-x)^2v^2 = K,$$

where x is the fraction of nitrogen left over If the value of v is diminished, x must also be diminished, and the amount of ammonia formed increases. As is well known, the commercial success of the process depends on very high pressure being used If no change in the number of molecules is caused by a reaction, v cancels out, and therefore an alteration in the pressure has no effect on the equilibrium If the number of molecules is increased, v appears in the numerator instead of the denominator, and an increase of pressure will then have the opposite effect.

The effects of pressure and temperatures on equilibrium can be generalized in the statement that the equilibrium will always adjust itself in such a way as to oppose a change in physical conditions If the pressure is increased, the equilibrium will shift in the direction of smaller volume When heat is added that reaction will take place which results in an absorption of heat, thus tending to stop a rise of temperature The same applies to physical processes Water expands when it freezes; if we compress ice at the freezing point it will do its best to diminish its volume by melting Liquids always absorb heat when they evaporate, if heat is added to water which is boiling at atmospheric pressure, its temperature is not increased All that happens is that it boils faster

If a reaction between gases is studied experimentally at any one temperature and pressure, so that the equilibrium conditions are known, then the effect of a variation in pressure at that temperature can be accurately calculated provided the mixture obeys the "perfect gas" laws If the heat of reaction is also known at that temperature, then the equilibrium for any other temperature not too far removed can be calculated from van't Hoff's equation. For integration of the equation gives

$$\log_e K = -U/RT + \text{constant},$$

if U does not change much with the temperature Hence if K_1 and K_2 are the equilibrium constants at temperatures T_1 and T_2

$$\log_e K_1/K_2 = U(1/T_2 - 1/T_1)/R$$

Gases and Solids.—Chemical reactions in which gases and solids take part present features of special interest To take a simple example, carbon dioxide combines with lime to form calcium carbonate with evolution of heat:

$$\underset{\text{solid}}{CaO} + \underset{\text{gas}}{CO_2} = \underset{\text{solid}}{CaCO_3} + 42{,}500 \text{ calories}$$

Now the pressure of saturated vapour above any solid or liquid is independent of the amount of solid or liquid present, unless the amount is very minute If a closed space contains carbon dioxide gas, in the presence of solid calcium oxide and carbonate, there will be an equilibrium in the gaseous phase governed by the relation

$$\frac{(\text{Concn. of CaO vapour}) \times (\text{Concn of } CO_2)}{(\text{Concn. of } CaCO_3 \text{ vapour})} = K.$$

As the concentrations of the vapours of the two solids are constant (though extremely small) at any given temperature, it follows that the concentration of carbon dioxide must also be constant. In other words its pressure is constant. Above a mixture of calcium oxide and carbonate we have, therefore, our apparent "vapour" pressure of carbon dioxide, which varies with the temperature

The heat of the reaction is analogous to the heat of evaporation of any solid or liquid, and if P is the "vapour" pressure, which is called the ***dissociation pressure*** in this and similar cases,

$$d \log_e P/dT = Q/RT^2,$$

where Q is the heat of reaction, *i.e.*, the heat absorbed on dissociation of 1 gram-molecule, and includes the work done against atmospheric pressure by the evolution of 1 gram-molecule of

carbon dioxide. The dissociation pressure, like the vapour pressure of liquids, increases with the temperature. At a high temperature, about 900° C, the dissociation pressure is equal to ordinary atmospheric pressure. If the carbonate is heated above this temperature it is converted into lime and carbon dioxide is rapidly evolved.

If other carbonates are examined it is found that the temperature at which they are converted into their oxides varies directly with their heat of dissociation as the following table shows

Substance	Heat of dissociation	Temperature
	cals	°C.
Silver carbonate	20,100	225
Lead carbonate	22,600	302
Manganese carbonate	23,500	ca 330
Calcium carbonate	42,500	900
Strontium carbonate	55,800	1,150

On similar reasoning, it may be shown generally that in all reactions in which gases and solids take part, the equilibrium conditions only take account of the gases. For instance, when carbon dioxide is passed over red-hot coke it is converted into carbon monoxide with absorption of heat, $C+CO_2=2CO-38,500$ calories The equilibrium condition is

$$P_{co}/P_{co_2}=K \text{ or } d\log_e K_p/dT=38,500\ RT^2$$

from which it can be deduced (a) that the ratio CO/CO_2 in the gas mixture at equilibrium is constant if the temperature and pressure are constant; (b) that if the temperature is kept constant, and the pressure is increased, the proportion of carbon monoxide in the mixture goes down; (c) that if the temperature is increased, the proportion of carbon monoxide goes up

In the blast furnace, air is blown through a white-hot mixture of oxides of iron and coke, and the carbon monoxide formed by the combustion of coke reduces the oxides to metallic iron The exit gases must contain a large proportion of carbon monoxide to carbon dioxide, corresponding to the equilibrium conditions which obtain near the cooler top of the furnace It was at one time thought that by building furnaces higher, the period of contact between the gases and the ore would result in a greater measure of reduction, a diminished proportion of carbon monoxide in the exit gases, and consequently a smaller consumption of coke per ton of ore reduced Attempts to achieve these results, by building furnaces as high as 100 ft, failed As Le Chatelier pointed out, if there had been a better acquaintance with the laws of chemical equilibrium, these experiments would have been unnecessary. It was an expensive, although no doubt an instructive, method of proving the correctness of one of the deductions from the second law

Heat and Velocity of Reaction.—These examples will suffice to indicate how the quantitative application of simple fundamental thermodynamic principles has been successful in reducing to order an enormous range of observations on chemical reactions apparently very diverse in character It has also given the chemical engineer the power to calculate the conditions for achieving the maximum technical success in the conduct of any chemical manufacture on the large scale. Unfortunately, though the application of thermodynamics has been so successful in the study of chemical equilibrium, it has as yet taught us nothing about the rate at which equilibrium is attained, or, in other words, about the rate of chemical reaction. There seems to be no direct connection between the rate of a reaction and either the heat evolved (change in total energy), or the maximum work of the reaction (change in free energy). Hydrogen has a great affinity for oxygen, and much heat is evolved when they combine, yet a mixture of them can be kept for an indefinite period of time at the ordinary temperature without a trace of combination Nitric oxide is an extremely unstable substance at low temperature; on thermodynamical grounds we should expect that only an infinitesimal amount of it would be in equilibrium with nitrogen and oxygen at the ordinary temperature; yet it is so difficult to decompose by heat that even at 900° C it only decomposes slowly. Ammonia becomes progressively less stable as the temperature is raised. Thermodynamics indicates that in order to obtain high yields, its synthesis from nitrogen and hydrogen should be conducted at as low a temperature as possible. The reaction is, however, so slow that technical manufacture only becomes possible at temperatures so high that the yield of ammonia at atmospheric pressure is extremely small. The ill effects of the high temperature have to be counterbalanced by the use of high pressures. Nearly all gas reactions take place extremely slowly unless the temperature is very high Nearly all, too, take place more quickly in the presence of certain solids called catalysts. The nature of the catalyst to produce the best results varies with the nature of the reaction, and though many theories have been put forward to account for their action, there is no general theory which has been successful in predicting anything—which is the ultimate test of the real value of a theory

Free Energy.—The second law of thermodynamics deals with changes in the free energy of a system A system only possesses "free energy" when it is capable of doing work It is only capable of doing work if it will change spontaneously into another system of greater stability Only an unstable system has free energy A stable system can be changed into an unstable system by the performance of work, or by the transference of free energy from another system The whole of life, and of civilization as we know it, depends on thermodynamic instability, as Boltzmann (1886) put it, the struggle for existence is a struggle for free energy available for work Nearly all manufacturing processes depend essentially on using the free energy stored in coal to convert a useless stable system into a useful unstable system. For instance, the synthetic manufacture of fertilizers depends essentially on the use of a small part of the free energy available when coal is burnt, to convert the stable system nitrogen+water, into the unstable system ammonia+oxygen The ammonia in various forms can be made use of to fertilize plants, *i e*, to increase the free energy in the plant world which the animal world can convert again into useful work The enormous amount of energy which the earth continuously receives from the sun is theoretically almost completely available for useful work, for the energy leaves the sun at a temperature over 8,000° and is finally dissipated into space at a temperature of about 300° Absolute Calculation shows that the energy so received is at least a million times greater than the energy given by the world's power plants But unfortunately we know of no means for making use of anything more than a minute fraction of the sun's energy. A very small part of it is converted into mechanical energy by water power plants, another very small part is used by the plant world to build up "unstable" organic compounds, and thus to supply the free energy available in food. One of the chief tasks of the scientist of the future will be to devise means for converting into useful work, or storing, a greater part of the energy received from the sun The second law shows that this should be possible If he does not succeed the advance, and even the maintenance, of civilization may be impossible when the energy stored in coal through the agency of the plant world in past ages is exhausted.

The Third Law of Thermodynamics.—It has already been pointed out that although the Gibbs–Helmholtz equation enables us to calculate from purely thermal data the change in any equilibrium with the temperature, it does not give any information on the actual value of the equilibrium constant unless this is already known from experimental observations under one set of conditions To obtain the actual value from purely thermal data, it is necessary to integrate the fundamental equation $d\log_e K/dT=U/RT^2$, and integration introduces an unknown integration constant

In 1901 Nernst advanced a method of evaluating this constant, and his theorem is often referred to as the "third law" of thermodynamics, although its universal applicability is still open to some doubt

In Condensed Systems—Nernst postulates that in the case of chemical reactions in *condensed systems, i e.,* reactions in solids or between solids and liquids, not only does A become $=U$ at

absolute zero ($T=0$), as is required by the Gibbs-Helmholtz equation, but that they both reach their final (equal) value at temperatures not far removed from the absolute zero In mathematical language, $dA/dT=dU/dT=0$ when $T=0$ Now dU/dT is equal to the difference between the sum of the molecular heat capacities (C_v) of the reacting substances and of the products. Since it is found by experiment that the specific heats of substances can be expressed with sufficient accuracy by equations of the form $C_v=a+bT+cT^2+$ etc it follows that U can also be expressed in the form

$$U=U_0+\alpha T+\beta T^2+\gamma T^3+ .$$

But if $dU/dT=0$ when $T=0$, it follows that $\alpha=0$, or

$$U=U_0+\beta T^2+\gamma T^3.$$

If this expression for U is substituted in the fundamental equation $A-U=T\ dA/dT$, it follows that

$$A=U_0+aT-\beta T^2-\frac{\gamma}{2}T^3-\text{etc}$$

where a is an unknown constant But if $dA/dT=0$ when $T=0$, as Nernst postulates, a must also be equal to zero, and therefore

$$A=U_0-\beta T^2-\frac{\gamma}{2}T^3-\text{etc}$$

Hence if the heat of reaction, and the specific heats of the substances taking part in the reaction are known, it should be possible to calculate A for any temperature

Consider such a change as the melting point of a solid, or a transition from one modification to another such as the change from rhombic to monoclinic sulphur Then at the temperature when the solid and liquid, or the two forms of solid, co-exist in equilibrium, A, the work obtainable from the change, is zero If we know the heat of the reaction at this temperature (latent heat), and if we know the difference between the specific heats of the two forms over a wide range of temperature, we can express U in the form

$$U=U_0+\beta T^2+\gamma T^3+$$

and therefore T, the temperature where $A=0$ (melting point, or transition point), is given by

$$U_0=\beta T^2+\frac{\gamma}{2}T^3+\cdots$$

Nernst has shown how the transition point of sulphur can be calculated in this way from purely thermal data.

The difficulty of applying the theory to a wide range of such reactions is due to the fact that the all-important knowledge of the variation of specific heats with temperature is still lacking in the majority of cases. only in the case of regularly crystallizing elements do we now know the relation accurately Theory is insufficiently advanced to guide us in the other cases, and accurate experimental work over a great range of temperature is extremely difficult as well as laborious Nevertheless the application of the Nernst theorem to many different types of condensed systems has been so successful, and the theorem itself is supported in so many other indirect ways, that there is little doubt as to its essential truth

In Gas Reactions—It is, however, in its extension to gas reactions that the Nernst theorem has won its most significant successes. If we substitute for U in the van't Hoff equation, the expression

$$U=U_0+\alpha T+\beta T^2+\cdots$$

we get
$$\frac{d\log_e K}{dT}=\frac{U_0}{RT^2}+\frac{\alpha}{RT}+\frac{\beta}{R}+\cdots$$

Integration gives

$$\log_e K=-\frac{U_0}{RT}+\frac{\alpha}{R}\log_e T+\frac{\beta}{R}T\ \cdots+I,$$

where I is an unknown integration constant. Since the vapour pressure (p) of a liquid is similarly connected with the latent heat (λ) by the equation $d\log_e p/dT=\lambda/RT^2$, we can also write

$$\log_e p=-\frac{\lambda_0}{RT}+\frac{\alpha_0}{R}\log_e T+\frac{\beta_0}{R}T+\text{etc.}+i,$$

where i is the unknown integration constant of the vapour pressure curve.

Nernst shows that a consequence of his fundamental theorem is that $I=\Sigma ni$, where n is the number of molecular species taking part in the reaction; that is to say, if the reaction is

$$A+B+C+\text{etc.} = D+E+F+\text{etc.}$$

then $$I=i_A+i_B+i_C+\cdots-i_D-i_E-i_F\ \cdot\text{etc.}$$

This is a most important advance, for it means that it is possible to calculate any equilibrium between gases, provided the heat of the reaction is known, and the vapour pressure curves of the molecular species taking part in the reaction.

In the absence of sufficiently accurate data to make the strict application of the Nernst theorem possible, except in a very small number of cases, Nernst has also developed an approximation formula which is of great practical use It depends on the fact that the *vapour pressure* of most substances can be represented sufficiently accurately by the equation

$$\log_{10}p=-\frac{\lambda_0}{4{\cdot}57T}+1\ 75\log_{10}T-\frac{\beta T}{4\ 57}+C.$$

C, the so-called *conventional chemical constant*, is itself found to be approximately $0{\cdot}14\ \lambda/T_0$, where λ is the latent heat at the boiling point T_0. For most substances which are liquid at the ordinary temperature, $\lambda/T_0=22$ approximately, and therefore $C=3{\cdot}1$ Only a few substances give values for C under 3, mainly they vary between 3 and 3·5

On the basis of this semi-empirical vapour-pressure equation the corresponding formula for gaseous equilibria becomes·

$$\log_{10}K_p=-\frac{Q_p}{4{\cdot}57T}+\Sigma n{\cdot}1{\cdot}75\log_{10}T+\frac{\beta}{4\ 57}T+\Sigma nC$$

which may as a rule be further simplified by omitting the term $\frac{\beta}{4{\cdot}57}T$, thus giving·

$$\log_{10}K_p=-\frac{Q_p}{4{\cdot}57T}+\Sigma n{\cdot}1\ 75\log_{10}T+\Sigma nC.$$

Now it is not pretended that an equation of this form represents actual results with accuracy. Its claim of utility is that it is based generally on correct principles, and that in actual practice it represents with considerable success the effect of temperature on chemical equilibria. A few examples will show how this claim is borne out

(*a*) Consider the reaction:

$$2CO+O_2=2CO_2+136{,}000\text{ calories.}$$

K_p, the equilibrium constant, is $P^2_{CO}\times P_{O_2}/P^2_{CO_2}$, where P_{CO}, etc, represents the partial pressure of CO, etc., in the equilibrium mixture. Q_p, the heat of reaction at constant pressure and room temperature, is 136,000 calories. Σn is the difference between the number of molecules on the left and right hand sides of the chemical equation, *i.e.*, $\Sigma n=1$; ΣnC is twice the chemical constant of CO plus the chemical constant of O_2 minus twice the chemical constant of CO_2, *i.e*,

$$\Sigma nC=2\times3{\cdot}5+2{\cdot}8-2\times3{\cdot}2=3{\cdot}4.$$

$$\therefore\ \log K_p=-\frac{136{,}000}{4{\cdot}57T}+1\ 75\log T+3\ 4.$$

At 2,000° Abs. K_p calculated from this equation is 2×10^{-6} whereas the most recent results indicate that this value is reached at 2,020° Absolute. When CO_2 is half dissociated, there are 0·5 molecules of CO_2, 0·5 of CO, and 0·25 of O_2 present at equilibrium. If the total pressure is 1 atmosphere, the partial pressures of

CO and CO_2 are $\frac{0.5}{1.25}$ atmos., and of O_2, $\frac{0.25}{1.25}$ atmos., therefore, $K_p = 0.2$. The corresponding temperature is calculated from the above equation to be 2,930° Abs., whilst the temperature actually observed is 3,100°.

(*b*) If the reaction brings about no change in the number of molecules, the second term of the equation vanishes, and the third usually becomes very small. For instance

$$2NO = N_2 + O_2 + 43{,}200 \text{ cals}$$

and $$\log K_p = \log \frac{P^2_{NO}}{P_{N_2} \times P_{O_2}} = -\frac{43{,}200}{4.57T} + 1.6 = -\frac{9{,}450}{T} + 1.6.$$

This shows, in accordance with observation, that only at very high temperatures are appreciable quantities of nitric oxide formed from nitrogen and oxygen.

(*c*) If on the other hand, the change in the number of molecules is big, then the first term of the equation may be of little influence. For instance, the probability of a high-boiling paraffin hydrocarbon being formed from hydrogen and carbon can be calculated:

$$nC + (n+1)H_2 = C_nH_{2n+2} + Q \text{ calories}$$

Thomsen's experiments have shown that the heat of formation of such a hydrocarbon from its elements is given approximately by $Q_p = (7n+15)1{,}000$. As the chemical constant of H_2 is 1.6, and of C_nH_{2n+2} about 3.0 we have

$$\log K_p = \log \frac{P^{n+1}_{H_2}}{P_{C_nH_{2n+2}}} = -\frac{1000(7n+15)}{4.57T} + n \times 1.75 \log T + 1.6n - 1.4.$$

Suppose $T = 773°$, *i.e.*, 500° C. Then

$$\log \frac{P^{n+1}_{H_2}}{P_{C_nH_{2n+2}}} = -1.98n - 4.24 + 5.06n + 1.6n - 1.4 = 4.68n - 5.64.$$

If $n = 1$, *i.e.*, if the hydrocarbon formed is methane, CH_4, then

$$\log \frac{P^2_{H_2}}{P_{CH_4}} = -0.96 \quad \text{or} \quad \frac{P^2_{H_2}}{P_{CH_4}} = 0.11$$

from which it can be calculated that if hydrogen is passed over carbon at 500° C, the issuing gas should contain about 70% of methane if equilibrium is reached. Experimental results agree quite well with this. If, however, $n = 7$, *i.e.*, if the hydrocarbon is heptane, C_7H_{16}, which boils at about 100°C., $\log \frac{P^8_{H_2}}{P_{C_7H_{16}}}$ is over 27, or $\frac{P^8_{H_2}}{P_{C_7H_{16}}}$ is over 10^{27}, which means that the amount of heptane formed at atmospheric pressure will be quite negligible. All the higher liquid hydrocarbons, such as occur in natural petroleum oil, are thermodynamically unstable at ordinary temperatures. They tend to pass into carbon and methane, but the velocity of this reaction at ordinary temperatures is very slow. If they are heated, however, they are "cracked"; hydrocarbons of lower boiling point, such as occur in petrol, are formed, and coke and gas are formed at the same time. If the cracking is continued for a long time at atmospheric pressure, the whole liquid forms into coke and gas (mainly methane). But high pressure tends to prevent the formation of gas and coke, and to give therefore a higher yield of "petrol." This is in complete general agreement with the Nernst equation, which enables us to predict approximately the conditions for the best technical success.

The further development of the third law, and its quantitative application to chemical problems depends on the provision of accurate data on the specific heats of substances over a wide range of temperature. The increase in the specific heat of gases as the temperature is raised lacks at present any sound theoretical explanation. The classical kinetic theory of gases does not account for it, and the more recent developments of the quantum theory have hitherto failed to be of assistance. But there can be little doubt that the third law provides in principle a complete explanation of the connection between chemical equilibria and the thermal changes associated with chemical reactions.

(H. T. T.)

THERMODYNAMICS. The name thermodynamics (from Gr. θερμός, hot, δύναμις, power), was originally given to the branch of science dealing with the motive power of heat, or the transformations of heat into mechanical work, or vice versa. A summary of the historical development of thermodynamics from this point of view is included in the article HEAT. Further illustrations relating to heat-engines will be found in the articles GAS-ENGINE, and STEAM-ENGINE. The subject was soon extended to include other applications of the same general principles (1) the conservation of energy, and (2) Carnot's principle of the reversible cycle, which are commonly known as the first and second laws of thermodynamics. The present article is intended to deal mainly with applications of these principles to the relations between the physical properties of a simple substance. Further applications to physical chemistry, dealing with the conditions of equilibrium between different substances, are dealt with in a separate section.

THERMODYNAMICS AND HEAT ENGINES

Definitions of Symbols.—The principal physical properties of the working fluid with which we are concerned in the case of heat-engines are the specific volume V, the intrinsic energy E, the total heat H and the entropy Φ, all of which are measured per unit mass of the substance considered. The laws of thermodynamics require certain general relations between these properties and their derivatives, as affected by additions of heat Q per unit mass, or by variations in the imposed conditions of temperature T and pressure P. It should be observed that in all these relations P is the absolute pressure and not the gauge-pressure, and that T is measured on the absolute scale, as defined by Carnot's principle which differs very little from absolute temperature on the scale of a gas thermometer. Temperature measured on the same scale from 0° C is denoted by t, so that $T = t + 273.1°$. The total heat H is defined as $E + aPV$ in thermal units, including the equivalent aPV of the work PV done by the pressure P on the volume V of unit mass. The entropy Φ of a quantity of heat Q supplied at a temperature T is defined as Q/T. The entropy of a substance per unit mass is the property which remains constant in adiabatic expansion, when no heat is supplied by friction or otherwise, as will be more fully explained in a later section, in connection with the second law of thermodynamics.

Applications of the First Law.—The intrinsic energy E denotes the quantity of energy existing in unit mass of the substance in any given state, which may in general be specified by its volume V and temperature T. We have no means of measuring the total quantity of energy contained in any body in a given state, but it suffices to be able to measure changes of E from any convenient state E_o selected as the zero. Any such change from E_o to E may be measured by observing the quantity of heat Q required to produce the change and the work W done by the substance per unit mass in the process. Assuming that no energy is lost, the application of the first law to this case gives the obvious relation

$$Q = E - E_o + W/J. \tag{1}$$

In any equation of this kind it is tacitly understood that all the terms are reckoned per unit mass of the substance, and are expressed in terms of the same units, either units of work or units of heat as desired. The general practice in dealing with heat-engines is to measure Q, E, and H in thermal units per unit mass, and to reduce W to thermal units by dividing by the appropriate value of the mechanical equivalent J. In nearly all cases W represents work done by expansion $V - V_o$ against a uniform pressure P, in which case $W = P(V - V_o)$, if P remains constant during the expansion, and equation (1) takes the form

$$Q = E - E_o + aP(V - V) = H - H_o \text{ at const. } P, \tag{2}$$

where the total heat H is defined as $E + aPV$, and a is the factor required for reducing PV to heat units per unit mass. The factor

required for this purpose in practice is seldom $1/J$, because pressure-gauges are never graduated in lb./sq.ft. or kg./sq.m., but often in arbitrary units such as inches of mercury.

Specific Heats.—If the heat Q is added at constant volume, $V=V_o$, and $W=0$, so that $Q=E-E_o$. If $T-T_o$ is the rise of temperature, we observe that the increase of E per degree at constant volume V_o is equal to $Q/(T-T_o)$, which is by definition the specific heat S at constant volume. Similarly $(H-H_o)/(T-T_o)$ from (2) is equal to the specific heat S at constant pressure. Thus the values of E along a line of constant volume on any diagram may be found from observations of the specific heat s at constant volume. Similarly values of H along a line of constant pressure may be deduced from observations of the specific heat S at constant P.

Thus $H-H_o=S(T-T_o)$ at const. P,

and $\quad E-E_o=s(T-T_o)$ at const. V $\qquad$ (3)

These simple relations between H and S, and E and s, are exact for all substances at all temperatures in consequence of the definition of H, and are often very useful. But the specific heats S and s may vary widely with temperature and pressure, in which case it is usually better to measure H or E directly, in place of trying to deduce them from empirical formulae for S or s. In the case of solids or liquids, since V is small and varies little with T, the variation of E at constant *pressure*, such as atmospheric, does not differ appreciably from that of H. But the variation of H at *constant volume* may greatly exceed that of E under the same condition on account of the high pressures developed. In practice it is usually preferable to measure the value of H and deduce that of E, if required, by subtracting aPV.

Application to Gases.—In the case of ideal gases obeying the law $aPV=RT$, it follows directly from the general relations (3) that the difference $S-s$ is constant and equal to R. It will be shown later that the specific heats of such gases cannot vary with *pressure*, though they may vary considerably with *temperature*, while the difference $S-s$ remains constant, as in the case of hydrogen. (*See* HEAT.) On the other hand, vapours, like steam, though they usually approximate closely to the law $aPV=RT$ at low pressures, show large deviations from the gas-laws at high pressures near saturation, and the value of S shows a wide range of variation with *pressure*, especially near the critical point. Fortunately these variations can be deduced from the thermodynamical relations given in a later section of this article.

Cycle or Cyclical Process.—The application of the first law, as expressed in (1), to the cycle of a steam-engine, in which the working fluid is restored to its initial state of water at each repetition of the cycle, is fully considered in the articles already referred to. Briefly stated, if $E=E_o$ at the conclusion of the cycle Σ_o, it follows from (1) that the algebraic sum ΣQ of all the quantities of heat Q received and rejected by the working substance during the cycle must be equal to the net balance of work done by the engine per cycle, work done *by* the fluid in expansion being reckoned positive, and work done *on* the fluid in compression being reckoned negative. With this understanding the formula for the cycle may be expressed as follows,

$$\Sigma Q=\Sigma W=\int PdV \qquad (4)$$

In an ideal reversible engine, in which no heat is lost and no work is wasted in friction, the area of the cycle on the PV diagram, expressed by the integral of PdV taken round the cycle, will represent the maximum work obtainable from the cycle considered. In any actual engine some of the heat received by the working fluid is lost before it has contributed its full quota of work, and some of the work done is reconverted into heat by internal friction and is rejected in the form of heat. If the properties of the working fluid are known, such losses may be estimated in the reciprocating engine by comparing the ideal diagram, as calculated, with the actual diagram as observed with the indicator. (*See* STEAM-ENGINE.) In the case of a turbine, to which the indicator method is inapplicable, it is necessary to use a different kind of diagram, or the ideal output may be calculated from the properties of the working fluid, and compared with that actually realised.

Frictionless Adiabatic Expansion.—The term "adiabatic" implies that there is no gain or loss of heat by the working fluid. Putting $Q=O$ in (1) we see that in this case $E-E_o$ must be equal to $-W/J$, or the intrinsic energy of the working fluid is *diminished* by an amount equivalent to the work done. If no work is wasted in friction, this represents the most efficient method of conversion of heat into work, which is the ultimate aim of every heat-engine. To calculate the work done from the integral of PdV under this condition, it is necessary to know the form of the expansion curve on the PV diagram, or the adiabatic equation representing the relation between P and V for the working fluid employed, which requires an appeal to experiment. Watt made the first experiments of this kind with his indicator, but found the expansion curve for a slow speed engine using wet steam to be approximately $PV=$ constant, the same as Boyle's law for the expansion of a gas at constant temperature, whereas the fall of pressure in adiabatic expansion should have been more rapid than that given by Boyle's law owing to the fall of temperature. Watt was well aware that this anomaly was due to partial condensation of the steam on admission by the cool walls of the cylinder, followed by re-evaporation towards the end of the stroke, which made the conditions far from adiabatic. Laplace subsequently showed (*see* HEAT) that the rate of drop of pressure dP/dV in the adiabatic expansion of a *gas* must exceed that for the same state at constant temperature, in the ratio, $S/s=\gamma$, of the specific heats. Assuming Boyle's law for a gas at constant temperature, and $\gamma=$ constant in adiabatic expansion, it followed that the adiabatic equation must be of the form, $PV^\gamma=$ constant for a gas.

The adiabatic equation of Laplace and Poisson for a gas, was established long before the first law of thermodynamics was formulated, and has proved to be the most convenient type of equation for the purpose. But with the assistance of the laws of thermodynamics, the scope of the adiabatic equation in this form may be considerably extended. Thus with the assistance of the first law, in the form in which it is usually employed for mathematical purposes, namely

$$dQ=dE+aPdV=dH-aVdP \qquad (5)$$

the adiabatic equation, $PV^\gamma=$ constant, may be shown to apply generally to any kind of substance, not necessarily a perfect gas, for which the change of intrinsic energy in any transformation is proportional to that of aPV, or more generally that it will be of the form $P(V-b)^\gamma=$ constant, provided that the expression for the intrinsic energy E satisfies the condition,

$$E-B=naP(V-b) \qquad (6)$$

in which B, b, and n are constants depending on the substance, and $\gamma=1+1/n$.

To prove this relation, we put $dQ=0$ in (5) as the general condition for the adiabatic, and equate dE as obtained from (6) to $-aPdV$, which gives,

$$an(V-b)dP+a(n+1)PdV=0. \qquad (7)$$

Dividing by $aP(V-b)$ and integrating we obtain

$$n \log P+(n+1)\log(V-b)=\text{constant} \qquad (8)$$

which when put in the exponential form becomes

$$P(V-b)^{n+1/n}=\text{constant} \qquad (9)$$

It will be observed that the value of the index γ is *constant*, and is not necessarily equal to the ratio of the specific heats, which may vary widely with pressure. This is fortunate, because an equation of this type is of little practical use if the index is variable.

With the assistance of the second law of thermodynamics in addition to (5) and (6), it will be shown in a later section that the same adiabatic (9) may be put in either of the equivalent forms

$$P/T^{n+1}=\text{constant}=k_1 \text{ or } (V-b)T^n=\text{constant}=k_2 \qquad (10)$$

and that $P(V-b)/T=k_1k_2=$ constant, along an adiabatic, though it is not necessarily constant under other conditions.

Experimental Verification of the Adiabatic.—The most direct way of testing the adiabatic equation is to use a cylinder containing a constant charge of gas or vapour which is alternately compressed and expanded by a reciprocating piston. Indicator cards give fairly accurate values of the actual volume and pressure, if the clearance is carefully measured, the pressure scale calibrated, and everything in perfect adjustment. But in working

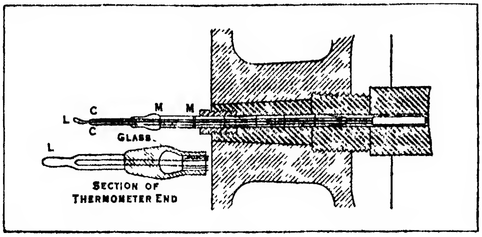

FIG. 1

over large ranges of pressure, as is necessary for a satisfactory verification, there are formidable difficulties due to the wide variation of heat exchanges between the charge and the walls of the cylinder at different points of the stroke. These effects are further complicated by accidental leakage past the piston, and, in the case of steam, by the risk of condensation, both of which affect V indirectly by reducing the apparent mass of the charge. The most complete method of eliminating these uncertain sources of error, which profoundly affect the uniformity of V throughout the cylinder, is to observe, instead of the relation between P and V, the relation between T and P, as given by the adiabatic equation in the form (10), deduced from the second law In this case the temperature observed in the middle of the cylinder will be practically unaffected by the action of the walls, and is determined solely by the *actual* pressure as observed with the indicator. We are no longer concerned with the *theoretical* pressure, corresponding to the compression ratio by volume, which might be realized in the absence of condensation or leakage or heat-loss to the walls These effects will still reduce the observed pressure below the theoretical value, but will not affect the relation between pressure and temperature. The success of the thermometric method depends on the construction of a thermometer sufficiently sensitive to follow the rapid variations of temperature without appreciable lag, and on obtaining simultaneous readings of the relative values of the pressure with the same order of accuracy at the maximum and minimum points of the cycle. It is easy to cover the range of temperature with a single thermometer. but, the pressure range being upwards of 10/1, it is necessary to use a separate indicator with a light spring for the low pressures. Applied in this manner the method is particularly suited to give the best average value of the index over large ranges of pressure and temperature. The procedure may be varied when it is desired to obtain the value of the index at some particular point of the scale, *e g.*, at high or low temperatures

The annexed figure 1 shows one of the thermometers employed for this purpose, mounted on the piston of a steam-engine for observing the adiabatic relation between P and T for dry steam The sensitive portion of the thermometer consisted of a differential loop L of fine platinum wire a thousandth of an inch in diameter and 1 inch in length. The fine wire was connected to thick platinum leads, insulated by being fused through a glass tube MM held in a gland in the centre of the piston. The platinum leads in the glass tube were connected to insulated copper leads, which were carried out to the measuring apparatus through a hole 2 ft. long bored through the piston rod. Since the ends of the fine wire, where it is attached to the thick platinum leads, cannot follow the rapid variations of temperature of the steam, it is necessary with this type of thermometer to compensate these end-effects by connecting a short loop of the same fine wire to the ends of the compensating leads CC. The quantity measured being the difference of resistance of the long and short loops, all such end-effects are automatically eliminated. Readings of temperature were taken with the aid of a periodic contact (mounted on the revolving shaft) which could be adjusted, while the engine was running, in such a way as to close the circuit of the galvanometer at any desired point of the stroke It was found possible to read the temperature to one or two tenths of 1° C at the maximum and minimum points, with the engine running at 100 rev./min and a range of temperature of about 300° C between maximum and minimum. Readings taken at intermediate points, where the temperature was changing at the rate of more than 500° C per second, showed very good agreement, but could not be utilised in the calculation because the simultaneous values of the pressure could not be located with sufficient accuracy on the steep part of the indicator curve, whereas the maxima and minima could be measured with the greatest precision. The ports of the cylinder used in these experiments were caulked with lead to prevent leakage, and the cylinder was heated by steam in the jackets and steam-chest to minimize condensation. The flywheel was belted to an electric motor and driven at a steady speed by a large storage battery. The observations covered a range of temperature from 100° to 420° C, but could not be extended beyond 150 lb pressure by this method, owing to deficient strength of the engine and driving gear. The results obtained with several different thermometers and indicators, showed that the adiabatic index for steam must be very nearly constant over this range of pressure and temperature with a value given by $n+1=13/3$ in (10), or $\gamma=1{\cdot}300$ in the relation (9) between P and V. Recent observations on the total heat H up to 4,000 lb. pressure, have shown that the same relation holds for dry steam with remarkable accuracy in the critical region, in spite of enormous variations in the ratio of the specific heats. The importance of this result in practice lies in the fact that it gives a very simple expression (6) for E or H in terms of P and V, or for V in terms of H and P, in addition to giving the simplest possible expressions for the work done in adiabatic expansion, or for the discharge through a nozzle, the utility of which can hardly be exaggerated in practical thermodynamics Similar relations, but with $\gamma=1{\cdot}40$ or $n=2{\cdot}5$, have long been applied to the case of atmospheric air, which forms the chief constituent of the working fluid in the internal combustion engine But in the case of air the application is much more simple and obvious, because air obeys the gas equation $aPV=RT$ very closely, and its specific heats vary very little with pressure under ordinary conditions.

The Energy Equation in Steady Flow.—The flow of a fluid through a pipe or any closed apparatus, is said to be "steady" when the mass M per second passing any cross-section X is the same at every point, and remains constant during the flow This implies that the fluid is supplied at a steady rate by some external agent (*e g.*, a pump or boiler) at a constant pressure and temperature, in which case the whole apparatus traversed by the fluid will soon settle down into a steady state in which the values of P, V, and T remain constant at each point, though they will not be the same at different points, if the section X varies from point to point, or if the fluid receives heat or does work at a steady rate during its passage. It follows from the law of conservation of mass that, when the mass-flow M is constant at every point, the velocity U of the fluid at any section X is given in terms of V by the relation

$$U=kMV/X \qquad (11)$$

where k is a constant depending on the units employed

A second relation follows from the law of conservation of energy, since the energy existing in any section must remain constant when the conditions are steady. The total energy carried into any section by the fluid per unit mass in thermal units will consist of its intrinsic energy E', together with the equivalent $aP'V'$ of the work done by the pump, and with the kinetic energy of flow, $K'=U^2/2Jg$, reduced to thermal units by the factor $1/Jg$. Thus the total energy carried in by the fluid may be represented briefly by $H'+K'$. Similarly the total energy carried out of the same section by the fluid may be represented by

$H''+K''$. But with the energy carried out we must include the equivalent W/J of any work done by the apparatus, and any heat Q lost by radiation or convection, both measured per unit mass of the fluid passing through Collecting the terms, the general equation may be written

$$H'-H''=K''-K'+W/J+Q \qquad (12)$$

The steam-turbine may be taken as a typical example. $H'-H''$ represents the drop of total heat of the fluid, or more briefly

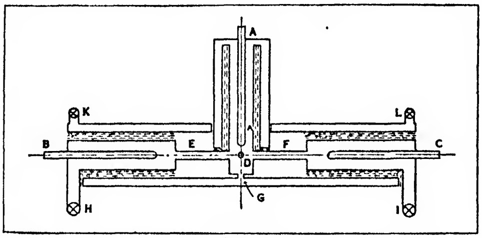

FIG. 2

the 'Heat-drop,' between the inflow and outflow of any section In an efficient machine, this heat-drop is very nearly equivalent to the external work W done by the steam on the revolving blades. The external heat-loss Q is a small percentage of the whole. The kinetic energy K'' of the steam leaving the section usually exceeds K', that of the steam entering and $K''-K'$ represents a similar percentage loss The greater part of the loss in a turbine is that due to internal friction, by which part of the available kinetic energy is reconverted into heat. This part of the loss is included in the total heat H'' carried out by the steam. If there were no friction or heat-loss, the drop of total heat, representing heat converted into kinetic energy or work, would be that obtainable in frictionless adiabatic expansion between the same limits of pressure, which may be found from the tables and compared with the actual performance to estimate the efficiency. The method of doing this will be explained later, when some of the simpler applications of equation (12) have been illustrated.

The Throttling Method.—The function of a throttle, or reducing-valve, is to regulate the flow, or change the state of the fluid, by lowering the pressure without altering the total heat The throttle, having no moving parts, cannot do any external work, so that $W=0$ in equation (12) In this case, most of the kinetic energy is reconverted into heat by friction, so that K'' can be made nearly equal to K' under favourable conditions. The equation then reduces to the form

$$H'=H''+Q \qquad (13)$$

The chief use of the equation in this form is to find the value of the total heat H' at a high pressure by throttling to a lower pressure, such as atmospheric, and observing the temperature T''. The total heat H'' at the lower temperature and pressure may be regarded as known by equation (3) in terms of the specific heat S. Thus the required value of H' at T' and P' is given by (13) if the heat-loss Q can be determined. The best way of doing this is to employ a differential calorimeter as shown in fig. 2. The high pressure steam enters the centre pocket at the back and circulates round the thermometer tube (A) for measuring the initial temperature The initial pressure is measured at the same point through the connection (D) to the high pressure gauge. The main current then divides right and left through the throttle tubes (E) and (F) to the side pockets (B) and (C) where the temperature of the throttled steam is measured. These pockets are precisely similar, and are lagged and jacketed with throttled steam in order to reduce heat-loss, which would otherwise be rather large at high temperatures. The throttle tubes are fitted with a progressive series of throttles and baffles, designed to give maximum friction and reduce the kinetic energy to a negligible quantity. Using single and double dashes to distinguish the two sides, the flows M' and M'' on either side, as defined above can be adjusted in any desired ratio. The *rate* of heat-loss $M'Q'$ per second will evidently be nearly equal to the rate of heat-loss $M''Q''$ from the other side. Hence Q' and Q'' (per unit mass) will be inversely as the flows, which are condensed and measured separately. For instance, if $M'=2M''$, we have $Q''=2Q'$, and $Q'=H'-H''$, by taking the difference between the two equations

$$H'+Q'=H_o=H''+Q'' \qquad (14)$$

where H_o represents the total heat in the centre pocket. Whence $H_o=2H'-H''$, both of which are known from the observed temperatures t' and t''. Since S is nearly constant for steam at atmospheric pressure, it usually suffices to correct the observed temperature t' for heat-loss by adding $(t'-t'')\ M''/(M'-M'')$, as in the following example. Starting with steam at 3,805 lb pressure and 426·6° C, the observed temperatures on either side after throttling to 16 lb. were $t'=120{\cdot}3°$ C and $t''=114{\cdot}1°$ C, the ratio $M''/(M'-M'')$ being 0·97. The correction to t' for heat-loss is $0{\cdot}97\times6{\cdot}2°=6{\cdot}0°$, giving 126·3° C for the corrected temperature, at which $H_o=652\ 4$ cal C, as given in the tables at 16 lb This method is one of the simplest for measuring H at high pressures and temperatures, but cannot be applied if H is less than 640 cal, because the throttled steam would be wet Thus in measuring H at the critical point, 374° C, and 3,222 lb, where its value is only 554 4 cal. it is necessary to use the jacketed condenser method as described in the article CALORIMETRY This method is rather more difficult, but has the advantage of applying equally to the case of water

Discharge Through a Nozzle.—The function of a nozzle in a turbine is to convert as much as possible of the total heat of the steam into kinetic energy for turning the wheels For this reason the nozzle is formed with a bell-mouth on the high pressure side tapering smoothly to a nearly parallel throat, so as to produce a uniform jet of high velocity with the least possible friction or turbulence. In this respect the nozzle is the opposite of the throttle which reconverts as much as possible of the kinetic energy into heat, leaving the total heat practically unaltered In one respect it is like the throttle, in that it has no moving parts and does no external work in itself, so that $W=0$ in equation (12), when applied to either nozzle or throttle The heat-loss Q in the case of a nozzle is also very small compared with the heat-flow, which is usually large owing to the high velocity of flow. Neglecting W and Q on this account, the heat-drop is the exact equivalent of the kinetic energy generated, thus equation (12) becomes

$$H_1-H_2=K_2-K_1=(U_2^2-U_1^2)/2Jg, \qquad (15)$$

in which the constant Jg is required for reducing $U^2/2$ to heat units. It may be observed that equation (15) remains true if any proportion of the kinetic energy generated is reconverted into heat by friction, since this has the effect of increasing H_2 exactly as much as it reduces K_2 As a rule the initial velocity is small and K_1 is almost negligible in comparison with K_2. The velocity generated may then be calculated from the heat-drop by the formula

$$U_2=(2Jg)^{\frac{1}{2}}\ (H_1-H_2)^{\frac{1}{2}} \qquad (16)$$

If H is taken in calories C and U in feet per sec., the value of the constant is 300·2, or a heat-drop of 1 cal. C will correspond to a velocity of 300 ft./sec.; or 100 cal. to 3,002 ft./sec. A velocity of 100 ft./sec., or 70 miles per hour, though not unimportant in meteorology, may often be neglected in dealing with turbines, as it corresponds to only $\frac{1}{9}$th of a calorie C. Other conditions being equal, the heat-drop and velocity will evidently be greatest in the absence of friction, or in frictionless adiabatic expansion as defined by putting $dQ=0$ in equation (5). This gives the condition $dH=aVdP$ for finding the heat-drop by integrating $aVdP$ along the adiabatic (9) between the given limits of pressure P_1 to P_2. Neglecting b, this reduces to the simple form,

$$H_1-H_2=(H_1-B)(1-T_2/T_1) \qquad (17)$$

where $T_2/T_1=(P_2/P_1)^{\frac{3}{13}}$, for steam by equation (10) with $n+1=13/3$.

Having found the heat-drop, which is preferably obtained from the Tables, the velocity U_2 follows from (15), or from (16) if U_1 is small. The discharge M is easily obtained from (11) in terms of the area of the throat X, and the volume V_2 at the same point. The latter is most easily obtained from H and P by the general relation (6), which may be put in the form,

$$V=(H-B)/a(n+1)P=2\cdot2436(H-B)/P. \qquad (18)$$

Maximum Discharge.—It results from the form of these equations that for any given nozzle or throat area X, for a given initial state of the steam as defined by P_o and V_o, the discharge M will at first increase as the final pressure P is lowered, but will ultimately reach a very definite maximum, when $P/P_o=0\cdot546$ in the case of steam Differentiating (11) to find the condition under which M is a maximum, we have $d(U/V)=0$, or $dU/dV=U/V$. Putting (15) in the form $U^2-U_o^2=2Jg(H_o-H_o)$, differentiating with regard to V, and remembering that U_o and H_o are constant, we obtain

$$-Jg(dH/dV)=U(dU/dV)=U^2/V. \qquad (19)$$

Since by (5) $dH/dV=aV(dP/dV)$ in adiabatic expansion, this may be written,

$$-aJg(dP/dV)=(U/V)^2=(kM/X)^2 \qquad (20)$$

giving the discharge M/X per unit area of throat in terms of dP/dV in the throat. Since equation (20) for $(U/V)^2$ in terms of dP/dV is the general expression for the velocity of sound U in any fluid, we infer that, when M/X is a maximum, the exit velocity of the fluid relative to the throat must be equal to the velocity of sound in the same fluid under the same conditions Thus no drop of pressure beyond the throat could travel back fast enough through the fluid to affect its state in the throat or increase the discharge In the case of any fluid like steam, having the adiabatic equation (9), $dP/dV=-\gamma P/(V-b)$, which when substituted in (20) gives the discharge in terms of P and V in the throat. To find a numerical formula for the maximum discharge in the case of steam (for which $\gamma=1\cdot3$) in terms of the *initial* conditions, P_o, V_o, we have the approximate relations (omitting b, which is very small), which follow from (20),

$$(H_o-H)/(H_o-B)=(\gamma-1)/(\gamma+1)=3/23 \qquad (21)$$

$$P/P_o=0\cdot5457,\ V/V_o=1\cdot5934 \qquad (22)$$

which give for the discharge M/X in lb. per sec. per sq in. of throat ($k=144$),

$$M/X=U/144V=0\cdot3155\ (P_o/V_o)^{1/2} \qquad (23)$$

when P is in lb per sq in., U in ft/sec. and V in cu ft. per lb. The correction for b is less than $\frac{1}{20}$ of 1 per cent when $P_o=300$ lb.

Applications of Carnot's Principle.—The whole science of thermodynamics may be said to date from the establishment by Sadi Carnot (1824) of the principle limiting the amount of work obtainable from heat under given conditions The reasoning by which Carnot established his principle is outlined in the article HEAT, and is justly regarded as one of the most remarkable triumphs of the deductive method, but the experimental data available at the time were far too scanty and inaccurate to supply conclusive proof. With the advance of experimental methods Carnot's predictions have been abundantly verified in every conceivable instance, and have formed the basis of the development of all kinds of heat-engines in theory and practice. The important applications to heat-engines are discussed elsewhere in their proper place. We are here concerned chiefly with the applications of the principle to the thermodynamical relations between the various properties of any substance, and to the conditions which determine the possible states of equilibrium. Carnot in applying his principle to such cases put it in the following form as being most convenient for the purpose. If a quantity of heat Q is supplied to any substance at a constant temperature t, the work dW obtainable from Q by an ideal reversible engine working in a cycle of range dt must be proportional to Qdt multiplied by some function of the temperature, $F't$, which must be the same for all substances. Putting this statement in the form of an equation, we find

$$dW/dt=QF't, \qquad (24)$$

as given by Carnot, and applied by him to the following simple cases:

Clapeyron's Equation—In the vaporisation of unit mass of steam in a boiler, the whole work of expansion W along the isothermal at constant pressure and temperature, would evidently be equal to $p(V-v)$, the product of the vapour-pressure p by the increase of volume from that of water v to that of steam V. Thus the work dW/dt obtainable in a cycle of range dt would be $(V-v)dp/dt$, where dp/dt is the rate of increase of the steam-pressure per degree rise of temperature The heat Q absorbed in the vaporisation of unit mass is the latent heat L Substituting these symbols in (24) we obtain the result commonly known as Clapeyron's equation,

$$(V-v)dp/dt=LF't, \qquad (25)$$

which evidently represents the condition of equilibrium between liquid and vapour at any temperature, and is applicable to any other substance with the same value of $F't$ at the same temperature, but with different values of L, V, and p, depending on the properties of the substance considered. Carnot employed this relation for calculating the value of his function $F't$ at 100° C from the properties of steam, which were roughly known at this temperature. Taking $L=540$ cal. $dp/dt=27\cdot2$ mm. of mercury, or 370 kg/sq metre, and $V-v=1\ 670$ cb m/kg, we find $F't=1\cdot135$ kilogram metres per kilocalorie for the work obtainable in a cycle of 1° range at 100° C. We may remark in passing that the value found is equal to 427/373, being the mechanical equivalent of the kilocalorie in kgm divided by the absolute temperature This implies that the whole of the heat could be converted into work if the range of the cycle were extended to the absolute zero with the same rate of production of work per degree fall But Carnot, who had at that time no knowledge of the value of the mechanical equivalent, naturally failed to notice this remarkable coincidence, though the result he obtained for $F't$ was correct

Lowering of the Freezing Point of Ice by Pressure.—The application of Carnot's equation (25) to the rate of increase of vapour-pressure dp/dt with temperature, or to the rise of the boiling-point dt/dp with pressure (which are merely different ways of expressing the same property of the substance) is easily made in any case in which the latent heat L and volume V of the vapour are known, and affords in fact one of the most direct methods of verifying Carnot's principle by experiment A more dramatic verification was that made by James Thomson (1851), who observed that equation (25) must apply just as exactly to the equilibrium between liquid and solid at the freezing-point, as to that between liquid and vapour at the boiling-point. In the case of solid and liquid, L is the latent heat of *fusion*, and $V-v$ is the increase of volume in melting, which is positive for a substance like wax which expands in melting, but negative for a substance like water which expands on freezing Thus in the case of wax, the sign of dt/dp should be positive, or the melting point should be raised by pressure (as is always the case for the boiling-point), whereas in the case of water the sign should be negative, or the freezing-point should be lowered by pressure. Taking the known values of L and $V-v$ for water and ice, he predicted that the freezing-point of water should be lowered 0·0075° C per atmosphere of pressure, a result which was immediately verified by his brother, Lord Kelvin, and materially assisted in the final establishment of the second law of thermodynamics.

Application to Gases, Absolute Scale of T.—The application of Carnot's equation (24) to the case of a gas obeying the law $PV=RT$, is equally simple. The whole work W done in isothermal expansion, is represented by the analytical expression $RT\ ln\ r$, where $ln\,r$ denotes the natural logarithm of the ratio of expansion. It immediately follows, as Carnot remarks, that $dW/dt=Rlnr$, or is simply equal to W/T. Thus equation (24) reduces to the form,

$$W/T=Q\ F't. \qquad (26)$$

Carnot deduced from this relation that the ratio W/Q of the work done to the heat absorbed in isothermal expansion must be the same for all gases at the same temperature, and that if equal volumes of different gases were taken at the same temperature

and pressure (or masses proportional to the molecular weights) the heat Q absorbed in isothermal expansion must be the same for all gases under similar conditions since the work W was the same for all It followed as a special case that the *difference* of the specific heats at constant pressure and volume, being the heat absorbed in an isothermal expansion equal to V/T, must be the same for equal volumes of all gases His endeavours to extract a value of $F't$ from this relation gave results similar to those obtained from steam and other vapours, but failed to give a decisive conclusion owing to the uncertainty of the ratios of the specific heats as deduced from the velocity of sound. At a later date when Joule (1845) proved by direct experiment that the heat absorbed by a gas in isothermal expansion was approximately *equivalent* to the work done, it became evident, by substituting $W=JQ$ in equation (26) that the value of $F't$ must be nearly equal to J/T for all substances But since according to Regnault's experiments (1847) the temperature scales of actual gases differed quite appreciably, different gases would give different values of T at the same temperature, and it was impossible to say which should be selected The essential point of Carnot's principle being that the value of $F't$ was *the same* for all substances at the same temperature, the most logical method was that proposed by Kelvin, to define absolute temperature T as being proportional to the reciprocal of Carnot's function Exact consistency with Carnot's principle and with the law of conservation of energy could thus be secured, while leaving the deviation of the scale of any particular gas from the absolute scale thus defined to be determined by experiment in each case

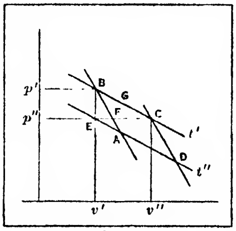

FIG 3

Carnot Cycle of Finite Range—If we substitute J/T for $F't$ in Carnot's equation (24) in accordance with the definition of absolute temperature T, and also write $W=JQ$ as required by the first law, the equation reduces to the form $dQ/dT=Q/T$, which tacitly involves the law of conservation of energy in addition to the adoption of Carnot's principle for the definition of the scale of temperature The relation in this form implies that, if the range of the cycle is extended to any lower temperature, the ratio Q/T will remain constant, and the heat converted into work will increase in direct proportion to the range of temperature, since the constant ratio Q/T is equal to dQ/dT representing the heat converted into work per degree fall Thus the formula for a Carnot cycle of finite range, in which a quantity of heat Q' is supplied to the working substance at T', and a quantity Q'' is rejected at T'', with the conversion of heat $Q'-Q''$ into work W, reduces to the simplest possible form, namely,

$$W/(T'-T'')=J(Q'-Q'')/(T'-T'')=JQ'/T'=JQ''/T'', \quad (27)$$

in which the reduction factor J may be omitted if Q is expressed in work units

Entropy—The quantity Q/T which remains constant in a Carnot cycle of any range bounded by two adiabatics, is called the entropy of the heat Q supplied at a temperature T According to (27) the entropy of the heat supplied at T', is equal to the entropy of the heat rejected at T''. The entropy difference between any two adiabatics is constant, or the adiabatics are lines of constant entropy, and are often called isentropics The thermal equivalent of the work done in any Carnot cycle is the product of the entropy supplied, namely Q'/T', by the range of temperature $T'-T''$. This relation is frequently the most convenient for calculating the work obtainable, not only in a Carnot cycle, but also in a cycle of any form

Clapeyron's Relations.—Clapeyron (1834) observed that Carnot's principle, as represented by equation (24), implied the existence of certain general relations between the quantity of heat absorbed in isothermal expansion and the pressure and expansion coefficients of the working substance He employed the indicator diagram, as illustrated in fig. 3, for the deduction of these relations by a method equivalent to that employed by Maxwell, *Theory of Heat* (1870). The coordinates of the point B are the pressure p', and the volume v' of unit mass of the substance at a temperature t'. Let the substance expand from B to C along the isothermal at t' absorbing a small quantity of heat dQ, while its volume increases from v' to v'', and its pressure diminishes from p' to p''. Draw the line of constant volume v' through B intersecting the line of constant pressure p'' through C in the point E Through E draw the isothermal EAD at the temperature t''. Complete the Carnot cycle by drawing the adiabatics BA and CD through B and C In the limit, when the difference of temperature $t'-t''$ is small, it may be represented by dt as in Carnot's equation (24), and the form of the cycle $ABCD$ will become a parallelogram as indicated in the figure. The area $ABCD$ represents the work dW done in the elementary cycle, and is equal to that of the rectangle $BE\times EC$, or to $(p'-p'')(v''-v')$. Making these substitutions in Carnot's equation (24), we obtain the general relation,

$$(p'-p'')(v''-v')/(t'-t'')=F't\times dQ \quad (28)$$

In order to interpret this relation in terms of the pressure coefficient at constant volume, or the expansion coefficient at constant pressure, as may be desired, we may in the first place transfer $v''-v'$ to the right hand side of the equation We then observe that $p'-p''$ is the increase of pressure BE at constant volume corresponding to the increase of temperature $t'-t''$, so that the ratio represents the familiar pressure-coefficient at constant volume, denoted by $(dp/dt)_v$ in the usual notation of partial differential coefficients Similarly $dQ/(v''-v')$, being the ratio of the heat absorbed at constant temperature to the corresponding increase of volume, may be denoted by $(dQ/dv)_t$ in the same notation If we also substitute J/T for $F't$ in accordance with the definition of absolute temperature, we obtain,

$$T(dp/dt)_v=J(dQ/dv)_t \quad (29)$$

which is often called the first thermodynamical relation, and was in fact employed by Kelvin as a general expression for Carnot's principle in his first exposition of the equations of thermodynamics (1851), except that he retained the symbol μ for $F't$, following Clapeyron, in place of substituting J/T, as in (29), according to modern practice

Pressure and Expansion Coefficients—The utility of a relation of this kind lies in the fact that small quantities of heat absorbed in expansion are very difficult to measure, but can usually be calculated with the aid of relations like (29) in terms of other coefficients, such as the pressure coefficient Many examples of this will be given later If the relation (29) itself is not directly applicable, it can usually be transformed by purely mathematical relations between the various coefficients into a different shape which is more convenient for the purpose required For instance the pressure coefficient $(dp/dt)_v$ is seldom directly measurable in the case of a solid or a liquid, owing to the difficulty of keeping the volume constant while the temperature is being raised. The difficulty of measuring the pressure-coefficient may be avoided by using the familiar relation,

$$(dp/dt)_v=-(dp/dv)_t(dv/dt)_p \quad (30)$$

giving the required value in terms of the isothermal elasticity and the coefficient of expansion at constant pressure, both of which can be measured. Relation (30) is one of the commonest examples in practice of the general relation between the partial differential coefficients of any three quantities, such as x, y, z, connected by a single equation, such that any one of the three may be regarded as a function of the other two. It is most easily remembered in the cyclical form,

$$(dx/dy)_z(dy/dz)_x(dz/dx)_y=-1. \quad (31)$$

from which any required relation of this type such as (30) may be written down by replacing p, v, t, by x, y, z, or *vice versa*. But as relations of this type are usually required in the form (30), it may be as well to explain how they are deduced from first principles. The volume v of unit mass of any substance depends on the temperature t and the pressure p either of which may vary independently of the other. Any expansion due to change

of temperature alone, is found by multiplying the rise of temperature dt by the expansion per degree at constant pressure, represented by the coefficient $(dv/dt)_p$. Similarly any change of volume due to increase of pressure alone, is given by the product of the increase of pressure dp by the isothermal compressibility $(dv/dp)_t$. In the general case, when both p and t change, the whole expansion dv is the sum of the two independent effects,

$$dv = (dv/dt)_p dt + (dv/dp)_t dp. \quad (32)$$

Similar formulae apply to all other properties of the substance depending on p and t and are frequently required in thermodynamics In the case of the volume v, it is immediately obvious from (32) that, if the compression due to increase of pressure dp is equal to the expansion due to increase of temperature dt, the volume will remain constant, or $dv=0$. The ratio of dp to dt at constant volume, or the required coefficient $(dp/dt)_v$, is obtained in terms of the other two by putting $dv=0$ in (32), dividing by dt and transposing, which gives the required relation in the form (30) if we observe that the isothermal elasticity $(dp/dv)_t$ is the reciprocal of the isothermal compressibility $(dv/dp)_t$.

Second Relation—From the first thermodynamical relation, as given in equation (29), Clapeyron deduced his second relation, for the heat evolved in isothermal compression, by substituting for $(dp/dt)_v$ the expression given in (30), which leads immediately to the corresponding expression for $(dQ/dp)_t$,

$$T(dv/dt)_p = -J(dQ/dp)_t \quad (33)$$

in terms of the coefficient of expansion at constant pressure. The negative sign in this relation indicates that heat is *evolved* by an increase of pressure, whereas heat is absorbed when the volume increases. There are several other thermodynamical relations, which are in effect equivalent to Carnot's equation (24), but the two originally given by Clapeyron are the most useful, and suffice for the majority of practical requirements. It will be observed that they are not independent relations, since one can be deduced from the other by a purely mathematical transformation, but either may be employed as required with the certainty of obtaining results consistent with the laws of thermodynamics

Specific Heats.—The specific heats are among the most familiar and useful coefficients in practice since they are commonly required for calculating quantities of heat. They are usually measured by observing the quantity of heat given up by a body in cooling through a large range of temperature, and are often treated as constants But in addition to the variation with temperature, as illustrated in the articles HEAT and CALORIMETRY, the results found may depend to a great extent on other conditions, such as pressure, in a manner subject to the laws of thermodynamics and amenable to calculation. In dealing with variable specific heats, the general expression for the specific heat of any substance at a temperature T is the ratio dQ/dT of the small quantity of heat dQ supplied per unit mass to the corresponding rise of temperature dT produced; but it is also necessary to specify the conditions under which the measurement is made, as these may affect the result. The two simplest cases are those in which the specific heat is measured, (a) at constant pressure, (b) at constant volume, though the latter condition can seldom be realised satisfactorily in the case of a solid or liquid For this reason it is useful to have a relation giving the specific heat at constant volume in terms of that at constant pressure. The required relation may be obtained most directly by the aid of Clapeyron's relation (33) in the following manner, which also gives incidentally the expression for any other variety of specific heat.

Difference of Specific Heats.—To find a general expression for the specific heat dQ/dT under any condition, write down the general expression for dQ in terms of dt and dp, exactly as for v in (32), by simply replacing the letter v in (32) by the letter Q, and divide each term in the expression by dt, thus we obtain,

$$dQ/dt = (dQ/dt)_p + (dQ/dp)_t dp/dt. \quad (34)$$

The first term on the right, namely $(dQ/dt)_p$, representing the heat absorbed per unit mass per degree rise of temperature at constant pressure, is obviously the specific heat as ordinarily measured at constant pressure, which may be denoted by S_p. The next coefficient, $(dQ/dp)_t$, represents the heat evolved per unit mass per unit increase of p in isothermal compression The value of this is given by Clapeyron's second relation (33) in terms of the coefficient $(dv/dt)_p$ Since the specific heat is usually required in thermal units, it is best to retain the reduction factor $1/J$, explicitly in equations expressed in thermal units, in which it is usually represented by the single letter a for convenience in writing or printing. The last factor dp/dt must be taken to correspond with the condition under which the specific heat dQ/dt is desired. Thus if we require the specific heat at constant volume $(dQ/dt)_v$, or S_v, we must also append the suffix v to dp/dt implying that it must be taken at constant volume Making these substitutions in (34) we obtain the required expression for S_v,

$$S_v = (dQ/dt)_v = S_p - aT(dv/dt)_p(dp/dt)_v \quad (35)$$

Saturation Specific Heat—As a further illustration of the same method, if we require the specific heat S_s of a wet vapour maintained in the state of saturation, implied by the suffix s, we have merely to replace the suffix v in (35) by the suffix s, thus,

$$S_s = (dQ/dt)_s = S_p - aT(dv/dt)_p(dp/dt)_s \quad (36)$$

in which $(dp/dt)_s$ represents the rate of increase of saturation pressure p with temperature, which is usually much larger than $(dp/dt)_v$ for the *dry* vapour. For this reason S_s is often negative, whereas S_v though smaller than S_p, is always positive. Thus, in the case of wet steam at 100° C, $S_s = -1\ 04$

By means of these and similar relations the variation of any specific heat can be calculated if one specific heat, such as S_p or S_v is known by experiment at the required temperature. In some cases these variations may be considerable, especially near the critical point of any substance In general, if the path on the indicator diagram along which the specific heat is to be measured approaches the isothermal, the specific heat will become very large. If the path coincides with the isothermal, the specific heat becomes infinite, because there is finite absorption of heat while $dt=0$ When the path on the diagram is a little steeper than the isothermal the specific heat becomes *negative*, changing from positive to negative infinity in crossing the line. For any path between the isothermal and the adiabatic the specific heat is negative, falling to zero when the path coincides with the adiabatic ($dQ=0$), and changing to positive again on the other side Such changes would be very troublesome to deal with in experimental work, if the thermodynamic relations did not afford a complete method of taking them into account.

Cooling Effect in Adiabatic Expansion.—The efficiency of any heat engine depends primarily on the range of temperature through which the working fluid can be cooled while converting its heat energy into work done in adiabatic expansion. It is important for this reason to be able to observe and calculate the cooling effect, which is most conveniently defined as the ratio of the drop of temperature dt to the drop of pressure dp under the condition that no heat is supplied to the working fluid, and that the expansion is frictionless and reversible The heating effect in compression is the same coefficient with the signs of both dp and dt reversed, so that its value is the same as that of the cooling effect in expansion. To find a thermodynamic expression for the cooling effect under the condition $dQ=0$, we may put $dQ/dt=0$ in the general expression (34) for the specific heat; in which case we must also take dp/dt in (34) under the same condition at constant Q, *i.e*, we must write $(dp/dt)_q$, which is the reciprocal of the required cooling effect $(dt/dp)_q$. Substituting as before from Clapeyron's relation (33), we obtain immediately,

$$S_p(dt/dp)_q = +aT(dv/dt)_p \quad (37)$$

which gives a general expression for the cooling effect, in terms of the specific heat and the coefficient of expansion, both at constant pressure, and comparatively easy to determine by experiment.

Thus if the specific heat of a *liquid* and its coefficient of expansion are known, as is the case for most liquids, it is easy to calculate the heating effect of a sudden compression. The effect is zero for water at its point of maximum density, but increases rapidly with the coefficient of expansion, since S is nearly constant.

In the case of a *gas or vapour*, which approximates to the equation $aPV=RT$ at low pressures, since (dV/dt) approaches the limit R/aP, the expression for the cooling effect becomes RT/SP, corresponding to the adiabatic equation in the form (10), with $S/R=n+1$. This shows that, if a vapour, like steam, obeys an adiabatic equation of this type with n constant, the limiting value S_0 of its specific heat at zero pressure must be constant, *i.e.*, independent of the temperature. Conversely in the case of a gas, such as hydrogen, which follows the law $aPV=RT$ very accurately, there will be no variation of S with pressure, but any variation of S with temperature requires a corresponding variation in the index $n+1$, and in the cooling effect, which is equal to $T/(n+1)P$ In such a case, it is often much easier to measure the cooling effect directly with a thermometer of a well adapted type, than it is to measure the specific heat itself at high or low temperatures. The variation of the specific heat with temperature may then be deduced from observations of the cooling effect. This method was applied by Makower (*Phil. Mag*, Feb. 1903) to verify the constancy of S in the case of steam by observing the cooling effect in a jacketed vessel, at 110° C By allowing the steam to expand suddenly from a pressure of 81 cm to atmospheric and observing the corresponding drop of temperature, he found a value of the index $\gamma=1\ 304$, agreeing closely with that deduced from the engine experiments at much higher temperatures and pressures, as previously described Brinkworth (*Proc Roy Soc*, 1925) employed a similar method for verifying the variation of the specific heat of hydrogen at low temperatures It will readily be understood that it is most important in all such cases to have an exact thermodynamical relation such as (37) between the coefficients to be measured Otherwise the interpretation of the results is apt to be uncertain Thus it is usually possible to allow for the small variations of dv/dt in reducing the results, and similarly for the variations of S with pressure.

The Joule-Thomson Cooling-effect.—This is the most important coefficient of its type, and is most easily measured in steady flow It was first measured by Joule and Thomson (1852), and was defined by them as the ratio of the drop of temperature to the drop of pressure in a pure throttling process, in which the kinetic energy generated by the pressure-drop is completely reconverted into heat without any external heat-loss Under these conditions, as explained previously, the value of H is the same after passing the throttle as in the initial state, except that in any actual experiment at high temperatures it is necessary to make a small correction for heat-loss Since H remains constant in a pure throttling process, the cooling-effect in throttling may be defined as the ratio of dT to dP at constant H and may be denoted by $(dT/dP)_H$ provided that we are dealing with small changes of temperature. In the example previously cited we were concerned only with the fact that the value of H at the high initial pressure and temperature must be the same as that observed at atmospheric pressure after throttling when corrected for heat-loss. The drop of temperature amounted to upwards of 300° C, but the cooling effect represented by the ratio, 300·3°/3789 lb, or 0·07925° per lb, does not enter explicitly into the calculation, though it might be described as the *mean* cooling effect over the given range. To find the limiting value of the cooling-effect *at* a particular temperature and pressure, it is of course necessary to make measurements over much smaller ranges of temperature.

Variation of H with P.—The cooling-effect C at constant H as thus defined, is the ration of the two partial differential coefficients of H with respect to P and T, thus,

$$C=(dT/dP)_H=-(dH/dP)_T/(dH/dT)_P \tag{38}$$

This does not involve thermodynamics, but is merely a special case of the formal relation (30), as is easily verified by writing H in place of V in (30). Putting S for $(dH/dT)_P$ the specific heat at constant pressure, we have the useful relation $(dH/dP)_T=-SC$, giving the variation of H with P at constant T in terms of the specific heat S and the cooling effect C, which are the most easily measured of all coefficients. Another expression for the same coefficient may be obtained by applying the two laws of thermodynamics. From the first law in the form $dH=dQ+aVdP$, as given in (5), dividing by dP at constant T, we find,

$$(dH/dP) = (dQ/dP)_T+aV=-aT(dV/dT)_P+aV \tag{39}$$

in which the second law is involved in the substitution for (dQ/dP) from Clapeyron's second thermodynamical relation (33).

Joule-Thomson Equation.—The utility of relation (39) lies in the fact that it supplies the necessary and sufficient condition which must be satisfied by any expressions selected to represent H and V (the two most important thermodynamical properties of any substance) in order to render such expressions consistent with the laws of thermodynamics. Joule and Thomson made use of (39) in the form

$$SC=aT^2(d(V/T)/dT)_p \tag{40}$$

in order to deduce an expression for V consistent with their observations on the cooling-effect. Their experiments showed that C was approximately independent of the pressure, but varied as $1/T^2$ with temperature for air and CO_2 over the range 0° to 100° C. Integrating (40) at constant P, with S constant, and $C=K/T^2$, they obtained the solution:

$$-SK/3T^3=aV/T-R/P \tag{41}$$

in which the constant of integration R/P was determined by the condition that the equation must approximate to the form $aPV=RT$ when T is very large. The small term $SK/3T^3$, which may be written $SC/3T$, represents the deviations of the actual gas, air or CO_2, from the ideal state, in terms of the observed values of S and C for the gas employed. Thus equation (41) makes it possible to deduce the absolute temperature T from the observed temperature by air thermometer as defined in terms of P and V, but the process of reduction (for which *see* the article THERMOMETRY), is far from being as simple as it might appear to be at first sight. Moreover the original Joule-Thomson equation as given in (41), though it showed that the deviations of air from the ideal state must be very small, was somewhat unsatisfactory in other respects. It failed to explain the heating-effect observed in the case of hydrogen, and made no allowance for the known variation of specific heat in the case of CO_2. These difficulties may be avoided in practice by reversing the procedure Assume a convenient type of equation for V, differentiate to find the expression for SC as in (39), and determine the constants by comparison with experimental results for S and C

Modified Equation—A suitable equation of a type similar to (41), is the following,

$$V-b=RT/aP-c, \text{ where } c=c_1(T/T)^n \tag{42}$$

The small constant b, called the covolume, may be regarded as representing the limiting volume of the molecules at high temperatures and pressures. The small correction term c, called the coaggregation volume, represents the defect from the ideal volume caused by coaggregation or pairing of molecules. This is assumed to vary inversely as the nth power of T, and c_1 is the value of c at any convenient temperature T such as 0_0 C On this assumption c is a function of the temperature only, and $dc/dt=-nc/T$ Differentiating equation (42) in order to find SC as given by (39) or (40), we obtain,

$$SC=aT(dV/dT)_P-aV=a(n+1)c-ab \tag{43}$$

from which the values of the constants c, n, and b, may be deduced, when the values of S and C are known by observations taken over a sufficient range. It is easy in this way to take account of any variations of S with temperature or pressure. The slope of the isothermals on the Amagat diagram, in which PV is plotted against P, is represented by $d(PV)/dP=-c+b$, and is *positive* in the case of hydrogen (for which PV increases with P) because b is so much larger than c at ordinary temperatures. For the same reason the cooling effect C is *negative*, as found by Joule and Thomson, who observed a *rise* of temperature with *drop* of pressure in throttling. This result is explained by (42), if b exceeds $(n+1)c$, as is actually the case with hydrogen.

Expression for the Total Heat H.—The same equation (42) may be employed as a simple illustration of the general method of deducing consistent expressions for the total heat and the entropy of a substance when an equation for V in terms of P and T has

been obtained by the above method. To find an expression for H we start with the general formula for dH in terms of S and C, thus,

$$dH = SdT - SCdP. \qquad (44)$$

Since the value of H depends only on the state, we may perform the integration along any convenient path, starting from any convenient zero The simplest method is to integrate the first term from 0 to T at zero pressure, since the value of S at zero pressure, denoted by S_0, is a function of the temperature only. We may denote this integral by S_mT where S_m is the mean value of S_0 from 0 to T. We then have to add the integral of the second term at constant T from $P=0$ to P. In the present case, since SC is a function of T only, as given by (43), the integral of $SCdP$ is simply SCP. Adding the two terms, we obtain the general expression for H at T and P,

$$H - B = S_mT - SCP \qquad (45)$$

in which the constant of integration B is determined by reference to any known value of H at some definite point, such as 100° C and atmospheric pressure In the case of steam, S_m may be taken as constant and equal to S_0.

Variation of the Specific Heat S with Pressure.—According to (45) the specific heat S at constant pressure will be a function of both temperature and pressure The required expression for S is easily obtained by differentiating (45) at constant pressure, thus,

$$S = (dH/dT)_p = S_0 + an(n+1)cP/T. \qquad (46)$$

This shows that, with an equation of the type (41) or (42), S cannot be constant, as assumed by Joule and Thomson in the integration of (40), and invalidates their method of deducing (41), but the same objection does not apply to the reverse procedure employed in deducing (42). The variation of S with pressure at constant temperature for any equation of this type can also be obtained from the consideration that H is a definite function of P and T depending only on the state, so that if we differentiate S as found in (46) with regard to P at constant T, we must obtain identically the same result, namely $d^2H/dPdT$, as by differentiating $(dH/dP)_T$ (or $-SC$) with regard to T at constant P. Using the general expression for SC given in (39), we obtain,

$$(dS/dP)_T = -(dSC/dT)_P = -aT(d^2V/dT^2)_P \qquad (47)$$

which shows that S cannot be independent of the pressure, if SC is a function of the temperature. From another point of view (47) represents the condition that dH as given in (44) should be the exact differential of a definite function of P and T, as must be the case if H is a property of the substance depending only on the state as defined by P and T. On the other hand if we apply the same condition to the general expression for dQ, namely,

$$dQ = SdT - aT(dV/dT)_P dP \qquad (48)$$

we observe that (47) cannot be satisfied in the case of dQ consistently with the second law of thermodynamics, because the heat added in any transformation is not simply a property of the substance depending on the initial and final states, but depends essentially on the process by which the transformation is effected In other words, dQ is not the exact differential of any function of P and T, and cannot be integrated without knowing the relation between P and T defining the process But if the path is given, Q can always be found from (48). Thus if the path on the indicator diagram is a straight line defined by $dP = kdT$, $dQ/dT = S - akT(dV/dT)_P$, and the required value of Q can be found for any substance for which the specific heat and the coefficient of expansion are known. The heat required for any transformation is often required in practice, and may always be obtained in this way, if the path is given.

Expression for the Entropy Φ.—If a small quantity of heat dQ per unit mass is supplied to any substance at a temperature T, the corresponding increase of entropy $d\Phi$ is dQ/T. Thus we obtain immediately from (48),

$$d\Phi = dQ/T = (S/T)dT - a(dV/dT)_P dP. \qquad (49)$$

If we apply the mathematical test for an exact differential, as in (47), we find,

$$(d[S/T]/dP)_T = (1/T)(dS/dP)_T = -a(d^2V/dT^2)_P \qquad (50)$$

which, it will be observed, is precisely the same as that found for dH. We conclude that Φ like H may be regarded as a property of the substance depending only on the state, and capable of tabulation in terms of P and T.

Since Φ itself cannot be measured in practice in any convenient manner, it is usually deduced for any substance from the expression found by experiment for H Since $dQ = dH - aVdP$, by (5), taking dH from (44), we obtain,

$$d\Phi = dQ/T = (S/T)dT - (SC/T + aV/T)dP \qquad (51)$$

which is seen to be identical with (49) if we substitute for SC from (39). This may be integrated, as in the case of H, from 0 to T at zero pressure, with $S = S_0$, and from 0 to P at constant T. Taking as an example the simple equation (42) for V, with SC from (43), we find the expression,

$$\begin{aligned}\Phi - A &= \int(S_0/T)dT - \int(R/P + anc/T)dP \\ &= S_0 \ln T - R\ln P - ancP/T \qquad (\ln = \text{rat. log}) \qquad (52)\end{aligned}$$

in which A is the constant of integration determined in the usual manner.

Use of the Entropy—It should be observed that the entropy is not an independent property of the substance, since it can be deduced from H and V, but it is most useful in practice for defining the process of frictionless adiabatic expansion, and for deducing the maximum work obtainable from a quantity of heat supplied to the working substance under specified conditions. As a simple example we may take the case of the steam-turbine. Any part of the heat received (e g , in the superheater) at the constant initial pressure P' is represented in virtue of relation (3) by the increase DH of the total heat of the steam over the range considered Let $D\Phi$ represent the increase of entropy taken from the tables over the same range of temperature In the ideal cycle after adiabatic expansion the corresponding part of the heat rejected at the constant temperature T'' of the condenser will be $T''D\Phi$. The difference $DH - T''D\Phi$ represents the work obtainable from this part DH of the heat supplied, and the ideal efficiency is given by $1 - T''D\Phi/DH$. Thus it becomes possible to estimate the thermal efficiencies of different stages of the heating system, as depending on the temperature T' of heat reception by the working fluid.

The equivalent of the work theoretically obtainable in any part of an ideal cycle included between two adiabatics may also be found by subtracting the heat-drop along the lower adiabatic from that along the higher adiabatic This gives the same result as subtracting the heat rejected from the heat received, but saves trouble in calculation if tables of adiabatic heat-drop are available.

If the "mean effective temperature" T_m of heat reception DH at constant pressure P is defined as being equal to $DH/D\Phi$, the expression for the ideal efficiency of the cycle between the two adiabatics differing in entropy by $D\Phi$ reduces to the form $1 - T''/T_m$, the same as that of a Carnot cycle in which all the heat is received at one temperature T_m. As G M Clarke has pointed out, the mean effective temperature thus defined affords a convenient method of expression for the ideal efficiency of any cycle as compared with the Carnot cycle. But it does not supersede the use of the entropy, which is required in order to be able to calculate T_m.

Efficiency of Expansion in a Turbine—The foregoing method of finding the efficiency of *an ideal cycle*, or part of a cycle, between two adiabatics, depends on assuming that the useful work done is equal to the excess of the heat received over that rejected by the working fluid, and is restricted to the case in which no losses are incurred in expansion, and all the heat is rejected at one temperature T'', as in the condenser of a steam-engine or turbine. The method gives the fraction of the heat received in any part of *the heating system* which could be converted into work by a *perfect* engine under the conditions imposed. On the other hand, in analysing the performance of an actual engine or turbine, it is necessary to take account of losses incurred *in the engine* during the expansion, and to compare the actual performance with that obtainable in adiabatic expansion under ideal conditions over the same range. The general principle of the method by which this may be accomplished in the case of a

turbine is as follows:

The Case of Dry Steam.—As explained previously, and implied by equation (12), the drop of H in expansion through a turbine, when corrected for the minor losses Q and K, is the equivalent of the useful work done by the steam. So long as the steam is *dry*, the value of H at any point of the expansion can be determined by observing the pressure and temperature, and the actual drop of H, denoted by DH, between any two points can be deduced. The work theoretically obtainable in frictionless expansion can also be found from the adiabatic equation as shown in (17). The ratio of the actual heat-drop DH, as corrected, to the adiabatic heat-drop for the same drop of pressure, gives the efficiency of any stage or section of the turbine. This simple method fails when the steam is *wet*, as usually happens towards the end of the expansion, because there is no satisfactory means of measuring the degree of wetness under these conditions at low pressures. But if the initial value Φ of the entropy is known, the adiabatic heat drop can still be found from the final temperature T'', with the aid of the tables giving H_s'' and Φ_s'' for *dry saturated* steam, since for *wet* steam in the state H'', Φ'', at any temperature T'' we have the simple relation,

$$H_s''-H''=T''(\Phi_s''-\Phi''). \quad (53)$$

Heat-Drop for Wet Steam—Putting $\Phi''=\Phi'$ in (53) the final H'' for wet steam at T'', in adiabatic expansion, is obtained in terms of the tabulated values H_s and Φ_s. Thus we obtain for the adiabatic heat-drop from the initial state H', Φ'.

$$H'-H''=H'-H_s''+T''(\Phi_s''-\Phi') \quad (54)$$

Equation (54) is also the appropriate equation to employ for finding the adiabatic heat-drop over the whole range of expansion in the turbine, from admission to exhaust, when the final state of the steam is wet, as is usually the case with a condensing engine. It is equally applicable to the case of a reciprocating engine, since the discontinuities involved in the operation of this type of engine are supposed to be absent from the ideal cycle. The heat-drop thus found may be compared with the work actually done per lb. of steam, as deduced from measurements of the feed and the power, for which *see* STEAM-ENGINE

Equation (53), with Φ'' constant and equal to Φ' may be regarded as the simplest and most useful form of the adiabatic giving the final value H″ of the total heat for a wet vapour, when tables of Φ and H are available It may be expressed if desired in terms of H and T only, but cannot be put in the usual form (9) or (10) (as is often attempted), because the value of the index γ varies so much with temperature and wetness as to make the equation difficult to use and less accurate in practice than measurements on a diagram

Types of Characteristic Equation.—The general relation between P, V, and T, which exists for any substance in various states is commonly called the characteristic equation, or equation of state, of the substance. It has often been thought possible to include both liquid and vapour states in a single equation, such as that of van der Waals, since the properties of the two states approximate to each other in the critical region, and show a continuous transition above the critical pressure This will be further discussed in the article VAPORIZATION dealing with the relations between the two states. For the present purpose we may confine our attention to a few simple types of equation for the gas or vapour state, which is of primary importance in practice in relation to heat engines. It appears that all simple substances with stable molecules tend to approximate in the vapour state at low pressures to the ideal gas equation $PV=RT$, in which the value of the constant R varies inversely as the molecular weight (if V is the volume of unit mass) and is equal to the difference of the specific heats in work units. An equation of this type receives a satisfactory physical explanation on the kinetic theory of gases, but it is the province of thermodynamics to indicate how the simple gas equation must be modified to take account of deviations from the ideal state, and to interpret the results of various experimental methods as applied to the problem.

One of the commonest methods of measuring these deviations is to observe the variation of the volume with pressure at constant temperature. The values of the product PV should then be constant if Boyle's law is obeyed, and should give a horizontal line on the $PV-P$ diagram. As a rule the isothermal lines thus plotted from observations at various constant temperatures, are nearly straight for a moderate range of pressure at each temperature, but have a downward slope, represented by $d(PV)/dP=-c$, where c diminishes with rise of temperature as the vapour approximates more closely to the ideal state. Observations of this kind could be represented by an equation of the type (42) by assuming PV to be proportional to T at low pressures, and choosing c, or $c-b$, to be a suitable function of the temperature But even if all the isothermals were found to be horizontal, this method by itself would not prove that PV was proportional to the absolute temperature, as in $PV=RT$, since Boyle's law would be perfectly satisfied by an equation of the type, $PV=F(T)$, with $F(T)$ any arbitrary function of the temperature

Fortunately the Joule-Thomson method, as described on page 98, affords an independent means of verifying the form of the characteristic equation. It has the additional advantages of being easy to apply and of measuring the small deviation itself, without requiring any absolute measurements of volume, which are essential to the Boyle's law method, and very exacting. As shown by the thermodynamic expression (40) for the cooling effect, any substance for which $C=0$ must have a characteristic equation of the general type $V/T=F(P)$, in which $F(P)$ represents any arbitrary function of the pressure. The ideal gas, $PV=RT$ is a special case for which $F(P)=R/P$. The condition $C=0$ by itself leaves the form of $F(P)$ indeterminate. But when the same gas also satisfies Boyle's law, which requires a characteristic equation of the form $PV=F(T)$, the two conditions can be simultaneously satisfied only by the ideal gas equation $PV=RT$. Joule and Thomson were therefore justified in their choice of the constant of integration R/P in equation (41), since the gases they employed also satisfied Boyle's law at low pressures

Type of Equation Required by Condition (6)—Another case of practical interest is to find the general form of characteristic equation compatible with condition (6), and with the simple form of adiabatic equation (9), which follows by the first law of thermodynamics from the assumption that the change of intrinsic energy is proportional to that of aPV as expressed in (6) Equations (6) and (9) make no mention of temperature, and it is obvious that the deduction of the relation between PV and T must essentially involve an appeal to the second law with its implicit definition of T. The most direct way of doing this is to find the two specific heats, S_p and S_v, from H and E as given by (6), and to equate the difference, S_p-S_v, thus found to the expression (35) for the difference of the specific heats as given by the second law Thus by differentiating (6) at constant volume we obtain for the specific heat S_v,

$$S_v=(dE/dT)_v=an(V-b)(dP/dT)_v \quad (55)$$

Similarly by adding aPV to (6) to give $H-B$ instead of $E-B$, and differentiating H at constant pressure, we obtain for the specific heat S_p,

$$S_p=(dH/T)_p=a(n+1)P(dV/dT)_p. \quad (56)$$

Substituting the difference of these two expressions for S_p-S_v in (35), and dividing by $a(dP/dT)_v(dV/dT)_p$, we obtain the required expression for T in terms of P and V in the form of a differential equation, namely,

$$T=(n+1)P(dT/dP)_v-n(V-b)(dT/dV)_p \quad (57)$$

which is a special case of Lagrange's linear equation, and is easily solved as follows.

(a) Write down the corresponding subsidiary equations of Lagrange, namely,

$$dT/T=dP/(n+1)P=-dV/n(V-b) \quad (58)$$

(b) Find any two independent solutions of these equations. The two simplest and most obvious solutions of (58) are those given in (10) above, which are alternative forms of the adiabatic equation, and are also solutions of (57). (c) To find the most general solution, including all other possible solutions, make one of these ex-

pressions an arbitrary function of the other. This will be the most general form of characteristic equation consistent with (6) and (9). The most convenient form for most practical purposes, giving V explicitly as a function of P and T, is as follows,

$$P(V-b)/T=F(P/T^{n+1}) \tag{59}$$

which is expressed in words by stating that $P(V-b)/T$ must be constant along any adiabatic represented by $P/T^{n+1}=$ constant Thus (59) includes all possible forms of characteristic equation consistent with the adiabatic found experimentally for steam, and with the expression (6) for the intrinsic energy, which was assumed as the basis of the equations first proposed for steam by the writer (*Proc. R S* 1900, p. 269) At that time none of the experimental evidence available, except that for the adiabatic, extended much beyond 200 lb pressure and 200° C, and the state of knowledge did not justify going further than the first approximation represented by equation (42), in which the arbitrary function F was assumed to be of the simple form $R/a-cP/T$ This proved to be a very good approximation and amply sufficient at moderate pressures or high superheats, but it appeared that higher powers of cP/T would be required at higher pressures, and that no equation of this type could represent the accepted theory of the critical state, as represented by the van der Waals equation

While retaining the fundamental assumption (6) it would evidently be possible to construct an equation of the van der Waals type, giving P as a cubic function of $1/(V-b)$, by replacing P/T^{n+1} in (59) by $1/(V-b)T^n$, as follows,

$$aP(V-b)/RT=1-c/(V-b)+c^2/3(V-b)^2 \tag{60}$$

which would give a critical point of the usual type defined by the conditions,

$$V-b=c=RT/3aP, \tag{61}$$

but in the absence of accurate experimental data it was impossible to predict that this would be more satisfactory than (59) in terms of P, whereas it would certainly be much less convenient for practical calculations

It has recently been found possible (*Proc. R S* Sept 1928), to extend the experimental range for water and steam to 400° C and 4,000 lb pressure, including the whole of the critical region Results obtained for water, by the steady flow method described in the article CALORIMETRY, verify the thermodynamic equation there given for the total heat with extreme accuracy up to the critical point Those for steam disagree materially on several fundamental points with the accepted theory of the critical state, and appear to show that an equation of the type (59) is capable of representing the critical phenomena with much greater accuracy than any equation of the van der Waals type Since the points in question are of primary importance with respect to the relations between the liquid and vapour states, they are further discussed in the article VAPORIZATION, though they also afford a good illustration of the application of the laws of thermodynamics to experimental research

As it would be impossible within the limits of this article to illustrate or explain adequately the applications which have been made of the principles of thermodynamics, it has been necessary to select such illustrations only as are required for reference in other articles, or could not be found elsewhere. For fuller details and explanations of the elements of the subject, the reader must refer to general treatises, such as Ewing's *Thermodynamics for Engineers* (Cambridge, 1920), Birtwistle's *The Principles of Thermodynamics* (2nd ed, Cambridge, 1927) or Preston's *Theory of Heat* (5th ed., 1928). One or two chapters on the subject are also generally included in treatises on the steam engine or other heat engines, such as those of Rankine, Ewing, or Perry. Of greater interest, especially from a historical point of view, are the original papers of Joule, Kelvin and Rankine A more elaborate treatment of the subject will be found in many foreign treatises, such as those of Clausius, Zeuner, Duhem, Bertrand, Planck and others. (H L C.)

THERMODYNAMICS AND PHYSICAL CHEMISTRY

Introductory.—The principles of thermodynamics (introduced in their modern form by Clausius in 1850) are the basis of a method of dealing with mechanical problems in which heat exchanges take place, without the necessity arising of considering the detailed mechanical structure of a system. The system may consist of an assemblage of an enormous number of molecules in agitated movement and exerting attractions and repulsions upon one another. Very little can be found out about the individual motions and positions of these particles Thermodynamics provides a means of examining certain properties of matter in bulk. The principles that are discovered form the basis of the preceding article and reference must be made to that article for their description and proof They are applied there mainly to the properties of steam and its applications to steam-engines In the present article which deals with the application to bodies in general we must be content with summarizing the fundamental facts which will be utilized

i. The intrinsic or internal energy of a body can change by the entry of heat (by conduction or radiation) and by the performance of external work, i e, $dE=dQ-dW$ provided the system remains sensibly in equilibrium (*Conservation of energy*).

ii. A body may get hotter even if no heat flows in. The energy depends on the temperature and this is increased if work is done upon the system even when dQ is zero (*Adiabatic changes*).

iii The energy, E, depends only upon the state, so that, in whatever way the system is changed, if the original state is returned to the initial value, E, is recovered

iv. The work done depends in general not only upon the initial and final states but also upon the path of transformation.

This results from the fact that three variables at least are necessary to specify the state, viz, pressure, volume and temperature, and they are connected by only one equation (the equation of state). The work done is in each case $\int pdV$. In a complete cycle the work done is equal to the area enclosed by the cycle on a p, V diagram For any given value of V, T and therefore p may have different values on the return and forward paths and the cycle encloses an area It follows that for an *isothermal* reversible cycle the pressure for any given volume is fixed and the work done must be zero for the path then returns on itself

v The energy E depends on both the temperature and the volume for internal work can be done against molecular attractions when the volume changes.

When the system is subjected to a uniform pressure the fundamental equation becomes $dH=CdT+ldv$.

We select unit mass for consideration. In this case C is the specific heat at constant volume and $l\left(=\frac{\Delta H}{\Delta v}\right)$ is the latent heat of expansion In the case of a perfect gas, for which the characteristic equation is $pv=RT$ and for which no internal attractions exist, so that the internal work is zero

$$dH=C_vdT+pdv$$

which can be put in the alternative forms (by using the characteristic equation)

$$dH=C_pdT-vdp=\frac{1}{R}(C_ppdv+C_vvdp)$$

where C_v and C_p are the specific heats at constant volume and at constant pressure.

From these for adiabatic changes ($dH=0$)

$$C_vdT+\frac{RT}{v}dv=0 \quad \text{or} \quad vT^{C_v/R}=\text{const}$$

$$C_pdT-\frac{RT}{p}dp=0 \quad \text{or} \quad \frac{T^{C_p/R}}{p}=\text{const.}$$

$$\text{and} \quad C_ppdv+C_vvdp=0 \quad \text{or} \quad pv^{C_p/C_v}=\text{const}$$

The work done is $\int pdv=-C_v\int dT=C_v(T_1-T_2)$

It is presumed that the changes are reversible throughout. A very quick change is always irreversible owing to the rushes of material that take place. The only way to bring about approximate reversibility is to keep the heat from getting in or out as well as possible by means of non-conducting boundaries.

vi. The second law of thermodynamics enables relations to be found between the several quantities (or their derived quantities). According to this law the work that can be done in a reversible Carnot cycle is the maximum possible for the two extreme temperatures concerned, and, *independently of the working substance*, the work done divided by the heat taken in at the higher temperature is equal to $(T_1 - T_2)/T_1$: where T_1 and T_2 are absolute temperatures on the perfect gas scale. This ratio is called the efficiency.

[This law is derived from the fact that heat can only flow *down* a gradient of temperature. Clausius showed that if a more efficient performance were obtainable it would be possible to make a hot body hotter while simultaneously a cold one became colder without any performance of work. This would entail that heat flowed *up* the temperature gradient.]

vii. Since the efficiency is also given by $\dfrac{W}{Q_1} = \dfrac{Q_1 - Q_2}{Q_1}$ we deduce that $\dfrac{Q_1}{T_1} = \dfrac{Q_2}{T_2}$.

Now in a Carnot cycle Q_1 and Q_2 are the only transfers of heat (each at constant temperature), if therefore we define a quantity ϕ such that $Td\phi = dQ$ this quantity ϕ undergoes zero change in any complete reversible cycle It is called the entropy of the system per unit mass.

For irreversible changes this definition is not complete In such changes there is kinetic energy of matter in bulk, and friction which is always present is continually frittering the motion down into heat If we regard the system as an assemblage of small elements rubbing against one another the heat produced flows across the boundaries of these elements. In doing so some has entered each element and produces the same changes of p, v, T and entropy as any heat entry would do. When this heat production and corresponding entropy change is summed up for the whole system we have

$$Td\phi = d(Q+q)$$

where q is the heat produced by friction inside the walls of the complete system. Since friction never produces "cold," dq is always positive and consequently for any change

$$Td\phi \geqq dQ.$$

Cases in which the equality sign holds are ideal cases only, but they are approximated to more nearly the nearer a system keeps in equilibrium states throughout.

The quantity T_1 is, as we have said, the absolute temperature according to a perfect gas scale. We could have defined it alternatively in terms of the efficiency equation and it is therefore called the *thermodynamic* temperature. It would have been necessary then to show that it is identical with the ideal gas scale.

The advantage gained by introducing the conception of entropy is that it provides us with a function of Q which depends (unlike Q itself) only upon the state of the system, provided that we measure it for reversible changes only.

viii. When any property of the state of a system (say E) is defined completely by two independent variables (say x and y) so that we can write

$$dE = adx + bdy$$

where $\quad a = \left(\dfrac{\partial E}{\partial x}\right)_y \quad$ and $\quad b = \left(\dfrac{\partial E}{\partial y}\right)_x$

the following mathematical relation must be valid, viz.:

$$\left(\frac{\partial a}{\partial y}\right)_x = \left(\frac{\partial b}{\partial x}\right)_y$$

the suffixes denoting quantities which remain constant during the partial differentiations to which they are appended

This mathematical relation can be applied in the case of reversible changes to E and ϕ which depend only on the state but it cannot be applied to Q or to W, which depend upon the path taken between the extreme states. In consequence some writers prefer not to use the expressions dQ and dW for small changes in Q and W because, for example, these may each acquire different values whether the "co-ordinates" of the system (e.g., v, T) have changed *on the whole* or not. Small changes in quantities which depend only upon the state are said to be perfect differentials.

When there are more than two independent variables we can apply the same theorem to any two of them in turn. For example, adding a third term cdz, we have the additional relations

$$\left(\frac{\partial a}{\partial z}\right)_{x,y} = \left(\frac{\partial c}{\partial x}\right)_{y,z} \quad \text{and} \quad \left(\frac{\partial b}{\partial z}\right)_{y,x} = \left(\frac{\partial c}{\partial y}\right)_{z,x}$$

where two of the independent variables are kept constant in each differentiation.

The employment of thermodynamics in the study of various systems consists very largely of the application of this important mathematical theorem. We shall apply it first to homogeneous systems in equilibrium.

Homogeneous Systems.—A homogeneous system is alike in all its parts. Its state can be defined in terms of its pressure, volume and temperature. Any one of these three may be eliminated by means of the so-called characteristic equation when it is known; so that Q, ϕ, E may be taken as functions of T and v, of T and p, or of p and v Since each portion is the same as any other we can deal with unit mass. Since equilibrium exists the temperature and pressure will be uniform throughout. No assumption will be made as to the molecular constitution of the system, nor, until applications are considered will any assumption be made as to the form of the characteristic equation.

For such a system we can write:

$$dQ = dE + pdv = C_v dT + ldv$$

also $\quad d\phi = (dQ)/T.$

so that $\quad dE = C_v dT + (l-p)dv$

and $\quad d\phi = \dfrac{C_v dT}{T} + \dfrac{l}{T}\,dv.$

It follows that (a) $\left(\dfrac{\partial C_v}{\partial v}\right)_T = \dfrac{\partial}{\partial T}(l-p)_v$

(b) $\dfrac{1}{T}\left(\dfrac{\partial C_v}{\partial v}\right)_T = \left(\dfrac{\partial}{\partial T}\,\dfrac{l}{T}\right)_v.$

The latter (b) multiplied by T gives

$$\left(\frac{\partial C_v}{\partial v}\right)_T = \frac{\partial l}{\partial T} - \frac{l}{T}$$

which, comparing with (a), gives $l = T\left(\dfrac{\partial p}{\partial T}\right)_v$

and $\quad \left(\dfrac{\partial C_v}{\partial v}\right)_T = T\left(\dfrac{\partial^2 p}{\partial T^2}\right)_v.$

For a perfect gas $pv = RT$, whence $T\left(\dfrac{\partial p}{\partial T}\right)_v = p$ and $\left(\dfrac{\partial C_v}{\partial v}\right)_T = 0.$

For a van der Waals gas $\left(p + \dfrac{a}{v^2}\right)(v-b) = RT$, so that

$$T\left(\frac{\partial p}{\partial T}\right)_v = p + \frac{a}{v^2} \quad \text{and} \quad \left(\frac{\partial C_v}{\partial v}\right)_T = 0;$$

whence $dQ = C_v dT + \dfrac{adv}{v^2} + pdv$; the term $\dfrac{a}{v^2}dv$ shows how the energy depends upon the volume.

It will be noticed that these are all cross-relations between different terms. There is no thermodynamical relation giving $\dfrac{\partial C_v}{\partial T}$ because C_v and T both refer to the same term. We know nothing about C_v as a function of T except from experiment and from tentative mechanical theory.

In a similar way if $dQ = C_p dT + l'dp$ (T and p being taken as independent variables) we have

(a) $\quad dE = C_p dT + l'dp - pdv$

and (b) $\quad d\phi = \dfrac{C_p dT}{T} + \dfrac{l'dp}{T}.$

Now $d(pv) = pdv + vdp$; and if this be added to both sides of (a) we have $d(E+pv) = C_p dT + (l'+v)dp$. Since, the product pv

returns to a fixed value whenever p and v do therefore $E+pv$ also depends on the state alone and its change is defined here in terms of dT and dp. Hence

$$\left(\frac{\partial C_p}{\partial p}\right)_T = \left[\frac{\partial}{\partial T}(l'+v)\right]_p$$

and

$$\left[\frac{\partial}{\partial p}\left(\frac{C_p}{T}\right)\right]_T = \left[\frac{\partial}{\partial T}\left(\frac{l'}{T}\right)\right]_p$$

which yield finally $l' = -T\left(\frac{\partial v}{\partial T}\right)_p$ and $\left(\frac{\partial C_p}{\partial p}\right)_T = -T\left(\frac{\partial^2 v}{\partial T^2}\right)_p$

It is to be noted that these equations in reality express the connections that must exist between the properties of a substance in order to bring about the universality of the value of the efficiency if the substances were employed as the working substances in reversible engines working between two given temperatures. A high vapour pressure or a low boiling point does not lead to higher efficiency, the variables being so interconnected that this is impossible.

The above equations hold for any homogeneous systems. The equation

$$dQ = C_v dT + T\left(\frac{\partial p}{\partial T}\right)_v dv$$

is exceedingly important, embodying all that can be learned from the two thermodynamical principles, and serving as a secondary starting point from which other relations may be obtained without further reference to the two principles. For example if x is any other variable we can write

$$\left(\frac{dQ}{dT}\right)_x = C_v + T\left(\frac{\partial p}{\partial T}\right)_v \left(\frac{dv}{dT}\right)_x$$

the suffix x indicating that x is to be kept constant during the differentiation For example, if $x=p$ (the pressure), $\left(\frac{dQ}{dT}\right)_x = C_p$ (the specific heat at constant pressure) and we have

$$C_p = C_v + T\left(\frac{\partial p}{\partial T}\right)_v \left(\frac{\partial v}{\partial T}\right)_p$$

which is an expression for the difference between the two principal specific heats For a perfect gas the right hand side equals R, the gas constant. For a van der Waals fluid it equals

$$R \Big/ \left(1 - \frac{2a}{v^3}\cdot\frac{(v-b)^2}{RT}\right).$$

Berthelot's equation of state is very widely used in calculating the difference of the specific heats. The equation is

$$\left(\alpha + \frac{16}{3\gamma\beta^2}\right)\left(\beta - \frac{1}{4}\right) = \frac{32}{9}\gamma.$$

It is given here in its "reduced" form; *i.e.*, the actual pressures, volumes and temperatures are given as the fractions α, β, γ of their respective critical values Calculating in the same way, this equation leads to

$$C_p - C_v = \frac{32}{9}\frac{p_c v_c}{T_c}\left(1 + \frac{6}{\gamma^2\beta}\right) \text{ approximately}$$

when β is large compared with unity. This can be written

$$C_p - C_v = R\left(1 + \frac{6}{\gamma^2\beta}\right) \doteq R\left(1 + \frac{27}{16}\frac{\alpha}{\gamma^3}\right)$$

where R is the characteristic constant of the gas.

Callendar's simplified equation, $v-b=RT/p-c/T^n$ leads to

$$C_p - C_v = R\left(1 + \frac{ncp}{RT^{n+1}}\right)^2.$$

The last two equations are only applicable when the density is moderate.

Saturation Values.—As a second application, let x denote a change along the line of saturated vapour; then $\left(\frac{dQ}{dT}\right)_x$ becomes σ, the specific heat of saturated vapour, and

$$\sigma = C_v + T\left(\frac{\partial p}{\partial T}\right)_v \left(\frac{\partial v}{\partial T}\right)_{\text{sat.}}$$

Now $\left(\frac{\partial p}{\partial T}\right)_v$ is always positive and $\left(\frac{\partial v}{\partial T}\right)_{\text{sat}}$ is always negative so that σ is always less than C_v and it may even be negative This latter is the case for steam at all temperatures The values for sulphur dioxide have also been studied in detail experimentally by Mathias (*Comptes Rendus*, t cxix. p 849) The importance of this substance in mechanical refrigeration warrants quoting the values in some detail·

t° C	0	20	40	60	80	100	110
σ	−0 410	−0·357	−0 300	−0·235	−0·165	+0 027	+0·062
t° C	120	125	130	140	150	155	
σ	−0·078	−0·176	−0·306	−0 620	−1 253	−3·850	

It appears that for this substance σ is negative except between the temperatures 97·5° C and 114° C. When plotted against temperature the curve is an inverted unsymmetrical U. This is so for all substances but in many cases it lies wholly in the negative region. The value of σ for the liquid along the saturation line has also been studied by Mathias It is positive (because for the liquid $\left(\frac{\partial v}{\partial T}\right)_{\text{sat}}$ is positive) and changes from 0·315 at −20° C to 1·800 at 155° C

We can start equally well from the equation

$$dQ = C_p dT - T\left(\frac{\partial v}{\partial T}\right)_p dp$$

and find

$$\sigma = C_p - T\left(\frac{\partial v}{\partial T}\right)_p \left(\frac{dp}{dT}\right)_{\text{sat}}.$$

The thermodynamic equations employed above are exact. It should be noted, however, that the characteristic equations are only approximate at best. The underlying assumption that is made in deriving them is that the system consists of molecules alike in all respects. Even in such a case it is not to be expected that the p, v, T, equation should be of a simple form. It is much simplified by the fact that we are only concerned with average values No instrument is capable of measuring either the pressure or temperature at a single point and a single moment of time. Each quantity measured is an average value over such a volume or area or time as to maintain a constant value in the equilibrium state. For real fluids molecules may be of different kinds and may be associated with one another in different ways which change with the volume and temperature. In such cases the connection between p, v and T is bound to be of a more elaborate character The only assumption that has been made is that for a definite p, v, T, the constitution is the same whenever these return, after changes, to their original values

Entropy.—Since $dQ=C_v dT+pdv$ for a perfect gas the entropy change is

$$d\phi = \frac{dQ}{T} = C_v\frac{dT}{T} + \frac{R}{v}dv;$$

whence

$$\phi_2 - \phi_1 = C_v \log_e\frac{T_2}{T_1} + R\log_e\frac{v_2}{v_1}$$
$$= C_p \log_e\frac{T_2}{T_1} - R\log_e\frac{p_2}{p_1}.$$

For a van der Waals fluid

$$dQ = C_v dT + T\left(\frac{\partial p}{\partial T}\right)_v dv$$
$$= C_v dT + \frac{RT}{v-b}dv$$

and

$$\frac{dQ}{T} = C_v\frac{dT}{T} + \frac{R}{v-b}dv.$$

Now C_v for such a fluid may be a function of T but not of v, and

experiment shows that, for many gases, it is very nearly a linear function of T through a range of seven or eight hundred degrees centigrade If we write $C_v = c + gT$

$$\phi_2 - \phi_1 = c \log\frac{T_2}{T_1} + g(T_2 - T_1) + R\log\frac{v_2 - b}{v_1 - b}.$$

Thermodynamic Potentials.—It has been explained that, when the possibility of irreversible changes is taken into account the increase in entropy is always greater than that calculated from the heat entry from outside the system, *i.e.*, we may write

$$Td\phi = dQ + Pos$$

where *Pos* is a positive quantity In the ideal case of a reversible change this positive quantity becomes zero. For any change therefore

$$\begin{aligned} dE &= dQ - pdV \\ &= Td\phi - pdv - Pos. \end{aligned}$$

If we subtract $d(T\phi)$ from both sides

$$d(E - T\phi) = -\phi dT - pdv - Pos.$$

If the change is at constant temperature $\phi dT = 0$.

To the quantity brackets on the left Helmholtz gave the name *free energy*. Representing it by F we write, at constant temperature

$$-dF = +pdv + Pos,$$

i e, the isothermal decrease of free energy is equal to the work done by the system plus a positive quantity. Since, for a reversible change, Pos = zero, the work done is then a maximum *for a given isothermal diminution of free energy*. This is known as the principle of maximum work.

The isothermal change of free energy may be greater or less than the change of energy, E, because nothing is specified as to whether heat enters or leaves the system during the isothermal change For in such a change

$$dE = dF - Td\phi \quad (dT = 0)$$

and $Td\phi (= dQ)$ may be positive or negative

If the change is made at constant temperature and constant volume $-dF = Pos$. Hence in any such change the free energy can only decrease.

If the free energy reaches a minimum value in such a change no further decrease can occur. The system (at constant temperature and volume) *must then be in equilibrium*.

In ordinary mechanics a system is in equilibrium when its potential energy is a minimum. In this more general problem where thermal changes must be allowed for this property belongs to the free energy The theorem is general, no assumption has been made in regard to the constitution of the system. Unfortunately difficulties arise in attempting to apply it excepting in the case of an *ideal gas* mixture.

For such an ideal mixture the various components of the system are independent of one another The total pressure, energy, entropy, and free energy are given by the sums of the values for the separate components

Let the constant volume and temperature be V and T, and let the contents consist of a number of gases capable of reacting according to the general law of chemical combination

$$\nu_1 A_1 + \nu_2 A_2 + \cdots = \nu_s A_s + \nu_t A_t +$$

and let them be present when in equilibrium in the proportions

$$N_1 N_2 \cdots N_s N_t \quad .$$

where the values of N are the numbers of molecules of the various kinds present It is necessary, in the first case, to calculate the free energy *per molecule* of each component.

Now reckoning from any arbitrary temperature T_0 we may write

$$E = C_v(T - T_0)$$

$$\phi = C_v \log\frac{T}{T_0} + R(\log v - \log v_0)$$

$$= C_v \log T + R\log\frac{V}{N} + k$$

where k is a constant and the other quantities are the values per molecule. Hence

$$F = C_v T + TC_v \log T + RT\log\frac{V}{N} + kT - C_v T_0$$

Since the temperature is to be treated as constant we may conveniently divide by it and write

$$F/T = C_v + C_v \log T + R\log\frac{V}{N} + k - \frac{C_v T_0}{T}$$

and for N molecules of any one kind this must be multiplied by N Now the total value of the free energy is $\sum(NF)$ and this, or its value divided by the constant T, is to be a minimum for equilibrium, *i e.*,

$$\sum \frac{1}{T}\left(F + \frac{dF}{dN}\right) dN$$

must equal zero But owing to the laws of chemical combination any changes of the quantities must satisfy the equations

$$\frac{dN_1}{\nu_1} = \frac{dN_2}{\nu_2} = \cdots - \frac{dN_s}{\nu_s} = -\frac{dN_t}{\nu_t}.$$

Hence $$\sum_{1,2,\text{etc}} \left(F + \frac{dF}{dN}\right)\nu = \sum_{s,t,\text{etc}} \left(F + \frac{dF}{dN}\right)\nu.$$

Performing the operations after dividing by T it follows that

$$\sum_{1\ 2\ \text{etc}} \left(C_v + C_v \log T + R\log\frac{V}{N} + k - \frac{C_v T_0}{T} - \frac{RN}{N}\right)\nu = \sum_{s\ t\ \text{etc}} (\quad)\nu;$$

or $$\sum_{1,2,\text{etc}} R\nu \log\frac{V}{N} = \sum_{s\ t,\text{etc}.} R\nu\log\frac{V}{N} + \text{function of } T \text{ alone};$$

or $$\log\frac{V^{\nu_1 + \nu_2 \cdots - \nu_s - \nu_t}}{N_1^{\nu_1} N_2^{\nu_2} \cdots N_s^{-\nu_s} N_t^{-\nu_t}} = \text{function of } T$$

This is the equation of chemical equilibrium at constant volume and temperature If we write $\frac{N_1}{V} = n_1$, $\frac{N_2}{V} = n_2$, etc, it becomes

$$\log\frac{n_s^{\nu_s} n_t^{\nu_t} \cdots}{n_1^{\nu_1} n_2^{\nu_2} \cdots} = \text{function of } T$$

The quantity under the logarithm sign is the equilibrium constant for constant temperature and volume If the equation in terms of N_1, N_2 etc. is examined it will be seen that when

$$\nu_1 + \nu_2 + \cdots = \nu_s + \nu_t \quad .$$

a change of volume will not disturb the equilibrium On the other hand if $\nu_1 + \nu_2 + \cdots$ is the greater sum then an increase of V will increase the values of N_1, N_2, etc and diminish those of N_s, N_t, etc

The former case would be illustrated by a reaction such as

$$\begin{matrix} H_2 + & Cl_2 \rightleftharpoons & 2HCl \\ N_1 & N_2 & N_3 \end{matrix}$$

where $\nu_1 = 1$, $\nu_2 = 1$ and $\nu_3 = 2$, and the latter case by

$$2H_2 + O_2 \rightleftharpoons 2H_2O$$

in which the $\sum(\nu)$ on the left is one greater than of the one on the right. This is stated without prejudice to the question as to whether the above reactions usually occur or not.

The function of temperature involves the specific heats (or molecular heats), which depend upon the temperature in a way undeterminable by thermodynamics, as well as the constants of integration. The values of the specific heats can however be ascertained by experiment and thus the value of the equilibrium constant at any temperature can be calculated within a constant.

Any deviation that is found from these conclusions may leave it a moot point whether the reactions are not of the specified type or whether the deviations are due to departures from the ideal gas law

The equilibrium constant was first given by Guldberg and Waage. They based it on the laws of probability of encounters between the reacting molecules. Taking the probability of an encounter of any molecule of the first with one of another kind as proportional to N_1, the probability that ν_1 of them will simultaneously collide is $N_1 N_1 N_1 N_1 \cdots$ to ν_1 terms; that is, it is $N_1^{\nu_1}$. Similarly for N_2 the required probability is $N_2^{\nu_2}$. Further the

probability that the two groups shall collide simultaneously is $N_1^{\nu_1} N_2^{\nu}$, and so on Some slight departure from the gas law is needed in order that collisions may occur at all; for if the molecules had no volume there would be nothing to collide against. But if the volume occupies a sensible proportion of the total system, corrections are required to Guldberg and Waage's law; and any attractions between the molecules, which will necessarily increase the number of collisions, necessitates still further corrections, so that this method of attacking the problem lands us in difficulties. The same is true of the thermodynamic method which has been given in detail, when other characteristic equations are employed, even the total pressure is not the sum of the "partial" pressures as it would be according to Dalton's law. The additive law breaks down also for all the other functions (E, ϕ, etc). We shall return to the problem after dealing with heterogeneous equilibria

But first some of the other properties of the free energy must be stated Since for reversible changes $dF=-\phi dT-pdv$ it follows that

$$\left(\frac{\partial F}{\partial T}\right)_v=-\phi \text{ and } \left(\frac{\partial F}{\partial v}\right)_T=-p.$$

But $$F=E-T\phi=E+T\left(\frac{\partial F}{\partial T}\right)_v.$$

Therefore $$T\left(\frac{\partial F}{\partial T}\right)_v-F=-E$$

or $$\frac{\partial}{\partial T}\left(\frac{F}{T}\right)_v=-\frac{E}{T^2}.$$

It should be noted that the *decrease* of F in a reaction is often represented by A and the corresponding *evolution* of energy (*i e.*, the heat of reaction at constant volume) by U In terms of these quantities the equation becomes

$$T\frac{\partial A}{\partial T}-A=-U$$

which is of the same form as before.

Again, since F depends, in reversible changes, only upon the state (because E, T, and ϕ so depend) it follows that

$$\frac{\partial^2 F}{\partial v\,\partial T}=\frac{\partial^2 F}{\partial T\,\partial v}$$

and therefore $$-\left(\frac{\partial\phi}{\partial v}\right)_t=-\left(\frac{\partial p}{\partial T}\right)_v.$$

Since, we can write $Td\phi=dQ$ this is identical with the equation already found, viz.:

$$\left(\frac{\partial H}{\partial v}\right)_T=l=T\left(\frac{\partial p}{\partial T}\right)_v.$$

Heterogeneous Systems.—A heterogeneous system is one in which the whole system can be divided into discrete parts each of which is homogeneous but differs from its neighbours Each is called a "phase". Without at first considering such systems in general we may take the familiar case of a vessel containing a liquid and its vapour or a solid and a liquid. These can at certain temperatures be in equilibrium with one another. Putting aside the effects of gravity and other body forces, when equilibrium exists the pressure must be uniform throughout the system for mechanical reasons, provided there is no curved interface between the phases; and the temperature must be uniform throughout for reasons depending upon conduction and radiation The values of these variables are independent of the relative amounts of liquid and vapour. Let $1-m$ and m be the masses of the two phases in a system of unit mass; and let v_1 and v_2 be their specific volumes (*i.e.*, volumes per unit mass) then the total volume is $(1-m)v_1+mv_2$. The uniform pressure is the saturation pressure; we denote it by the symbol π the value of which experiment shows to be independent of the volume but dependent upon the temperature. The total energy is $E=(1-m)E_1+mE_2$ where E_1 and E_2 are the energies per unit mass of the respective phases. The entropy is $\phi=(1-m)\phi_1+m\phi_2$. Any heat that enters may be divided into two parts corresponding to the phases it passes into. Since the law of summation obviously applies throughout we can write

$$dQ=CdT+ldV \text{ as before}$$
$$=\{(1-m)\,\sigma_1+m\sigma_2\}\,dT+ld\,\{(1-m)\,v_1+mv_2\}$$

provided, at least, that neither of the phases vanishes. Now the same considerations as before give

$$l=T\left(\frac{\partial\pi}{\partial T}\right)_v=T\frac{\partial\pi}{\partial T}$$

since π is independent of V The change of volume is $(v_2-v_1)dm$ so that the equation becomes

$$dQ=\{(1-m)\sigma_1+m\sigma_2\}dT+T(v_2-v_1)\frac{d\pi}{dT}dm.$$

The heat taken in when unit mass evaporates at constant temperature is called the latent heat of evaporation, it is equal to the coefficient of dm and is therefore

$$L=T(v_2-v_1)\frac{d\pi}{dT}$$

This is the equation of latent heat for a change of phase first given in the present form in 1850 by Clausius but actually found to be verified by experiments made in the case of the change of ice into water by Lord Kelvin in 1850 before he had accepted the law of the conservation of energy These experiments were first interpreted in terms of a calculation made by his brother James Thomson in 1849 based upon Carnot's theory of the conservation of *heat* (not energy)—the effect to be expected from lowering a quantity of heat through one degree being determined, *not by theory*, but by comparison with results obtained from Regnault's experiments on steam The lowering caused by an increase of the equilibrium pressure π by 140 atmospheres is about one degree centigrade It is a lowering in the case of ice-water because $v_{ice}>v_{water}$; it is a rise in the transition temperature (*i.e.*, the boiling point) in the case of water-steam because $v_{steam}>v_{water}$ We can conveniently take the equation in the form

$$dQ=\{(1-m)\,\sigma_1+m\sigma_2\}\,dT+Ldm$$

so that the independent variables become T and m Consider now an adiabatic change, $dQ=0$, then

$$\frac{dm}{dT}=-\frac{(1-m)\sigma_1+m\sigma_2}{L}.$$

Since the symbols σ_1, σ_2 stand for saturation values, σ_1 is positive but σ_2 *may* be negative If we write $(-\sigma_2)$ in such case for its positive numerical value we find that dm will be negative when dT is negative provided that $(1-m)\sigma_1$ is numerically less than $m(-\sigma_2)$, *i.e.*, that liquid will form in the case of water-steam when the temperature lowers Since the water deposits most readily on particles of dust, etc , in the vessel a cloud will appear. This is obviously most likely to happen when the amount of water initially present $(1-m)$ is small compared with the amount of vapour (m) In the case of a positive value for σ_2 no cloud can form

A reversible *isothermal* expansion of a mixture of water and steam always causes evaporation.

Phase Rule.—We have considered the co-existence of water and steam and of ice and water in separate phases The possibility of this co-existence is determined by the *phase rule* due to Willard Gibbs The dividing surfaces between the phases are presumed to be plane so as to exclude effects arising from surface tension. The phase rule asserts that the number of independent variations of which a system of co-existent phases is capable is $C+2-P$ where C is the number of independently variable *components* in the whole system. The term *component* must be carefully distinguished from *constituent.* Thus in dealing with water and steam, hydrogen and oxygen are constituents of each phase, but since they can only vary in chemically combining proportions it would be sufficient to specify *either* of them or even the amount of water present Thus there is only one component in this case. If free hydrogen (or oxygen) were present as well in excess there would be an additional

component and there is again an arbitrary choice as to the two components to be selected. The proof of the rule is that the system of phases is completely specified by the temperature, pressure and the data for the C components and between these $C+2$ quantities there are P independent relations (one for each phase), which characterize the system of phases.

For example, in the case of water which can exist (not necessarily co-exist) as ice, water or steam there is one component and three possible phases so that if all are present $C+2-P=0$ and there is no disposable relation—their states (defined by v and T) are absolutely fixed If only two of the phases are present $C+2-P=1$, there is therefore one relation between various values of p and T for equilibrium This relation gives the vapour pressure line or, in the case of ice and water, the connection between pressure and freezing-point. Again if there is only one phase present, there are two disposable relations, in other words the pressure and temperature can vary independently of each other. The number of disposable relations is known as the number of degrees of freedom (F) so that

$$C+2-P=F$$

When the number of phases that co-exist is the greatest possible the value of F is zero Of these phases not more than one can be gaseous because the components mix in such a phase in all proportions, so that two gaseous phases would intermingle and reduce to a single phase.

In considering the equilibrium of such a system it is necessary to introduce a new function of the variables, this is done in such a way that the independent variables become T and p. As before we have

$$Td\phi=dQ+Pos.$$

where *Pos.* stands for a positive quantity. Hence

$$dE=dQ-pdv=Td\phi-pdv-Pos.$$

Adding to both sides $d\,(pv-T\phi)$

$$d(E-T\phi+pv)=-\phi dT+vdp-Pos.$$

It follows that if the quantity in brackets on the left is calculated for the whole system its value can only decrease in any change of the system that takes place at constant pressure and temperature. Or again, if an infinitesimal change, in which p' and T are kept constant, is made about a state of equilibrium, the change on the left hand side is zero. It is sometimes called the *thermodynamic potential at constant pressure and temperature* (Duhem); or since it is concerned with the equilibrium of co-existent phases it may be called the *paraphase potential* and will be denoted by ζ.

One Component System.—Let there be one component only ($C=1$). Then if there are two phases there is one degree of freedom. There must therefore be a connection between p and T; this connection is the vapour pressure curve if the two phases are liquid and vapour Let the values of ζ per unit mass be ζ_1 for liquid and ζ_2 for the vapour. The total potential is therefore

$$\zeta=(1-m)\zeta_1+m\zeta_2.$$

Now for equilibrium

$$d\zeta=-\zeta_1dm+\zeta_2dm=0.$$

Therefore $\qquad \zeta_1=\zeta_2$

that is the potentials per unit mass are the same for the two phases. Similarly for solid and liquid

$$\zeta_o=\zeta_1$$

and for solid and vapour.

$$\zeta_o=\zeta_2.$$

These three equations specify three curves on a pT diagram. The first two curves intersect at a point given by $\zeta_2=\zeta_1=\zeta_o$. This point also satisfies all three curves. Thus the three equilibrium curves must intersect at one point This point is called the *triple point*. Further they cannot all intersect at any other common point for according to the phase rule there are no degrees of freedom when the three phases meet—the point of meeting is absolutely determinate.

Now the equations for these potentials are:

$$d\zeta_2=-\phi_2dT+v_2dp,$$

$$d\zeta_1=-\phi_1dT+v_1dp,$$

$$d\zeta_o=-\phi_odT+v_odp.$$

Whence $\qquad d(\zeta_2-\zeta_1)=-(\phi_2-\phi_1)dT+(v_2-v_1)dp=0$

for all points on the curve connecting p and T which are common to both vapour and liquid. Hence this curve is also defined by

$$\phi_2-\phi_1=(v_2-v_1)\frac{dp}{dT}.$$

The left hand side is $\dfrac{latent\ heat}{T}=\dfrac{L_{12}}{T}$.

Therefore $\qquad L_{12}=T(v_2-v_1)\dfrac{dp_{12}}{dT}$; Liquid→Vapour.

Similarly for the two other curves,

$$L_{o1}=T(v_1-v_o)\frac{dp_{o1}}{dT};\ \text{Solid}\rightarrow\text{Liquid},$$

and $\qquad L_{o2}=T(v_2-v_o)\dfrac{dp_{o2}}{dT}$, Solid→ Vapour.

These are simply Clausius equations for the three possible changes of phase.

The trigonometric tangent to the slope of any one of the p, T, curves is given by the value of $\dfrac{dp}{dT}$ for the curve, i e ,

$$\frac{dp_{12}}{dT}=\frac{\phi_2-\phi_1}{v_2-v_1},\ \frac{dp_{o1}}{dT}=\frac{\phi_1-\phi_o}{v_1-v_o}\ \text{and}\ \frac{dp_{o2}}{dT}=\frac{\phi_2-\phi_o}{v_2-v_o}.$$

Hence at the triple point these are obviously connected by the relation

$$(v_2-v_1)\frac{dp_{12}}{dT}+(v_1-v_o)\frac{dp_{o1}}{dT}+(v_o-v_2)\frac{dp_{o2}}{dT}=0$$

and therefore, at the triple point,

$$L_{o2}=L_{o1}+L_{12}.$$

This relation does not hold at any other point

It must be emphasized that in the above no assumption is made as to whether the single component is associated or not, nor whether it is equally associated in the several phases nor that the degree of association remains unchanged when the temperature changes, nor even that the matter in the phase consists of molecules. The decision in regard to such questions has no bearing on the investigations of this part of the subject. What we do assume is that each of the homogeneous phases is quite definite when the temperature and the specific volume are definitely given.

Many Components.—When there are many components in each phase the subject becomes too complicated to be dealt with in this short article. The thermodynamics potential ζ for each phase will depend upon the masses of the components as well as upon T and p. When its value is differentiated at constant temperature and pressure and equated to zero an equation is obtained of the form $\mu_1dm_1+\mu_2dm_2+\cdots=0$. The coefficients μ_1, μ_2, etc., are called the chemical potentials of the several components in the particular phase. The final result is that the chemical potential of any one component must be the same for all the phases that are coexistent. The problem of heterogeneous equilibrium in the general case would therefore be solved if only it were possible to obtain ζ as an explicit function of all the masses. This is not possible unless the ideal gas laws are assumed.

OSMOTIC PHENOMENA

When a tube has its lower end stopped by a suitable membrane and is partly full of a solution; and the lower end is dipped in pure solvent, a difference of level is often maintained in the final state of equilibrium. It is necessary that the membrane shall be permeable to the solvent but not to the solute—it shall be only *semi-permeable* in fact. If it is permeable to both, equilibrium can only be attained when the concentration on both sides has come to the same value by diffusion. Semi-permeable membranes are easily obtained that will act for months with hundreds of atmospheres difference of pressure between the two sides.

Unglazed earthenware impregnated with colloidal ferrocyanide of copper by an electrolytic method constitutes such a membrane, impermeable to sugar and many salts but permeable to water. It is only the final state of equilibrium that will be considered in this place. When all flow is over, there is a difference of pressure between the two sides of the membrane: this difference of pressure is called the *osmotic pressure*. It is, in general, a property not of the solution alone but involves the solvent also. Loose definitions based upon the properties of dilute solutions should be carefully avoided. The thermodynamical study of osmotic pressure is based upon the impossibility of obtaining external work from an isothermal reversible cycle (The efficiency of such a cycle is zero) It is possible to evaporate a unit mass of the solvent from the solute, to change its pressure so that it can then be passed *reversibly* into the liquid solvent, and finally to pass it back into the solution through the osmotic membrane. This cyclic series of operations can all be conducted isothermally and reversibly In order that the concentration shall keep constant during the changes it is necessary that the mass of the solution shall be practically infinite or that the unit mass be infinitesimal The algebra can be much simplified if a modification is made in the process Any term, representing external work done is an expression of the type $\int_1^2 pdv$. Now, integrating by parts, $\int_1^2 pdv = p_2v_2 - p_1v_1 - \int_1^2 vdp$; and for a complete cycle of changes $\sum(p_2v_2 - p_1v_1)$ must equal zero and consequently adding expressions such as pdv comes, for the whole cycle, to the same thing as adding expressions such as $\int vdp$ for the several stages The imagined process can be supposed carried out in an arrangement such as is shown in fig 1 (called by van't Hoff an equilibrium box and used by him for dilute solutions only) The solution and solvent are on opposite sides of a semi-permeable membrane C and enclosed by means of ordinary pistons A and B. Lateral cylinders are also provided with pistons; these cylinders are connected with the main cylinders by means of membranes permeable to the *vapour* alone. The solution is at a hydrostatic pressure p and any vapour in its lateral cylinder at a pressure π_p which corresponds to the particular pressure of the solution; similarly for the solvent and its vapour we have the pressures π_0 and $\pi_{o_{p_0}}$. In making these provisions it is being definitely recognized that the vapour pressure depends, not only upon the temperature but also upon the pressure of the solution or solvent (an example of this will be dealt with in connection with interfacial effects).

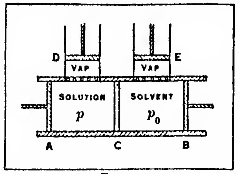

FIG. 1

The cyclic series of operations and the values of vdp corresponding to them are as follows:—(The value of $\int vdp$ in each stage is denoted by S).

i Remove unit mass (supposed infinitesimal compared with the total mass so as not sensibly to alter the concentration) of solvent from the solution by means of the lateral cylinder. Piston A requires to be moved to the right to effect this transfer. Since the pressures keep constant, $S_1 = 0$.

ii. Change the pressure of the vapour removed, from π_p to $\pi_{o_{p_0}}$: then $S_2 = \int_{\pi_p}^{\pi_{o_{p_0}}} vd\pi$ where v is the specific volume of the vapour.

iii. Pass the vapour into the solvent reversibly at constant pressure:

$$S_3 = 0.$$

iv. Pass unit mass of solvent into solution through C at constant pressures (by moving A and B suitably):

$$S_4 = 0.$$

Adding all the values of S we obtain

$$\int_{\pi_p}^{\pi_{o_{p_0}}} vd\pi = 0 \text{ whence } \pi_{o_{p_0}} = \pi_p.$$

Thus it appears that the vapour pressure of the solution when the latter is at the pressure p must equal that of the solvent when at a pressure p_0 where $p - p_0$ is the osmotic pressure It must be remembered that the standard vapour pressures as usually measured are for the cases when the liquids are at the pressures of their vapours alone.

It can easily be seen that this must be the case For if, otherwise, πp is greater than $\pi_{o_{p_0}}$ it would only be necessary to put the lateral cylinders into communication for a flow of vapour to take place from left to right This would cause fresh evaporation from the solution (to maintain the equilibrium value of vapour pressure) and (for a similar reason) condensation of vapour into the solvent. Since the evaporation from the solution would increase the concentration a flow through C from the solvent would take place to maintain the equilibrium This action would go on unceasingly and a particular kind of perpetual motion would be obtained. Unless we are prepared to admit the possibility of this type of perpetual motion, we must deny the assumption of any difference between the vapour pressures of the solvent and solution when measured under equilibrium conditions for the two *liquids*. That the vapour pressure of a pure liquid must depend upon the hydrostatic pressure was first shown by Sir William Thomson (Lord Kelvin). If a vertical capillary tube be placed in water, *e g*, under the bell jar of an air pump so that the air can be removed, the water stands in the tube at a higher level than outside by the amount h where $g\rho h = 2\sigma/r$, ρ = density of the liquid, σ the surface tension and r the radius of the tube. (*See* SURFACE TENSION) Now the vapour constitutes an atmosphere and between the inside and outside levels there is a difference of vapour pressure of $g\rho' h$ approximately where ρ' is the density of the vapour Now the essential difference between the liquid inside and out is that at the upper level inside it is at a less hydrostatic pressure than outside (equilibrium being maintained by the effects of the curvature of the surface).

$$\text{Hence} \qquad \frac{d\pi}{dp} = \frac{g\rho' h}{g\rho h}$$

$$= \frac{\rho'}{\rho} \text{ approximately.}$$

It is easy to show that this is not approximate merely but exact for a pure liquid. In the case of a solution however it requires modification (Porter, *Roy Soc. Proc.* A. 79, p 519 [1907]) To examine the case of a solution enclose a large volume V of solution in a cylinder, under pressure, fitted with a lateral chamber such as on the left of fig. 1 replacing the membrane C by a solid base. Conduct a cyclic series of operation as follows:—

i. Remove unit mass of vapour at constant pressure by means of the lateral cylinder: the volume of the solution diminishes by s (say) and the vapour increases by v:

$$S_1 = 0.$$

ii. Compress the vapour removed and the solution to new *equilibrium* values·

$$S_2 = \int_p^{p'} (V - s)\, dp + \int_{\pi_p}^{\pi_{p'}} vd\pi.$$

iii Pass the removed vapour back into the solution at constant pressure for each:

$$S_3 = 0.$$

iv. Compress solution by restoring the original pressure:

$$S_4 = \int_{p'}^{p} Vdp$$

If these changes are conducted isothermally and reversibly they must add to zero Hence

$$\int_{\pi_p}^{\pi_{p'}} vd\pi = \int_p^{p'} sdp \text{ exactly.}$$

Since this is true, however small the change of pressure, we can write it in the differential form

$$d\pi/dp = \frac{s}{v}$$

or more precisely (owing to the fact that all the quantities depend upon the pressures)

$$\frac{d\pi_p}{dp} = \frac{s_p}{v_\pi}.$$

The quantity s stands for the shrinkage of the volume of the solution when unit mass of solvent is removed from it, the unit mass being so small (or the volume so large) that no sensible change of concentration occurs. Combining this result with the proved fact that in the state of equilibrium $\pi_p = \pi_{o p_o}$ we can obtain an expression for the osmotic pressure, $p - p_o$. For, employing the integral form, the limits being from the standard values of the vapour pressures to the equilibrium values of the pressures

$$\int_{\pi_\pi}^{p} s dp = \int_{\pi_\pi}^{\pi_p} v d\pi \quad \text{and} \quad \int_{\pi_{o\pi_o}}^{p_o} u dp_o = \int_{\pi_{o\pi_o}}^{\pi_{o p_o}} v d\pi,$$

where π_π and $\pi_{o\pi_o}$ are the standard vapour pressures Subtracting these, we obtain an exact equation for the osmotic pressure

$$\int_{\pi_\pi}^{p} s dp - \int_{\pi_{o\pi_o}}^{p_o} u dp_o = \int_{\pi_\pi}^{\pi_p} v d\pi + \int_{\pi_{o p_o}}^{\pi_{o\pi_o}} v d\pi = \int_{\pi_\pi}^{\pi_{o\pi_o}} v dp$$

because $\pi_p = \pi_{o p_o}$.

From this equation simpler approximate equations can be deduced to fit particular cases

The equality in the equilibrium vapour pressures may be shown in another way. In fig. 2 is represented a domed chamber separated into two portions: in the lower part, by a membrane semi-permeable to solvent *liquid;* in the upper part, by one semi-permeable to solvent vapour. The lower part contains solution and solvent on the opposite sides of the membrane, the upper part contains, besides the vapour, sufficient air on each side to make up the total pressures to p and p_o respectively If the pressures due to the vapours are not equal it is easily seen as before that a *perpetuum mobile* will be set up

It ought to be added that, in the exact equation for the osmotic pressure, there is no assumption as to the molecular state in either the liquid or vapour phases. Any influence that the degree of association or dissociation may have is all taken into account by the numerical values that can be found by direct experiment for u, s, and the standard vapour pressures. When the approximate equation is used, the values of R and u (or s) both refer to unit mass and there is no reference to molecules If we consider (so-called) molecular values by multiplying u, s, and R by such a factor that R becomes the universal value of the gas constant it may be presumed that this multiplier is at least an approximation to the molecular weight of the vapour in *the vapour state* but still no information is obtained as to the molecular state of either solvent or solute in the liquids. Such information as we have concerning molecular states is obtained by the aid of gas theory as distinct from thermodynamics.

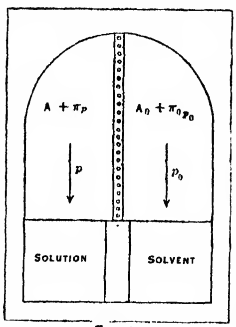

FIG 2

General Use of Semi-permeable Membranes.—Imaginary semi-permeable membranes are made great use of in theoretical investigations, as in the above case. Doubt has often been raised as to the validity of this procedure at any rate in those cases for which no real membrane of the kind has been manufactured. We know that such membranes are obtainable in certain cases, *e g.*, hot silica ("fused quartz") transmits helium and not nitrogen, hot cast iron transmits hydrogen; indiarubber is permeable to carbon dioxide. The curved surface to a liquid maintains a difference of pressure between the interior and exterior and thereby acts as a membrane semi-permeable to the *vapour;* and between a solution and the liquid solvent, as it has been already stated, very perfect membranes can be obtained. In reality, in order to employ the thermodynamical argument, it is unnecessary that it should be possible to make any such membrane. Clerk Maxwell introduced the idea of "demons" instructed to let very fast molecules pass through an opening and stop the slow ones, thereby increasing the effective temperature on one side of a partition and diminishing that on the other In this way he was able to show that the second law of thermodynamics does not hold for individual molecules but only for matter in the bulk In like manner we may suppose a row of good demons turning back all the sugar molecules and letting the water molecules through in such a way that the average distribution of the water molecules in the solvent region is maintained in equilibrium Such a row of demons will be doing precisely what our semi-permeable membrane is supposed to do and the average force per unit area they exert (viz $p - p_o$) corresponds exactly to the osmotic pressure. It should be noted that it is not exactly equal to the pressure the sugar molecules would exert if they were a gas with its molecules equally crowded, because there is a differential effect due to the difference of density of the water on the two sides, but in dilute solutions it is not far from this value. The most unsympathetic view that is permissible in connection with the use of membranes is that they provide a picturesque way of carrying out the virtual displacements of concentrations, etc , which are employed in the applications of the thermodynamic potentials to equilibrium problems

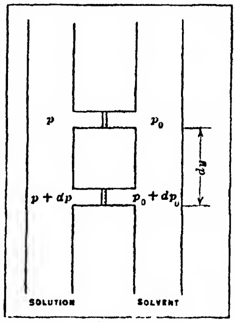

FIG. 3

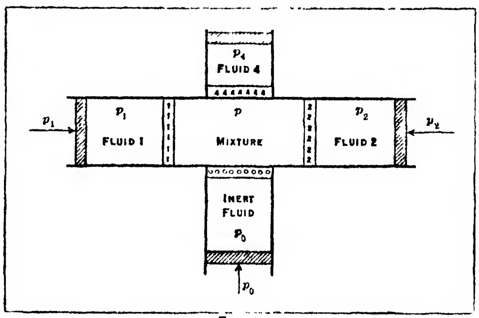

FIG. 4

Effect of Gravity.—We can apply the membrane method to the effect of gravity in producing a gradient of concentration with the depth in a solution. Columns of solution and solvent are connected across through semi-permeable membranes at two levels distant dy apart (fig 3). The densities being ρ and ρ_o we have, on the solution side, $dp = g\rho dy$ where dy is positive when measured downwards and, on the solvent side, $dp_o = g\rho_o dy$ so that $d(p - p_o) = g(\rho - \rho_o)dy$. But $p - p_o$ is the osmotic pressure, P, so the equation gives $dP/dy = g(\rho - \rho_o)$ or $dP/dp = \frac{\rho - \rho_o}{\rho}$.

If we differentiate, with respect to p, the exact equation for the osmotic pressure the result is $sdp = udp_0$

or
$$\frac{d(p-p_0)}{dp} = \frac{u-s}{s}.$$

This differs from the above value, but the value just given is the variation when the concentration is kept constant; the other is the total variation. In fact we can write

$$\frac{dP}{dp} = \frac{\partial P}{\partial p} + \frac{\partial P}{\partial c} \cdot \frac{dc}{dy}$$

where c is the concentration (measured in any convenient way); i e,

$$\frac{p-p_0}{p} = \frac{u-s}{s} + \frac{\partial P}{\partial c} \cdot \frac{dc}{dy}.$$

For dilute solutions $\frac{\partial p}{\partial c}$ follows nearly the gas law. If its exact value is known, either in consequence of this law or from experiment, the value of dc/dy can be determined. This result is of wide application There is no assumption that it is limited to true solutions. Applied to a gamboge suspension it gives Perrin's Law of the distribution with depth when the concentration is small, and allows also a calculation to be made of the very great deviations from Perrin's Law of distribution when the concentration is great (*Trans. Far. Soc.* XVIII. [1922]; XIX. [1923], XXI, 63, 66 [1925]).

Application of Membranes to Homogeneous Equilibrium.—An interesting application can be made of semi-permeable membranes to determine the equilibrium constant for homogeneous equilibrium Fig. 4 indicates the kind of equilibrium box required The equilibrium which is taken as the type is that for which the chemical equation is

$$\nu_1 A_1 + \nu_2 A_2 \rightleftharpoons \nu_3 A_3 + \nu_4 A_4;$$

and in addition an inert gas is supposed to be present, indicated by A_0; this takes no part in the reaction but modifies the total pressure of the mixture By appropriate movement of the semi-permeable membranes a cycle of changes is carried on leading eventually to the equation

$$\nu_1 \int^{p_1} u_1 dp_1 + \nu_2 \int^{p_2} u_2 dp_2 - \nu_3 \int^{p_3} u_3 dp_3 - \nu_4 \int^{p_4} u_4 dp_4$$
$$= \text{function of the temperature alone}$$

This reduces to the mass action law when gas values are inserted For detailed information in regard to its derivation reference must be made to the original paper (*Trans Far Society*, 1919) Since the membranes may be made permeable to the *vapours* of the respective components the values of u and p may be taken to stand for the specific volumes (or molecular volumes) and pressures of these vapours.

Duhem-Margules Equation.—This information is in part supplied for condensed systems by a theorem put forward by Duhem in 1887 and subsequently interpreted by Margules (1895). By means of an equilibrium box similar to that in fig. 4 we can produce the series of changes indicated in fig 5 The case of a homogeneous mixture of two components will be considered so that only two lateral cylinders are needed Fig 5 consists of three diagrams, one for each separated vapour and one for the liquid mixture. It should be mentioned that from a theoretical

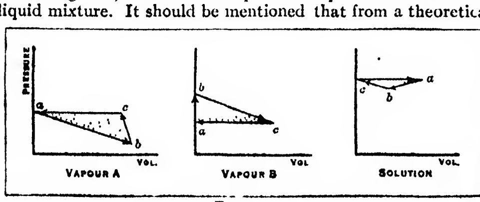

FIG. 5

point of view (thermodynamically) there is no difference between a solution and a mixture, at least, a mixture of molecular type (coarse emulsions must be excluded). Again, the operations must be isothermal and reversible. The presence of each component in the mixture lowers the vapour pressure of the other component. Throughout each change the pressure in the lateral chambers must be perpetually maintained in equilibrium with the mixture by suitably moving the pistons. The detailed changes are as follows:

i. Remove a definite fraction, say fn_1 of the molecules n_1 in the mixture. The pressure in A cylinder goes down along ab, that of B goes up—in both cases because the relative concentration of B is increased—along ab (on the B diagram) The mixture also changes along ab.

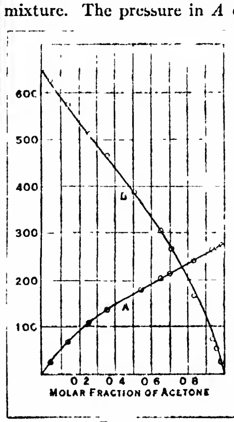

FIG. 6

ii. Remove the *same fraction* fn_2 of the molecules of B. The pressure in B goes down along bc (on B diagram) and that of A goes up along bc (on A diagram); and that of the mixture changes along bc (on the third diagram). The solution is now of the same concentration as at first and consequently the pressures at c must in each chamber be the same as at first, *i e.*, as at a.

iii Lastly return the vapours in A and B to the mixture adjusting the rates of transfer so that the concentration of the mixture remains constant. The changes in the three diagrams are in each case along ca and the original state is restored.

We will neglect the changes of volume of the solution because, for usual cases they are exceedingly small compared with the vapour changes The total work done is the difference of the areas of the triangles on A and B; or

$$fn_1 v_1 \frac{\partial \pi_1}{\partial n_1} + fn_2 v_2 \frac{\partial \pi_2}{\partial n_1}$$

and this sum must equal zero. So far we might have considered masses instead of numbers of molecules (for the problem has nothing essential to do with molecules) We can now put $\pi v_1 = n_1 RT$ and $\pi_2 v_2 = n_2 RT$, where R is the same for both The values of n_1 must now mean the numbers of molecules in the mixture reckoned as of the same constitution (*i e*, either single or double molecules, etc.) as in the *vapour* state, and similarly for n_2. So that

$$\frac{n_1}{\pi_1}\frac{\partial \pi_1}{\partial n_1} + \frac{n_2}{\pi_2}\frac{\partial \pi_2}{\partial n_1} = 0.$$

The differential coefficients are partials, the value of n_2 being constant during the change represented We can usefully represent the concentrations by molar fractions, that is, $\mu_1 = n_1/(n_1+n_2)$ and $\mu_2 = n_2/(n_1+n_2)$ so that $\mu_1 + \mu_2 = 1$

When this is done the equation becomes

$$\frac{\mu_1}{\pi_1}\frac{d\pi_1}{d\mu_1} + \frac{\mu_2}{\pi_1}\frac{d\pi_2}{d\mu_1} = 0$$

or
$$\mu_1 \frac{d}{d\mu_1} \log\pi_1 = \mu_2 \frac{d}{d\mu_2} \log\pi_2$$

since $d\mu_2 = -d\mu_1$. The advantage of the transformation to molar fractions is that the equation has been reduced to a symmetrical form the right hand being the same function of μ_2 that the left is of μ_1. This is the Margules-Duhem equation. It is not quite exact because the *vapours* have been treated as ideal gases and the changes of the volume of the mixture have been neglected. For practical purposes, however, it is probably very much more accurate than experiments require. The implication of the equation is that each side of it *must be the same symmetrical* function of μ_1 and μ_2; *i.e.*, it must be of the form $f(\mu_1\mu_2)$ and this must be the *same* for both vapours. Unfortunately the law imposes no further restriction upon this function so that an endless number

of cases can arise. Suitable simple values for the functions are 1, $\mu_1\mu_2$, $\mu_1^2\mu_2^2$, etc., each of which may be multiplied by an arbitrary constant and any number of terms may be taken simultaneously. For any such function the equation can be integrated and it takes the form

$$\log\frac{\pi_1}{\Pi_1}=\alpha\log\mu_1+\beta\mu_2^2+\gamma\mu_2^2(1+3\mu_1)\text{ etc.}$$

and $$\log\frac{\pi_2}{\Pi_2}=\alpha\log\mu_2+\beta\mu_1^2+\gamma\mu_1^2(1+3\mu_2)\text{ etc.}$$

where Π_1 and Π_2 are the vapour pressures of the pure components and the constants α, β, γ, etc must be the same for both. If the first term on the right is sufficient we have

$$\frac{\pi_1}{\Pi_1}=\mu^{\alpha 1}=\left(\frac{n_1}{n_1+n_2}\right)^{\alpha}=\left(1-\frac{n_2}{n_1+n_2}\right)^{\alpha}\doteq 1-\frac{\alpha n_2}{n_1+n_2}$$

when n_2 is small.

This is practically Raoult's law when allowance is made for dissociation. In very many cases two terms are necessary and α is often unity. The equation then becomes

$$\log\frac{\pi_1}{\Pi_1\mu_1}=\beta\mu_2^2.$$

In fig. 6 the curves for a mixture of acetone and ether are given. The value of β was determined from one point on the acetone curve but it fits equally well the curve for either. The base line gives the molar % of acetone when read from left to right but it equally well gives the percentage of ether when read from right to left. The experimental points were determined by J. Sameshima (*Amer. J. of Sc.* XL , 1482, 1918). Examination of the equation shows that in this group of examples there is only one parameter, viz : β. In fig. 7 the shapes of the curves are shown for different values of β, the ordinates being π/Π Examples can be found for many values of β For sulphuric acid and water $\beta=-0{\cdot}6$ except for dilute solutions, when a more complicated formula is necessary Fig 8 gives the case of gold in mercury. In this example four terms are required. If the base line is read from left to right the curve is the vapour pressure for mercury, if the base line is read from right to left the curve gives the vapour pressure (though exceedingly small) of gold in mercury. In both cases these are the values of π_1, π_2 which require to be inserted in the equations for the constant of homogeneous equilibrium. The central part of the curve, which slopes downward, is easily shown to be in an unstable region. Where the curve is horizontal (towards the right of the figure) is the concentration at which the equilibrium becomes unstable; in other words it represents the *saturation* concentration of the solution of gold. The vapour pressure of the *gold* should at that point be the same as that of pure gold and that is seen to be the case by examining the curve reversed. Calcium chloride in water also requires four terms; curves are shown on fig 9 for this case at two temperatures.

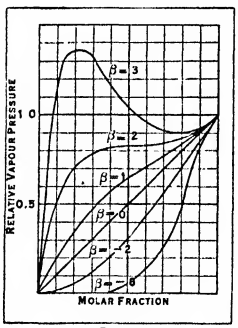

FIG 7

Taking these cases as examples there is little likelihood of the vapour pressures required for the calculation of the equilibrium constant being determinable by any *a priori* method and resort must be made to direct experiment—at any rate for the determination of a few typical values from which the constants can be deduced. Further information can be found in *Trans. Far. Soc.* 15, 1920; 24, 344, 405, 543 (1928). In the first of these papers a general form of equation is developed for three or more components.

Interfacial Effects.—In considering equilibrium the interface between any two phases was considered as being plane. It is only if it is plane that the pressure is uniform over the whole system. There is a change of pressure on crossing the boundary equal to $\sigma\left(\frac{1}{R_1}+\frac{1}{R_2}\right)$ where σ is the surface tension and R_1 and R_2 are the radii of curvature in any two mutually rectangular planes. (*See* SURFACE TENSION.) The pressure is greater on the concave side (as in a soap bubble.) We have seen that it increases the vapour

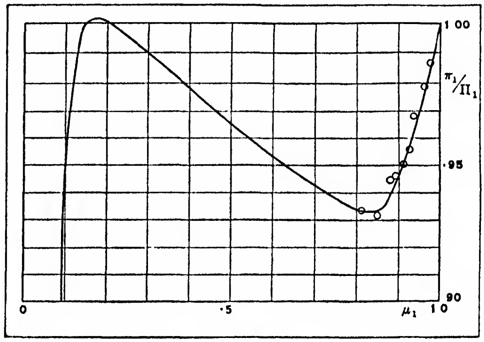

FIG. 8

pressure if convex outwards; it increases the density also and, indeed, it may be expected to change all the properties which depend upon these. For example, the position of the triple point is shifted when either the liquid or the solid phase has curved boundaries. An equivalent change of pressure produced in any way has the same effect. As a matter of fact, the independent atmosphere of air acting in addition to the vapour pressure on ice and water shifts the triple point from ·0075° C to exactly zero. It clearly must do so because the ice water line under the pressure

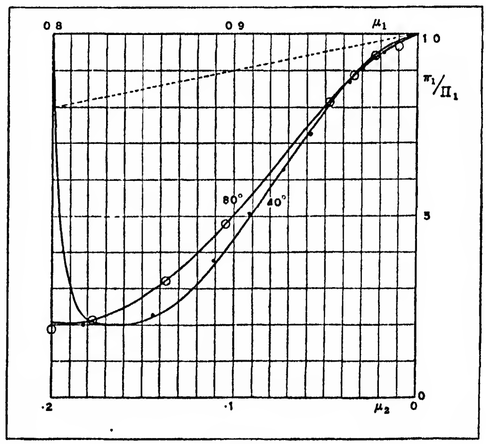

FIG. 9

of one atmosphere goes through 0° C, and not ·0075° C and the triple point lies on this line. (*Phil. Mag.* XXIX., 143, 1915.)

There is another effect at the interface which is present even if this surface is plane. Consider a solution in equilibrium with its vapour. The presence of the solute either increases or diminishes the surface tension; for most salts it is an increase, for many organic substances such as oils, soaps, etc., it is a decrease; and the change is greater the greater the amount of the solute. Now the existence of surface tension is a demonstration of the possession by a surface lamina of more potential energy than a

lamina in the body of the phase. The tendency being for the potential energy to take the lowest possible value, solute (being free to be displaced) will move toward the surface lamina or away from it according to which change will diminish the surface tension. In strictness therefore, the two phases are not delimited by mathematically sharp boundaries: there is an intervening lamina whose structure depends upon both phases and is different from that in the body of either. This subject was first studied in detail by Willard Gibbs. Following him, we replace the actual distribution of material by a *uniform* distribution in each phase and superimpose upon this an *extra* distribution (which may be negative) representing the excess per unit area of any component in this superficial lamina. This excess is called the surface concentration and is usually denoted by σ. When a surface tension is measured experimentally it is the value as modified by the surface layer which is actually determined. One effect of this non-uniform distribution of the solute is that when the solute tends to lower the surface considerably, small traces of it added to the pure solvent are sufficient to produce very considerable lowering. In fig. 10, the curve shows the change of surface tension with the amount of soap added to the solute. An amount of soap equal to a concentration of 0.2% produces a lowering to practically the same value as for a concentrated solution and a great part of this reduction is produced by the first traces of soap that are added and go almost completely to the surface layer.

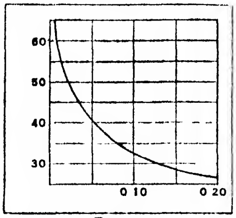

FIG. 10

Willard Gibbs investigated thermodynamically the "surface-concentration" to be expected. External work is done not only in expansion of volume (pd) but also in the extension of the surface area ($-\sigma dA$). Hence $dE = Td\phi - \pi dV + \sigma dA$ for reversible changes or $d(E - T\phi + \pi V) = -\phi dT + Vd\pi + \sigma dA$. Since $E - T\phi + \pi V$ depends only upon the state

$$\left(\frac{\partial V}{\partial A}\right)_\pi = \left(\frac{\partial \sigma}{\partial \pi}\right)_A$$

Representing quantities for the liquid and vapour phases with suffixes 1 and 2 respectively, we have $dV_2 = \frac{RT}{\pi} dN_2$ where V_2 is the volume of the vapour, π the vapour pressure and N_2 the number of molecules in the vapour. In the liquid let n_1 equal *total* number of molecules of the solute and N_1 those of the solvent in the solution. Imagine a virtual displacement from the liquid to vapour phase at constant temperature and concentration produced by an extension of the area. For unit increase of area n_1 changes by $-\frac{dn_1}{dA}$; and for the concentration to keep constant $\frac{dn_1}{n_1} = \frac{dN_1}{N_1}$ so that dN_1 molecules of solvent evaporate. But $dN_2 = -dN_1 = -\frac{N_1}{n_1} dn_1$. The change of volume dV is practically dV_2 (*i.e.*, neglecting change of volume of the liquid).

Hence
$$\left(\frac{\partial V}{\partial A}\right)_\pi = -\left(\frac{RTN_1 dn_A}{n\pi dA}\right)_\pi$$

Again
$$\left(\frac{\partial \sigma}{\partial \pi}\right)_A = \left(\frac{\partial \sigma}{\partial n} \cdot \frac{dn}{d\pi}\right)_A = -\frac{N_1}{\pi}\left(\frac{\partial \sigma}{\partial n}\right)_A$$

in which an approximate value of the change of π with n has been inserted. Hence finally

$$\frac{dn_A}{dA} = \Gamma = -\frac{n}{RT}\frac{d\sigma}{dn}$$

where n_A are the *excess* molecules of solute in unit surface layer. This is a maximum value for Γ, since more exact expressions for the vapour pressure tend to reduce it. For strong solutions of sugar the simple expression goes up to four times the more exact value; but for dilute solutions it must be very near the truth.

THERMAL EFFECTS

The thermal changes that take place in the case of dilution of solutions can be examined in a similar way to other latent heats. If we enclose a solution and the solvent on opposite sides of an osmotic membrane in an "equilibrium box" it is easy to carry out a Carnot cycle of changes for which the efficiency is $\frac{dT}{T}$. We deduce, for the reversible latent heat of dilution corresponding to unit mass of solvent entering, the expression,

$$H_{\text{reversible}} = T\left(s\frac{dp}{dT} - u\frac{dp_0}{dT}\right) \text{ exactly}$$

For the corresponding change of energy we must subtract the external work done, viz.: $sdp - udp_0$, whence

$$\Delta E = s\left(T\frac{dp}{dT} - p\right) - u\left(T\frac{dp_0}{dT} - p_0\right)$$

This latter must be very nearly the irreversible heat absorbed on stirring solvent into the solution instead of through an osmotic membrane, because in the stirring process, the whole being at ordinary pressure, there is very little external work done and the latent heat is practically the energy change. When p_0 is small throughout,

$$H_{\text{reversible}} \text{ is practically } Ts\frac{dP}{dT}$$

and
$$\Delta E \text{ is practically } s\left(T\frac{dP}{dT} - P\right)$$

where P is the osmotic pressure. Connecting P with the vapour pressure by the usual substitution $Ps = RT\log\frac{\pi_0}{\pi_\pi}$,

$$\Delta E = T^2 s\frac{\partial}{\partial T}\left(\frac{R}{s}\log\frac{\pi_0}{\pi_\pi}\right)$$

and, if s and R are independent of temperature, this becomes the same as an approximate equation given by Kirchhoff. If this irreversible heat of dilution is zero, $\log\frac{\pi_0}{\pi_\pi}$ must be independent of temperature.

This approximate law is known as von Babo's law.

Freezing Points.—When a solution is in equilibrium with the solid phase of the solvent it is at its freezing point, and must have the same vapour pressure as the solid. Different solutions in the same solvent must have the same freezing points if their vapour pressures (and therefore their osmotic pressures) are the same.

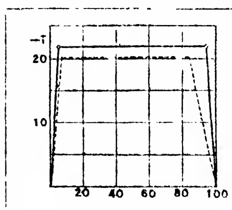

FIG. 11

Cryohydric Points.—If, at the freezing point, the solution of one is saturated it is then at a cryohydric point. A solution of common salt is at the point at about $-22°$ C.

Freezing mixtures depend upon the fact that if salt be added to ice it will dissolve and cool the system owing to the latent heat of solution. By adding fresh salt further cooling goes on until the solution becomes saturated at the final temperature reached. The effect of adding various quantities is shown in fig. 11. The experimental curve (dotted) differs from the curve, calculated from an approximate theory, mainly owing to the thermal capacity of the containing vessel. It will be seen that the relative proportions of ice and salt may be varied within wide limits and the cryohydric temperature will be approached. When the material cooled by the mixture has considerable thermal capacity the greatest chance of producing the lowest temperature is when

the amount of salt is about 30 per cent.

Irreversible Processes.—Owing to the universality of frictional forces every process that we can conduct is in reality irreversible Trains require to be driven even on the level, ocean waves subside and winds cease soon after the cause producing them has ceased to be effective The motion of the piston of an engine allows the steam to be set in motion and the kinetic energy that corresponds is ultimately transformed into molecular energy and is mainly unavailable for doing useful work. It is true that so far as a difference of temperature is set up by friction *some* of the temperature energy may be transferred into work but the amount is incommensurable with the loss

The most typically irreversible process is that in which a fluid is forced through a nozzle or a porous plug Considering the steady state of adiabatic flow only, we have (i) an equality of the mass leaving and entering the plug, (ii) an equality of the energy leaving and entering. The energy is in part the intrinsic energy E (per unit mass) and in part energy of motion in bulk, $\frac{1}{2}$ velocity squared (per unit mass). Further the incoming fluid does work p_1v_1 in forcing the fluid through and the outgoing fluid does work p_2v_2 in forcing out the fluid in front of it; the gain of energy on this account is $p_1v_1-p_2v_2$ Hence the total gain of energy inside the plug is

$$E_1+p_1v_1+\tfrac{1}{2}V_1^2-(E_2+p_2v_2+\tfrac{1}{2}V_2^2)$$

and in the steady adiabatic state of flow this is zero. We assume that the two positions at which the energies are reckoned are well outside the plug so that we can consider the velocity, etc , as uniformly distributed across the cross section When the 'narrows' inside the throttle or plug are reached the velocity attains a high value and a high viscous resistance is met with so that even V_2 may be small in spite of the great difference of pressure on the two sides and further dissipation of energy takes place in the eddies that form on emergence The result is that the fluid is much hotter on emergence than if it had expanded between the same extreme pressures reversibly and adiabatically in a cylinder. We suppose for simplicity only a small difference of pressure, etc , so that

$$d(E+pv)=-d(\tfrac{1}{2}V^2).$$

If the motion has been *linear* and *without friction* it is known from hydrodynamics that

$$d(\tfrac{1}{2}V^2)=-vdp$$

so that the equation would reduce to

$$dE+pdv=0,$$

which as we know represents the heat entry in a reversible process To consider such a process would be equivalent, for example, to discussing the oscillation of a frictionless pendulum. Such a pendulum would go on vibrating without loss of amplitude for ever and every half period it would perfectly reverse its path The lack of reversibility of a real pendulum is entirely due to its meeting with frictional resistance to its motion. The loss of kinetic energy on the average is represented by the extra temperature of the bob and air, together with the energy which is radiated out. This 'loss' of energy of visible motion corresponds to an increase in the internal energy of the system such as would be caused by an entry of heat from outside and it produces the same effects Similarly in the problem of the flow of fluid if we add the frictional heat dq to the actual value of $d(\frac{1}{2}V^2)$ it may be expected by the law of conservation to give $-vdp$. Hence

$$d(E+pv)=-d(\tfrac{1}{2}V^2)=-vdp+dq$$

or

$$dE+pdv=dq.$$

Hence the actual value of the change on the left side is precisely the same as it would be if heat dq had entered *reversibly from outside the system.* In reality no heat has entered from outside but the frictional heat produces precisely the same effect as if it had done so. The essential difference between the two cases is that if we were to reverse the reversible system the corresponding heat would be *given out;* but the frictional heat is always positive in whichever sense the transformation proceeds. Since dq produces the same effects as if it had come from outside reversibly it must increase the entropy by the amount dq/T although the change is really adiabatic so far as the whole system is concerned. This can be illustrated by supposing the fluid to be an ideal gas. In such a case the increase of entropy is $C_v\log\frac{T_2}{T_1}+R\log\frac{v_2}{v_1}$. But

$$dE=C_vdT \text{ and } pv=RT;$$

hence

$$d(E+pv)=(C_v+R)\,dT.$$

Neglecting $d(\frac{1}{2}V^2)$, as we can do when the flow is slow (because it depends upon the square of V and the other changes are of the first order of small quantities), this must be zero, i e., $dT=0$; so that no change of temperature occurs. Hence $T_2=T_1$ and $\phi_2-\phi_1=R\log\frac{v_2}{v_1}$. Further $v_2>v_1$ because $p_1>p_2$. So there is a positive increase of entropy, and its value is $R\log\frac{v_2}{v_1}=-\frac{1}{T}\int vdp$ as we inferred it to be Since $E+pv$ (which is called the *enthalpy*) is a quantity which depends only upon the state we can calculate it for *any* change (adiabatic or otherwise) between the extreme states. It is most convenient to calculate it for a reversible change (which may not be adiabatic) Starting from

$$dq=dE+pdv$$
$$d(E+pv)=dq+vdp$$
$$=C_pdT-T\left(\frac{\partial v}{\partial T}\right)_p dp+vdp$$

Hence if $E+pv$ has the same value as at first the right hand must also be zero or

$$\left(\frac{dT}{dp}\right)_{E+pv}=\frac{T(\partial v/\partial T)_p-v}{C_p}.$$

The left hand side is the amount the temperature falls in the plug experiment for unit fall of pressure It will be zero (as it is for a perfect gas) provided that

$$T\left(\frac{\partial v}{\partial T}\right)_p-v=0$$

or (by integration) $\qquad v=Tf(p),$

where $f(p)$ stands for *any* function of the pressure. Kelvin and Joule found experimentally that at moderate pressures air and carbon dioxide cool in the process while hydrogen warms In reality all fluids (gaseous or liquid) at certain temperatures and pressures undergo neither warming nor cooling in the process. At sufficiently high or sufficiently low temperatures all get hotter, in an intermediate region of temperatures they *may* get cooler but they fail to do so if the pressure is above a certain limit which appears to be at about 15 times the critical pressure (*Trans. Far. Soc., Discussion on the production and utilization of cold.* President's opening remarks, 1922)

General.—The conclusions drawn from thermodynamics can be confirmed and extended by the aid of the principles generalized in mechanics which enable problems to be approached from a different aspect. The two fields of enquiry overlap. The thermodynamical way ignores the precise mechanism of the various transformations: making use of principles which are independent of the particular mechanism. This does not exclude the possibility of information being obtained in other ways which are not as independent of it and by which it may ultimately be possible to formulate with some degree of precision the nature of that mechanism. Such methods are of course less abstract in the picture with which they present us but enormous difficulties are met with in dealing even with the simpler phenomena.

It is possible to examine the movements of the hands of a watch and to detect and discuss certain regularities of their movement; but it is another matter to predict (without taking the watch to pieces) what the precise mechanism inside may be. The problems that are met with in chemical and other reactions are much more complicated than the movements of the hands of the watch. It is only very gradually that an imperfect picture is being created. Such help as is being given it by statistical me-

chanics is exceedingly valuable; but it is outside the scope of this article.

BIBLIOGRAPHY.—The fundamental reference is to the collected papers of R Clausius, translated into English by W. R. Browne as *The mechanical theory of heat* (1879). In addition the following are the most important. Bertrand, *Thermodynamique* (1887); Duhem, *Traité élémentaire de méchanique chimique*, four volumes. Duhem, *Le potential thermodynamique et ses applications à la méchanique chimique* (1895), etc. (this is a more elementary treatise); J. Willard Gibbs, *Collected Papers*, 2 vols, especially the paper on Heterogeneous equilibrium (an edition published in 1928 includes his treatise on *Statistical Mechanics* which was previously published separately); Max Planck, *Treatise on thermodynamics* (translated by A Ogg) (3rd ed, 1927); O. Sackur, *Lehrbuch der Thermochemie und Thermodynamik* (1917) (and especially the English translation by Gibson which contains a large amount of additional matter). (A. W. Po)

THERMOMETRY, the art of measuring temperature or degree of heat (Gr. θερμός warm; μέτρον, a measure). The instruments used for this purpose are known as thermometers, or sometimes, when the temperatures to be measured are high, as pyrometers.

A brief sketch of the evolution of the thermometer is included in the article HEAT. The object of the present article is to discuss the general principles on which the accurate measurement of temperature depends, and to describe the application of these principles to the construction and use of the most important types of thermometer Special attention will be devoted to more recent advances in scientific methods of testing thermometers and to the application of electrical and optical methods to the difficult problem of measuring high temperatures.

Zero: Fundamental Interval.—In all systems of measuring temperature it is necessary (1) to choose a zero or starting-point from which to reckon, (2) to determine the size of the degree by subdividing the interval between two selected fixed points of the scale (called the "fundamental interval") into a given number of equal parts. The fundamental interval selected is that between the temperature of melting ice and the temperature of condensing steam, under standard atmospheric pressure. On the Centigrade system the fundamental interval is divided into 100 parts, and the melting-point of ice is taken as the zero of the scale We shall denote temperature reckoned on this system by the letter t, or by affixing the letter C. It is often convenient to reckon temperature, not from the melting-point of ice, but from a theoretical or absolute zero representing the lowest conceivable temperature. We shall denote temperature reckoned in this manner by the letter T, or θ, or by affixing the letters *Abs*. In practice, since the absolute zero is unattainable, the absolute temperature is deduced from the Centigrade temperature by adding a constant quantity, T_0, representing the interval between the absolute zero and the melting-point of ice; thus $T=t+T_0$

Arbitrary Scales.—An arbitrary scale can be constructed by selecting any physical property of a substance which varies regularly with the temperature, such as the volume of a liquid, or the pressure or density of a gas, or the electrical resistance of a metal. Thus if V denote the volume of a given mass at the temperature t, and if V_0, V_1 represent the volumes of the same mass at the temperatures 0° and 100° C, the size of 1° C on the scale of this arbitrary thermometer is one hundredth part of the fundamental interval, namely $(V_1-V_0)/100$, and the temperature t at volume V is the number of these degrees contained in the expansion $V-V_0$ between 0° and t° C. We thus arrive at the formula

$$t=100(V-V_0)/(V_1-V_0) \qquad (1)$$

which is the general expression for the temperature Centigrade on any such arbitrary scale, provided that we substitute for V the particular physical property selected as the basis of the scale. If we prefer to reckon temperature from an arbitrary zero defined by the vanishing of V, which may conveniently be called the *fundamental zero* of the scale considered, we have, putting V=0 in equation (1), the numerical values of the fundamental zero T_0, and of the temperature T reckoned from this zero

$$T_0=100V_0/(V_1-V_0), \text{ and } T=T_0V/V_0=t+T_0. \qquad (2)$$

It is frequently convenient to measure temperature in this manner when dealing with gases.

Absolute Scale.—It is necessary for theoretical purposes to reduce all experimental results as far as possible to the absolute scale, defined as explained in HEAT, on the basis of Carnot's principle, which is independent of the properties of any particular substance. This scale can be most nearly realized in practice by observing the temperature on the scale of a gas-thermometer, and making special experiments on the gas to determine how far its scale deviates from that of the thermodynamical engine. In the case of the gases hydrogen and helium, which can exist in the liquid state only at very low temperatures, the deviations from the absolute scale at ordinary temperatures are so small that they cannot be determined with certainty. Thermometers containing these gases are generally taken as the ultimate standards of reference in practical thermometry.

International Temperature Scale.—The experimental difficulties incident to the realization of the thermodynamic scale have made it expedient to adopt a practical scale designated as the International Temperature Scale This scale has been proposed as the result of discussion extending over a considerable period between the national laboratories of Germany, Great Britain, and the United States, and has been adopted provisionally by the Seventh General Conference of Weights and Measures, meeting in Paris in 1927 It is intended to represent the thermodynamic scale as closely as is possible with present knowledge for scientific and industrial purposes, and may be subject to revision as more accurate methods of measurement are evolved. It is based on a number of fixed and reproducible equilibrium temperatures to which numerical values are assigned, and upon the indications of interpolation instruments calibrated according to a specified procedure at the fixed temperatures A summary of the basic fixed points, and of the procedure to be adopted in realizing the practical scale, will be given at the end of this article

MERCURIAL THERMOMETRY

Mercurial thermometers will doubtless continue to be employed for the majority of measurements for which they are suited, especially in cases where facility of observation is more important than the highest attainable degree of precision. It is to be presumed, however, that the indications of such instruments will be reduced when necessary to the international scale by comparison with a suitable standard instead of being expressed in terms of the mercurial scale as previously defined The somewhat exacting process of the calibration of the bore of a standard mercurial thermometer, which was essential to the reproduction of the mercurial scale, becomes of secondary importance, since the calibration correction of each instrument will be automatically included in the table of corrections supplied by the testing laboratories Other corrections depend on the conditions under which the instrument is used.

Correction for Changes of Zero.—The *changes of zero* are of two kinds: (*a*) *Secular rise* of zero due to gradual recovery from changes or strains acquired by the bulb during the process of manufacture This process may be hastened and subsequent changes practically eliminated by annealing the bulb after manufacture, and before final adjustment, at a high temperature, such as that of boiling sulphur (about 450° C). A thermometer which has not been so treated may show a rise of zero amounting to as much as 20° or 30° when exposed for some time to a temperature of 350° C. (*b*) *Temporary depression* of zero after each exposure to a high temperature, followed by a slow recovery which may last for days or weeks The best thermometers of hard glass show a depression of zero amounting to about one-tenth of 1° C after exposure to 100° C In softer glass the depression is usually greater and more persistent, and may amount to half a degree after 100° C. At higher temperatures the depression generally increases roughly as the square of the temperature above 0° C. It may amount to 2° or 3° at 300° C. The effect cannot be calculated or predicted in any series of observations because it depends in so complicated a manner on the past history and on the time. It is a most serious difficulty in accurate mercurial thermometry, especially at high temperatures The most satisfactory method of correction appears to be to observe the zero

immediately after each reading, and to reckon the temperature from the variable zero thus observed. The rationale of this procedure is that the depression is produced at the high temperature much more rapidly than the subsequent recovery at the low temperature The thermometer is taken from the bath and allowed to cool rapidly by free exposure to the air As soon as it reaches 40° or 50° C, it is plunged in the melting ice, and the lowest point reached is taken as the temporary zero.

The following formulae have been proposed by various observers to represent the depression of zero for different kinds of glass —

$$\left.\begin{array}{l} \text{Pernet, French } \textit{cristal},\ dz=0{\cdot}0040(t/100)^2 \\ \text{Guillaume, } \textit{Verre dur},\ 0-100^\circ\text{ C},\ dz=(8886t+10{\cdot}84t^2)\,10^{-7} \\ \text{Bottcher, } \textit{Cristal dur},\ 0-190^\circ\text{ C},\ dz=(7970t+329t^2)\,10^{-7} \\ \quad\text{,,}\quad \text{Jena, 16, III.},\ dz=(7100t-8t^2)\,10^{-7}\ . \end{array}\right\} \quad (3)$$

The symbol dz in these formulae stands for the depression of zero produced by an exposure to a temperature t The depression is about three times as large in French crystal as in English flint glass, and varies roughly as the square of t. *Verre dur* and Jena, 16, iii., are varieties of hard glass chosen as standards in France and Germany respectively, on account of the comparatively small depression of zero to which they are liable. At low temperatures, up to 50° C, the depression is very nearly proportional to t, but at temperatures above 100° C it is necessary to adopt another formula in which the term depending upon t^2 is more important These formulae are useful as giving an idea of the probable size of the correction in any case, but they cannot be employed in practice except in the simplest cases and at low temperatures On account of these temporary changes of zero, a mercury thermometer intended for the most accurate work at ordinary temperatures (as in calorimetry) should preferably never be heated above 40° or 50° C, and certainly never above 100° C Above 100° C the changes of zero become more irregular and more variable, depending on the rate of cooling and on the sequence of previous observations, so that even if the method of observing the zero after each reading is adopted, the order of precision attainable rapidly diminishes

Correction of the Fundamental Interval.—The thermometer to be tested is exposed to steam condensing at atmospheric pressure in an apparatus which is often called a "hypsometer," constructed with double walls to protect the inner tube containing the thermometer from any cooling by radiation The standard atmospheric pressure at which the temperature of the steam is by definition equal to 100° C is equivalent to that produced by a column of mercury 760 millimetres high, having a density of 13·5951 $p/_{cm^3}$, at a place where the acceleration of gravity is 980 665 $cm/_{sec^2}$., giving a pressure equal to 1,013,250 $dyn/_{cm^2}$. The atmospheric pressure at the time of observation is reduced to these units by applying the usual corrections for temperature and gravitation If the pressure is near 760 mm , the temperature of the steam may be deduced by assuming that it increases at the rate of 1° C for 27·2 mm of pressure The following approximate formula for the temperature t of steam in terms of pressure p in mm. has been adopted for the range between 680 and 780 mm.

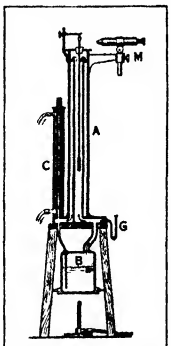

FIG. 1.—HYPSOMETER

$$t=100+0{\cdot}0367(p-760)-0{\cdot}000023(p-760)^2. \qquad (4)$$

A convenient type of hypsometer is shown in fig. 1. The boiler B is separate from the steam-jacket A surrounding the thermometer. A gauge G is provided for indicating the steam pressure (difference from atmospheric) and a condenser C for returning the condensed steam to the boiler The thermometer is observed by the microscope M.

If the barometer has a brass scale correct at 0° C, and p be the reading in millimetres, the correction for temperature is made approximately by subtracting 0·00163 p mm.

If L is the latitude and M the height of the station in metres above the sea-level, the correction for gravitation is approximately made by subtracting (0 0026 cos 2L+0·0000002M) p

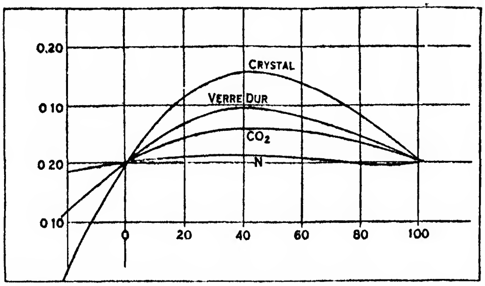
The zero of the thermometer is observed immediately after the steam point. If n be the interval in degrees of the scale between the two observations, and if t_1 be the temperature of the steam, the fundamental interval of the thermometer may be taken as 100 n/t_1, provided that t_1, is nearly 100° C. Since all the readings of a thermometer have to be corrected for the error of the fundamental interval, by dividing by the fundamental interval thus observed and multiplying by 100, it is a matter of some convenience in practice to have the instrument graduated so that the difference between the readings in ice and at 100° C is very nearly 100° of the stem. The correction can then be applied as a small percentage independently of the other corrections. The method of determining the fundamental interval above described applies to all other kinds of thermometers, except that it is not generally necessary to observe the zero *after* the steam point. The temperature of the steam t_1 should be expressed in the scale of the thermometer tested, if the scale differs appreciably from that of Regnault.

Pressure Correction.—The corrections for variations of internal and external pressure on the bulb are of some importance in accurate thermometry, but can be applied with considerable certainty at moderate temperatures. The correction for external pressure is assumed to be proportional to the change of pressure, and to be independent of the temperature. It is generally determined by enclosing the thermometer to be tested in a vessel of water, and observing the change of reading produced by varying the pressure. The correction is generally between one and two thousandths of a degree per centimetre of mercury change of pressure, but must be determined for each thermometer, as it depends on the nature of the glass and on the form and thickness of the walls of the bulb The coefficient of the correction for internal pressure is greater than that for external pressure by the difference between the compressibility of mercury and that of glass, and may be calculated from it by assuming this relation. If b_0, b_1, are the external and internal coefficients, expressed in degrees of temperature per centimetre of mercury, we have the relation

$$b_1=b_0+0{\cdot}00015,\ \text{degrees per cm. of mercury.} \qquad (5)$$

The coefficient of internal pressure can also be determined by taking readings in the horizontal and vertical positions when the thermometer is at some steady temperature such as that of ice or steam. The reading of the thermometer is generally reduced to an external pressure of one standard atmosphere, and to an internal pressure corresponding to the horizontal position. It is also possible to include the internal pressure correction in the scale correction, if the thermometer is always read in the vertical position. In addition to the variations of internal pressure due to the column of mercury in the stem, there are variations due to capillarity. The internal pressure is greater when the mercury is rising than when it is falling, and the reading is depressed to an extent depending on the fineness of the bore and the thinness of the walls of the bulb. The capillary pressure does not depend only on the bore of the tube, but also apparently to an even greater extent on the state of the walls of the tube. The least trace of dirt on the glass or on the mercury is capable of producing capillary pressures much greater than would be calculated from the diameter of the tube. Even in the best thermometers, when there are no inequalities of bore sufficient to account for the observed variations, it is seldom found that the mercury runs equally easily in all parts of the stem. These variations of capillary pressure are somewhat capricious, and set a limit to the order of accuracy attainable with the mercury thermometer. It appears that the difference of reading of a good thermometer between a rising and falling meniscus may amount to five or ten thousandths of a degree. The difference may be reduced by continuous tapping, but it is generally best to take readings always on a rising column, especially as the variations in the angle of contact, and therefore in the capillary pressure, appear to be much smaller for the rising meniscus. In ordinary work the zero reading and the steam reading would both generally correspond to a falling meniscus; the former necessarily,

the latter on account of the phenomenon of the temporary depression of zero, which causes the thermometer to read higher during the first moments of its exposure to steam than it does when the expansion of the bulb has reached its limit. It is easy to secure a rising meniscus at the steam point by momentarily cooling the thermometer. At the zero point the meniscus generally begins to rise after five or ten minutes The question, however,



FROM "PHILOSOPHICAL TRANSACTIONS" BY COURTESY OF ROYAL SOCIETY

FIG 2 —DIFFERENCES BETWEEN SCALES OF MERCURY, AND GAS THERMOMETERS AND HYDROGEN SCALE, ACCORDING TO GUILLAUME AND CHAPPUIS

is not of much importance, as the error, if any, is regular, and the correction for capillarity is necessarily uncertain

Stem-exposure Correction.—When the bulb of a mercury thermometer is immersed in a bath at a temperature t, and a part of the column of mercury having a length of n degrees is exposed to a lower temperature t_2, the reading of the thermometer will be lower by $a \times n \times (t-t_2)$ degrees (nearly) than it would have been if the whole of the mercury and stem had been at the temperature t The factor a in this expression is the apparent coefficient of expansion of mercury in glass, and varies from ·000150 to ·000165 for different kinds of glass In order to apply this correction, it is usual to observe t_2 by means of an auxiliary "stem-thermometer" with its bulb placed near the middle of the emergent column n Occasionally stem-thermometers with long thin bulbs are employed to give more nearly the average temperature of the whole emergent column Owing to conduction along the stem of the thermometer, and to heated vapours near the bath, the mean temperature determined in this manner is generally too low To allow for this empirically, an arbitrary reduction is often made in the value taken for n or a, but this cannot be regarded as satisfactory for work of precision The only practical method of reducing the correction is to limit the number of degrees n exposed, or, in other words, to work with thermometers of "limited range" Each of these thermometers must then be corrected by comparison with a standard thermometer free from stem-exposure correction, such as a platinum-resistance thermometer. To secure results of any value the correction must be determined at each point under the actual conditions of observation under which the thermometer is to be used. In work of precision it is necessary to use ten or twenty thermometers to cover a range of 300°, as this is the only method of securing an open scale and reasonable accuracy as regards stem-exposure.

GAS THERMOMETRY

The deviations of the gas thermometer from the absolute scale are so small that this instrument is now universally regarded as the ultimate standard in thermometry. It had, in fact, already been adopted for this purpose by Regnault and others, on a priori considerations, before the absolute scale itself had been invented. Although the indications of a gas thermometer are not absolutely independent of the changes of volume of the envelope or bulb in which the gas is contained, the effect of any uncertainty in this respect is minimized by the relatively large expansibility of the gas. The capricious changes of volume of the bulb, which are so great a difficulty in mercurial thermometry, are twenty times less important in the case of the gas thermometer. As additional reasons for the choice we have the great simplicity of the laws of gases, and the approximate equality of expansion and close agreement of the thermometric scales of all gases, provided that they are above their critical temperatures Subject to this condition, at moderate pressures and provided that they are not dissociated or decomposed, all gases satisfy approximately the laws of Boyle and Charles These two laws are combined in the characteristic equation of the gaseous state, viz, $pv = RT$, in which p is the pressure and v the volume of unit mass of the gas in question, and R is a constant which varies inversely as the molecular weight of the gas, and is approximately equal to the difference of the specific heats

Practical Conditions and Methods.—In practice it is not convenient to deal with unit mass, but with an arbitrary mass M occupying a space V, so that the specific volume $v = V/M$. It is also necessary to measure the pressure p in terms of mercury columns, and not in absolute units The numerical value of the constant R is adjusted to suit these conditions, but is of no consequence in thermometry, as we are concerned with ratios and differences only The equation may be written in the form $T = pV/RM$, but in order to satisfy the essential condition that T shall be a definite function of the temperature in the case of a gas which does not satisfy Boyle's law exactly, it is necessary to limit the application of the equation to special cases which lead to definite, but not necessarily identical, thermometric scales There are three special cases of practical importance, corresponding to three essentially distinct experimental methods.

Volumetric Method (constant-pressure)—In this method V is variable and p and M are constant This method was employed by Gay-Lussac, and is typified in the ideal thermometer with reservoir of variable capacity designed by Lord Kelvin. It corresponds to the method ordinarily employed in the common liquid-in-glass thermometer, but is not satisfactory in practice, owing to the difficulty of making a bulb of variable and measurable volume the whole of which can be exposed to the temperature to be measured

Manometric Method (constant-volume or density)—In this method p is variable and V and M are constant Variations of temperature are observed and measured by observing the corresponding variations of pressure with a mercury manometer, keeping a constant mass, M, of gas enclosed in a volume, V, which is constant except for the unavoidable but small expansion of the material of which the bulb is made.

Gravimetric Method (constant-pressure)—In this method M is variable and p and V are constant This method is generally confounded with (i) under the name of the constant-pressure method, but it really corresponds to the method of the weight thermometer, or the "overflow" method, and is quite distinct from an experimental standpoint, although it leads to the same thermometric scale In applying this method, the weight M of the vapour itself may be measured, as in Regnault's mercury-vapour thermometer, or in Deville and Troost's iodine-vapour thermometer. The best method of measuring the overflow is that of weighing mercury displaced by the gas The mass of the overflow may also be estimated by observing its volume in a graduated tube, but this method is much less accurate

In addition to the above, there are mixed methods in which both p and V or M are variable, such as those employed by Rudberg or Becquerel; but these are unsatisfactory for precision, as not leading to a sufficiently definite thermometric scale. There is also a variation of the constant-volume method (ii), in which the pressure is measured by the volumetric compression of an equal mass of gas kept at a constant temperature, instead of by a manometer.

Construction of Apparatus.—The manometric or constant-volume method was selected by Regnault as the standard, and has been most generally adopted since his time. His apparatus has not been modified except in points of detail. A description of his instrument will be found in most text-books on heat.

A simple and convenient form of the instrument for general use is Jolly's (described in Poggendorff's *Jubelband*, p. 82, 1874), and represented in fig. 3. The two vertical tubes of the manometer

are connected by an india-rubber tube properly strengthened by a cotton covering, and they can be made to slide vertically up and down a wooden pillar which supports them; they are provided with clamps for fixing them in any position and a tangent screw for fine adjustment The connection between the bulb and the manometer is made by means of a three-way tap. The scale of the instrument is engraved on the back of a strip of plane mirror before silvering, and the divisions are carried sufficiently far across the scale for the reflections of the two surfaces of the mercury to be visible behind the scale. Parallax can thus be avoided and an accurate reading obtained without the necessity of using a cathetometer In order to allow for the expansion of the glass of the reservoir a weight-thermometer bulb is supplied with the instrument, made from another specimen of the same kind of glass, and the relative expansion of the mercury and the glass can thus be determined by the observer himself The volume of the air-bulb and that of the capillary tube and the small portion of the manometer tube above the small beak of glass, the point of which serves as the fiducial mark, are determined by the instrument-makers The improvements introduced by Chappuis, of the International Bureau at Sèvres, in the construction of the constant-volume hydrogen thermometer selected by the committee for the determination of the normal scale, are described in the text-books (*e g*, Watson's *Physics*).

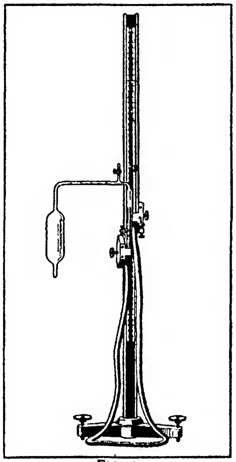


FIG 3

Pressure Correction.—In the practical application of the manometric method there are certain corrections peculiar to the method, of which account must be taken in work of precision. The volume of the bulb is not accurately constant, but varies with change of pressure and temperature. The thermal expansion of the bulb is common to all methods, and will be considered in detail later The pressure correction is small, and is determined in the same manner as for a mercury thermometer. The value so determined, however, does not apply strictly except at the temperature to which it refers If the pressure-coefficient were constant at all temperatures and equal to e, the pressure correction, dt, at any point t of the scale would be obtainable from the simple formula

$$dt = ep_0t(t-100)/T_2 \qquad (6)$$

where p_0 is the initial pressure at the temperature T_2 But as the coefficient probably varies in an unknown manner, the correction is somewhat uncertain, especially at high temperatures Another very necessary but somewhat troublesome correction is the reduction of the manometer readings to allow for the varying temperatures of the mercury and scale. Since it is generally impracticable to immerse the manometer in a liquid bath to secure certainty and uniformity of temperature, the temperature must be estimated from the readings of mercury thermometers suspended in mercury tubes or in the air near the manometer It is therefore necessary to work in a room specially designed to secure great constancy of temperature, and to screen the manometer with the utmost care from the source of heat in measurements of high temperature

Stem-exposure.—In all gas thermometers it is necessary in practice that the part of the gas in contact with the mercury or other liquid in the manometer should not be heated, but kept at a nearly constant temperature. The space above the mercury, together with the exposed portion of the capillary tube connecting the manometer with the thermometric bulb, may be called the "dead space." If the volume of the dead space is kept as nearly as possible constant by adjusting the mercury always up to a fixed mark, the quantity of air in this space varies nearly in direct proportion to the pressure, *i.e.*, in proportion to the temperature of the thermometric bulb at constant volume. This necessitates the application of a stem-exposure correction, the value of which is approximately given by the formula

$$dt = rt(t-100)/T_2 \qquad (7)$$

where r is the ratio of the volume of the dead space to the volume of the thermometric bulb, and T_2 is the mean temperature of the dead space, which is supposed to be constant. The magnitude of the correction is proportional to the ratio r, and increases very rapidly at high temperatures If the dead space is 1 per cent of the bulb, the correction will amount to only one-tenth of a degree at 50° C, but reaches 5° at 445° C, and 30° at 1,000° C It is for this reason important in high-temperature work to keep the dead space as small as possible and to know its volume accurately. With a mercury manometer, the volume is liable to a slight uncertainty on account of changes of shape in the meniscus, as it is necessary to use a wide tube in order to secure accurate measurements of pressure

It is possible to avoid this difficulty, and to make the dead space very small, by employing oil or sulphuric acid or other non-volatile liquid to confine the gas in place of mercury (*Phil Trans*, A. 1887, p 171). The employment of a liquid which wets the tube makes it possible to use a much smaller bore, and also greatly facilitates the reading of small changes of pressure At the same time the instrument may be arranged so that the dead space correction is automatically eliminated with much greater accuracy than it can be calculated This is effected as shown diagrammatically in fig 4, by placing side by side with the tube AB, connecting the bulb B to the manometer A, an exact duplicate CD, closed at the end D, and containing liquid in the limb C, which is of the same size as the branch A of the manometer and in direct communication with it The tube CD, which is called the compensating tube, contains a constant mass of gas under exactly similar conditions of volume and temperature to the tube AB. If therefore the level of the liquid is always adjusted to be the same in both tubes AB and CD, the mass of gas contained in the dead space AB will also be constant, and is automatically eliminated from the equations, as they contain differences only

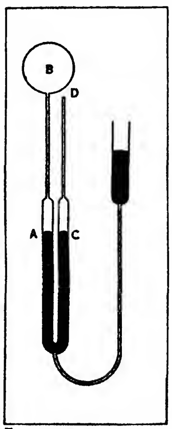

FIG 4—METHOD OF COMPENSATION

Gravimetric Method.—In the writer's opinion, the gravimetric or overflow method, although it has seldom been adopted, and is not generally regarded as the most accurate, is much to be preferred to the manometric method, especially for work at high temperatures It is free from the uncertain corrections above enumerated as being peculiar to the manometric method The apparatus is much simpler to manipulate and less costly to construct. If the pressure is kept constant and equal to the external atmospheric pressure, there is no strain of the bulb, which is particularly important at high temperatures There is no dead space correction so long as the temperature of the dead space is kept constant The troublesome operation of reading and adjusting the mercury columns of the manometer is replaced by the simpler and more accurate operation of weighing the mercury displaced, which can be performed at leisure. The uncertain correction for the temperature of the mercury in the manometer is entirely avoided

The reasons which led Regnault to prefer the constant-volume thermometer are frequently quoted, and are generally accepted as entirely conclusive, but it is very easy to construct the constant-pressure or gravimetric instrument in such a manner as to escape the objections which he urges against it.

Compensated Differential Gas Thermometer.—The chief

advantage of the gravimetric method, which Regnault and others appear to have missed, is that it is possible to make the measurements altogether independent of the atmospheric pressure and of the observation of mercury columns. This is accomplished by using, as a standard of constant pressure, a bulb S, fig. 5, containing a constant mass of gas in melting ice, side by side with the bulb M, in which the volume of the overflow is measured. The pressure in the thermometric bulb T is adjusted to equality with the standard by means of a delicate oil-gauge G of small bore, in which the difference of pressure is observed by means of a cathetometer microscope This kind of gauge permits the rapid observation of small changes of pressure, and is far more accurate and delicate than the mercury manometer. The fundamental measurement of the volume of the overflow in terms of the weight of mercury displaced at o° C involves a single weighing made at leisure, and requires no temperature correction. The accuracy obtainable at ordinary temperatures in this measurement is about ten times as great as that attainable under the best conditions with the mercury manometer At higher temperatures the relative accuracy diminishes in proportion to the absolute temperature, or the error dt increases according to the formula

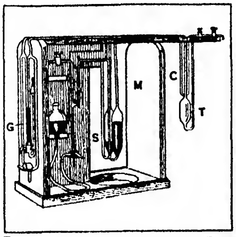

FIG 5—COMPENSATED DIFFERENTIAL GAS THERMOMETER

$$dt/t = -(T/T_o)dw/w, \tag{8}$$

where w is the weight of the overflow and dw the error This diminution of the sensitiveness of the method at high temperatures is commonly urged as a serious objection to the method, but the objection is really without weight in practice, as the possible accuracy of measurement is limited by other conditions. So far as the weighing alone is concerned, the method is sensitive to one-hundredth of a degree at 1,000° C, which is far beyond the order of accuracy attainable in the application of the other corrections.

Method of Using the Instrument—A form of gas thermometer constructed on the principles above laid down, with the addition of a duplicate set of connecting tubes C for the elimination of the stem-exposure correction by the method of automatic compensation already explained, is shown in fig 5.

In setting up the instrument, after cleaning, and drying and calibrating the bulbs and connecting tubes, the masses of gas on the two sides are adjusted as nearly as possible to equality, in order that any changes of temperature in the two sets of connecting tubes may compensate each other. This is effected with all the bulbs in melting ice, by adjusting the quantities of mercury in the bulbs M and S and equalizing the pressures The bulb T is then heated in steam to determine the fundamental interval. A weight w_1 of mercury is removed from the overflow bulb M in order to equalize the pressures again If W is the weight of the mercury at o° C which would be required to fill the bulb T at o° C, and if $W+dW_1$ is the weight of mercury at o° which would be required to fill a volume equal to that of the bulb in steam at t_1, we have the following equation for determining the coefficient of expansion a, or the fundamental zero T_o,

$$at_1 = t_1/T_o = (w_1+dW_1)/(W-w_1) \tag{9}$$

Similarly if w is the overflow when the bulb is at any other temperature t, and the expansion of the bulb is dW, we have a precisely similar equation for determining t in terms of T_o, but with t and w and dW substituted for t_1 and w_1 and dW_1. In practice, if the pressures are not adjusted to exact equality, or if the volumes of the connecting tubes do not exactly compensate, it is only necessary to include in w a small correction dw, equivalent to the observed difference, which need never exceed one part in ten thousand.

It is possible to employ the same apparatus at constant volume as well as at constant pressure, but the manipulation is not quite so simple, in consequence of the change of pressure. Instead of removing mercury from the overflow bulb M in connection with the thermometric bulb, mercury is introduced from a higher level into the standard bulb S so as to raise its pressure to equality with that of T at constant volume The equations of this method are precisely the same as those already given, except that w now signifies the "inflow" weight introduced into the bulb S, instead of the overflow weight from M. It is necessary, however, to take account of the pressure-coefficient of the bulb T, and it is much more important to have the masses of gas on the two sides of the apparatus equal than in the other case The thermometric scale obtained in this method differs slightly from the scale of the manometric method, on account of the deviation of the gas compressed at o° C from Boyle's law, but it is easy to take account of this with certainty.

Another use to which the same apparatus may be put is the accurate comparison of the scales of two different gases at constant volume by a differential method. It is usual to effect this comparison indirectly, by comparing the gas thermometers separately with a mercury thermometer, or other secondary standard But by using a pair of bulbs like M and S simultaneously in the same bath, and measuring the small difference of pressure with an oil-gauge, a higher order of accuracy may be attained in the measurement of the small differences than by the method of indirect comparison.

Expansion Correction.—In the use of the mercury thermometer we are content to overlook the modification of the scale due to the expansion of the envelope, which is known as Poggendorff's correction, or rather to include it in the scale correction In the case of the gas thermometer it is necessary to determine the expansion correction separately, as our object is to arrive at the closest approximation possible to the absolute scale. It is a common mistake to imagine that if the rate of expansion of the bulb were uniform, the scale of the apparent expansion of the gas would be the same as the scale of the real expansion—in other words, that the correction for the expansion of the bulb would affect the value of the coefficient of expansion $1/T_o$ only, and would be without effect on the value of the temperature t deduced. A result of this kind would be produced by a constant error in the initial pressure on the manometric method, or by a constant error in the initial volume on the volumetric method, or by a constant error in the fundamental interval on any method, but *not* by a constant error in the coefficient of expansion of the bulb, which would produce a modification of the scale exactly analogous to Poggendorff's correction The correction to be applied to the value of t in any case to allow for any systematic error or variation in the data is easily found by differentiating the formula for t with respect to the variable considered Another method, which is in some respects more instructive, is the following:—

Let T be the function of the temperature which is taken as the basis of the scale considered, then we have the value of t given by the general formula (1), already quoted in § 3 Let dT be the correction to be added to the observed value of T to allow for any systematic change or error in the measurement of any of the data on which the value of T depends, and let dt be the corresponding correction produced in the value of t, then substituting in formula (1) we have,

$$t+dt = 100(T-T_o+dT-dT_o)/(T_1-T_o+dT_1-dT_o),$$

from which, provided that the variations considered are small, we obtain the following general expression for the correction to t,

$$dt = (dT-dT_o)-(dT_1-dT_o)t/100 \tag{10}$$

It is frequently simpler to estimate the correction in this manner, rather than by differentiating the general formula

In the special case of the gas thermometer the value of T is given by the formula

$$T = pV/RM = pV/R(M_o-M_2), \tag{11}$$

where p is the observed pressure at any temperature t, V the volume of the thermometric bulb, and M the mass of gas remaining in the bulb. The quantity M cannot be directly observed, but is deduced by subtracting from the whole mass of gas M_o con

tained in the apparatus the mass M_2 which is contained in the dead space and overflow bulb In applying these formulae to deduce the effect of the expansion of the bulb, we observe that if dV is the expansion from 0° C. and V_o the volume at 0° C, we may write

$$V=V_o+dV,\ T=p(V_o+dV)/RM=(pV_o/RM)\ (1+dV/V_o),$$

whence we obtain approximately

$$dT=TdV/V_o \qquad (12)$$

If the coefficient of expansion of the bulb is constant and equal to the fundamental coefficient f (the mean coefficient between 0° and 100° C), we have simply $dV/V_o=ft$; and if we substitute this value in the general expression (14) for dt, we obtain

$$dt=(T-T_1)ft=ft(t-100) \qquad (13)$$

Provided that the correction can be expressed as a rational integral function of t, it is evident that it must contain the factors t and $(t-100)$, since by hypothesis the scale must be correct at the fixed points 0° and 100° C, and the correction must vanish at these points It is clear from the above that the scale of the gas thermometer is not independent of the expansion of the bulb even in the simple case where the coefficient is constant The correction is by no means unimportant. In the case of an average glass or platinum reservoir, for which f may be taken as 0·000025 nearly, the correction amounts to $-0·0625°$ at 50° C, to 3·83° at 445° C, and to 22 5° at 1,000° C

The value of the fundamental coefficient f can be determined with much greater accuracy than the coefficient over any other range of temperature The most satisfactory method is to use the bulb itself as a mercury weight thermometer, and deduce the cubical expansion of the glass from the absolute expansion of mercury as determined by Regnault. Unfortunately the reductions of Regnault's observations by different calculators differ considerably even for the fundamental interval The values of the fundamental coefficient range from 00018153 Regnault, and ·00018210 Moss, to ·00018257 Chappuis The extreme difference represents an uncertainty of about 4 per cent. (1 in 25) in the expansion of the glass This uncertainty is about 100 times as great as the probable error of the weight thermometer observations. But the expansion is even less certain beyond the limits of the fundamental interval. Another method of determining the expansion of the bulb is to observe the linear expansion of a tube or rod of the same material, and deduce the cubical expansion on the assumption that the expansion is isotropic It is probable that the uncertainty involved in this assumption is greater in the case of glass or porcelain bulbs, on account of the difficulty of perfect annealing, than in the case of metallic bulbs

Except for small ranges of temperature, the assumption of a constant coefficient of expansion is not sufficiently exact. It is therefore usual to assume that the coefficient is a linear function of the temperature, so that the whole expansion from 0° C may be expressed in the form $dV=t(a+bt)V_o$, in which case the fundamental coefficient $f=a+100b$. Making this substitution in the formula already given, we obtain the whole correction

$$dt=(f+bT)t(t-100). \qquad (14)$$

It will be observed that the term involving b becomes of considerable importance at high temperatures. Unfortunately, it cannot be determined with the same accuracy as f, because the conditions of observation at the fixed points are much more perfect than at other temperatures Provided that the range of the observations for the determination of the expansion is co-extensive with the range of the temperature measurements for which the correction is required, the uncertainty of the correction will not greatly exceed that of the expansion observed at any point of the range. It is not unusual, however, to deduce the values of b and f from observations confined to the range 0° to 100° C, in which case an error of 1 per cent., in the observed expansion at 50° C, would mean an error of 60 per cent. at 445°, or of 360 per cent at 1,000° C. (Callendar, *Phil. Mag* December 1899) Moreover, it by no means follows that the average value of b between 0° and 100° C should be the same as at higher or lower temperatures. The method of extrapolation would therefore probably lead to erroneous results in many cases, even if the value could be determined with absolute precision over the fundamental interval. It is probable that this expansion correction, which cannot be reduced or eliminated like many of the other corrections which have been mentioned, is the chief source of uncertainty in the realization of the absolute scale of temperature at the present time The uncertainty is of the order of one part in five or ten thousand on the fundamental interval, but may reach 0 5° at 500° C, and 2° or 3° at 1,000° C.

Thermodynamical Correction.—Of greater theoretical interest, but of less practical importance on account of its smallness, is the reduction of the scale of the gas thermometer to the thermodynamical scale. The deviations of a gas from the ideal equation $pv=R\theta$ may be tested by a variety of different methods, which should be employed in combination to determine the form of the characteristic equation The principal methods by which the problem has been attacked are the following:—

(1) By the comparison of gas thermometers filled with different gases or with the same gas at different pressures (employing both gravimetric and manometric methods) the differences in their indications are observed through as wide a range of temperature as possible Regnault, employing this method, found that the differences in the scales of the permanent gases were so small as to be beyond the limits of accuracy of his observations. Applying greater refinements of measurement, Chappuis and others have succeeded in measuring small differences, which have an important bearing on the type of the characteristic equation They show, for instance, that the equation of van der Waals, according to which all manometric gas thermometers should agree exactly in their indications, requires modification to enable it to represent the behaviour of gases even at moderate pressures

(2) By measuring the pressure and expansion coefficients of different gases between 0° and 100° C the values of the fundamental zero (the reciprocal of the coefficient of expansion or pressure) for each gas under different conditions may be observed and compared The evidence goes to show that the values of the fundamental zero for all gases tend to the same limit, namely, the absolute zero, when the pressures are indefinitely reduced The type of characteristic equation adopted must be capable of representing the variations of these coefficients.

(3) By observing the variations of the product pv with pressure at constant temperature the deviations of different gases from Boyle's law are determined Experiment shows that the rate of change of the product pv with increase of pressure, namely $d(pv)/dp$, is very nearly constant for moderate pressures such as those employed in gas thermometry This implies that the characteristic equation must be of the type

$$v=F(\theta)/p+f(\theta) \qquad (15)$$

in which $F(\theta)$ and $f(\theta)$ are functions of the temperature only to a first approximation at moderate pressures The function $F(\theta)$, representing the limiting value of pv at zero pressure, appears to be simply proportional to the absolute temperature for all gases. The function $f(\theta)$, representing the defect of volume from the ideal volume, is the slope of the tangent at $p=0$ to the isothermal of θ on the pv, p diagram, and is sometimes called the "angular coefficient." It appears to be of the form $b-c$, in which b is a small constant quantity, the "co-volume," of the same order of magnitude as the volume of the liquid, and c depends on the cohesion or co-aggregation of the molecules, and diminishes for all gases continuously and indefinitely with rise of temperature This method of investigation has been very widely adopted, especially at high pressures, but is open to the objection that the quantity $b-c$ is a very small fraction of the ideal volume in the case of the permanent gases at moderate pressures, and its limiting value at $p=o$ is therefore difficult to determine accurately.

(4) By observing the cooling effect $d\theta/dp$, or the ratio of the fall of temperature to the fall of pressure under conditions of constant total heat, when a gas flows steadily through a porous plug, it is possible to determine the variation of the total heat with pressure from the relation

$$Sd\theta/dp=\theta dv/d\theta-v. \qquad (16)$$

(*See* THERMODYNAMICS.) This method has the advantage of directly measuring the deviations from the ideal state, since $\theta dv/d\theta = v$ for an ideal gas, and the cooling effect vanishes. But the method is difficult to carry out, and has seldom been applied. Taken in conjunction with method (3), the observation of the cooling effect at different temperatures affords most valuable evidence with regard to the variation of the defect of volume $c-b$ from the ideal state. The formula assumed to represent the variations of c with temperature must be such as to satisfy both the observations on the compressibility and those on the cooling effect It is possible, for instance, to choose the constants in van der Waals's formula to satisfy either (3) or (4) separately within the limits of experimental error, but they cannot be chosen so as to satisfy both. The simplest assumption to make with regard to c is that it varies inversely as some power n of the absolute temperature, or that $c = c_0(\theta_0/\theta)^n$, where c_0 is the value of c at the temperature θ_0. In this case the expression $\theta dv/d\theta - v$ takes the simple form $(n+1)c-b$. The values of n, c and b could be calculated from observations of the cooling effect $Sd\theta/dp$ alone over a sufficient range of temperature, but, owing to the margin of experimental error and the paucity of observations available, it is better to make use of the observations on the compressibility in addition to those on the cooling effect. It is preferable to calculate the values of c and b directly from equation (16), in place of attempting to integrate the equation according to Kelvin's method because it is then easy to take account of the variation of the specific heat S, which is sometimes important

Having found the most probable values of the quantities c, b and n from the experimental data, the calculation of the correction may be effected as follows The temperature by gas thermometer is defined by the relation $T = pv/R$, where the constant R is determined from the observations at 0° and 100° C The characteristic equation in terms of absolute temperature θ may be put in the form $\theta = pv/R' + q$, where q is a small quantity of the same dimensions as temperature, given by the relation

$$q = (c-b)p/R. \qquad (17)$$

The constant R′ is determined, as before, by reference to the fundamental interval, which gives the relation $R'/R = 1 + (q_1 - q_0)/100$, where q_1, q_0 are the values of q at 100° and 0° C respectively.

The correction to be added to the fundamental zero T_0 of the gas thermometer in order to deduce the value of the absolute zero θ_0 (the absolute temperature corresponding to 0° C) is given by the equation,

$$\theta_0 - T_0 = q_0 - (q_1 - q_0)\theta_0/100 \qquad (18)$$

The correction dt to be added to the centigrade temperature t by gas thermometer reckoned from 0° C in order to deduce the corresponding value of the absolute temperature also reckoned from 0° C is given by the relation, deduced from formula (10),

$$dt = (q - q_0) - (q_1 - q_0)t/100, \qquad (19)$$

where q is the value at t° C of the deviation $(c-b)p/R$ The formulae may be further simplified if the index n is a simple integer such as 1 or 2. The values of the corrections for any given gas at different initial pressures are directly proportional to the pressure.

Values of the Corrections.—If we take for the gas hydrogen the values $c = 1{\cdot}5$ c.c. at 0° C, $b = 8{\cdot}0$ c.c., with the index $n = 1{\cdot}5$, which satisfy the observations of Joule and Thomson on the cooling effect, and those of Regnault, Amagat and Chappuis on the compressibility, the values of the absolute zero θ_0, calculated from Chappuis's values of the pressure and expansion coefficients at 100 cms. initial pressure, are found to be 273·10° and 273·05° respectively, the reciprocals of the coefficients themselves being 273·03 and 273·22. The corrections are small and of opposite signs. For nitrogen, taking $c_0 = 1{\cdot}58$, $b = 1{\cdot}14$, $n = 1{\cdot}5$, we find similarly 273·10° and 273·13° for the absolute zero, the correction $\theta_0 - T_0$ in this case amounting to nearly 1°. The agreement is very good considering the difficulty of determining the small deviations c and b, and the possible errors of the expansion and pressure-coefficients. It appears certain that the value of the absolute zero is within a few hundredths of a degree of 273·10°. Other observations confirm this result within the limits of experimental error. The value of the index n has generally been taken as equal to 2 for diatomic gases, but this does not satisfy either the observations on the cooling effect or those on the compressibility so well as $n = 1{\cdot}5$, although it makes comparatively little difference to the value of the absolute zero The value deduced from Travers's observation of the pressure-coefficient of helium is 273·13°, taking $n = \frac{1}{2}$, which is the probable value of the index for a monatomic gas The application of the method to the condensible gas carbonic acid is interesting as a test of the method (although the gas itself is not suited for thermometry), because its deviations from the ideal state are so large and have been so carefully studied. The observations of Joule and Thomson on the cooling effect give $c_0 = 3{\cdot}76$ c.c., $b = 0{\cdot}58$ c c., $n = 2$, provided that allowance is made for the variation of the specific heat with temperature as determined by Regnault and Wiedemann. Chappuis's values of the pressure and expansion coefficients agree in giving 273·05° for the absolute zero, the values of the corrections $\theta_0 - T_0$ being 4·6° and 5·8° respectively.

The values of the scale correction dt deduced from these formulae agree with those experimentally determined by Chappuis in the case of carbonic acid within the limits of agreement of the observations themselves. The calculated values for nitrogen and hydrogen give rather smaller differences than those found experimentally, but the differences themselves are of the same order as the experimental errors. The deviations of hydrogen and helium from the absolute scale between 0° and 100° C are of the order of ·001° only, and beyond the limits of accuracy of experiment. Even at −250° C (near the boiling-point of hydrogen) the corrections of the constant volume hydrogen and helium thermometers are only a tenth of a degree, but as they are of opposite signs, the difference amounts to one-fifth of a degree at this point, which agrees approximately with that observed by Travers. For a fuller discussion of the subject, together with tables of corrections, the reader may refer to papers by Callendar, *Phil. Mag.* v. p. 48 (1903), and D. Berthelot, *Trav. et Mém. Bur. Int. Paris*, xiii. (1903). Berthelot assumes a similar type of equation to that given above, but takes $n = 2$ in all cases, following the so-called law of corresponding states. This assumption is of doubtful validity, and might give rise to relatively large errors in the case of monatomic gases.

Limitations.—In the application of the gas thermometer to the measurement of high temperatures certain difficulties are encountered which materially limit the range of measurement and the degree of accuracy attainable. These may be roughly classified under the heads—(1) changes in the volume of the bulb; (2) leakage, occlusion and porosity; (3) chemical change and dissociation. The difficulties arise partly from defects in the materials available for the bulb, and partly from the small mass of gas enclosed. The troubles due to irregular changes of volume of glass bulbs, which affect the mercury thermometer at ordinary temperatures, become so exaggerated at higher points of the scale as to be a serious source of trouble in gas thermometry in spite of the twentyfold larger expansion.

The difficulties of leakage and porosity occur chiefly with porcelain bulbs, especially if they are not perfectly glazed. A similar difficulty occurs with metallic bulbs of platinum or platinum-iridium, in the case of hydrogen, which passes freely through the metal by occlusion at high temperatures. The difficulty can be avoided by substituting either nitrogen or preferably argon or helium as the thermometric material at high temperatures With many kinds of glass and porcelain the chemical action of hydrogen begins to be appreciable at temperatures as low as 200° or 300° C. In any case, if metallic bulbs are used, it is absolutely necessary to protect them from furnace gases which may contain hydrogen. This can be effected either by enclosing the bulb in a tube of porcelain, or by using some method of electric heating which cannot give rise to the presence of hydrogen. At very high temperatures it is probable that the dissociation of diatomic gases

like nitrogen might begin to be appreciable before the limit of resistance of the bulb itself was reached It would probably be better, for this reason, to use the monatomic and extremely inert gases argon or helium

On account of these and similar difficulties, it appears probable that the extreme limit of gas thermometry, even with the best metallic bulbs, must be placed in the neighbourhood of 1,600° C A great deal of valuable work has been done in recent years in this direction, especially at the Reichsanstalt and the U S A. Bureau of Standards, by which the limitations of our knowledge of the absolute scale in this region have been materially narrowed The methods employed in these researches do not involve any fresh questions of principle, and it would be impossible in the limits of the present article to give an intelligible account of the intricate details and results But it may be doubted whether any advantage gained by the extension of the bulb method, as usually practised, from 1,100° to 1,600° is not more than neutralised in point of accuracy by the subsidiary corrections, such as that for the expansion of the bulb, most of which increase in uncertainty more rapidly than as the square of t. At these and higher temperatures it would appear that the accurate extension of the absolute scale must rest primarily on improvements in the measurement of total radiation for which the fourth power law is now firmly established by comparison with the gas thermometer at lower temperatures over a very wide range (*See* HEAT)

Other Methods.—Many attempts have been made to overcome the difficulties of gas pyrometry by adopting other methods of measurement Among the most interesting may be mentioned: (i) The variation in the wave-length of sound The objection to this method is the difficulty of accurately observing the wave-length, and of correcting for the expansion of the material of the tubes in which it is measured There is the further objection that the velocity varies as the square root of the absolute temperature. (ii) A similar method, but more promising, is the variation of the refractivity of a gas, which can be measured with great accuracy by an interference method Here again there is difficulty in determining the exact length of the heated column of gas, and in maintaining the temperature uniform throughout a long column at high temperatures. These difficulties have been ingeniously met by D Berthelot (*Comptes Rendus*, 1895, 120, p. 831) But the method is not easy to apply, and the degree of accuracy attainable is probably inferior to the bulb method (iii) Methods depending on the effusion and transpiration of gases through fine orifices and tubes have been put in practice by Barus and by the writer The method of transpiration, when the resistance of the tube through which the current of gas is passed is measured on the Wheatstone bridge principle (*Nature*, 23rd March 1899), is extremely delicate, and the apparatus may be made very small and sensitive, but the method cannot be used for extrapolation at high temperatures until the law of increase of resistance has been determined with certainty. This may be successfully accomplished in the near future, but the law is apparently not so simple as is usually supposed

ELECTRICAL THERMOMETRY

The convenience of the mercurial thermometer lies in the fact that it is complete in itself, and can be read without subsidiary appliances beyond a magnifying glass. Its weakness lies in the very limited range of each single instrument, and in the troublesome and often uncertain corrections which must be applied to its readings in all work of precision. Electrical thermometers have the disadvantage of requiring auxiliary apparatus, such as galvanometers and resistances, the use of which involves some electrical training. But they far surpass the mercurial thermometer in point of range, delicacy and adaptability, and can be applied to many investigations in which ordinary thermometers are quite useless

There are two kinds of electrical thermometers, which depend on different effects of heat on the electrical properties of metals: (1) The *Thermocouple*, or *Thermopile*, which depends on the production of a thermoelectric force when the junctions of different metals in an electric circuit are at different temperatures; and (2) the *Electrical Resistance Thermometer*, the action of which depends on the fact that the resistance of a pure metal to the passage of an electric current increases very considerably when the temperature is raised. The theory of the thermocouple is discussed in the article THERMOELECTRICITY, as it possesses many points of interest, and has been studied by many skilful experimentalists. The electrical resistance thermometer is of more recent origin; but although the theory has been less fully developed, the practice of the method bids fair to surpass all others in the variety and accuracy of its applications. In order to secure the widest possible range and the greatest constancy, in either variety of electrical thermometer, advantage is taken of the great stability and infusibility characteristic of the metals of the platinum group. Other metals are occasionally used in work at low temperatures with thermocouples for the sake of obtaining a larger electromotive force, but the substitution is attended with loss of constancy and uncertainty of reduction, unless the range is greatly restricted

Applications of the Thermocouple.—The principal uses of the thermocouple in thermometry are for measuring high temperatures, and for measuring small differences of temperature, more particularly when the temperature is required to be measured *at a point*, or in a very small space. The electromotive force of the couple depends only on the temperature at the plane of junction of the two metals, which can be very exactly located A typical instance of a measurement to which the thermocouple is peculiarly suited is the determination of the cyclical variations of temperature at accurately measured depths from one-tenth to one-hundredth of an inch in the metal of the cylinder of a heat engine, the interior surface of which is exposed to cyclical variations of temperature in the working of the engine The exact depth of the plane of junction can be measured without difficulty to the thousandth of an inch The insertion of the wire makes the least possible disturbance of the continuity of the metal There is no lag, as the thermometer itself is part of the metal The instantaneous value of the temperature at any particular point of the stroke can be measured separately by setting a periodic contact to close the circuit of the galvanometer at the desired point A further advantage is gained by measuring only the difference of temperature between two junctions of a thermocouple at different depths, instead of the whole interval from some fixed point. None of these advantages could be secured by the use of any ordinary thermometer; some depend on the fact that the method is electrical, but some are peculiar to the thermocouple, and could not be otherwise attained

On the other hand, the thermocouple is not well suited for thermometry of precision on account of the smallness of the electromotive force, which is of the order of ten microvolts only per degree for the most constant couples By the use of very delicate galvanometers it is possible to read the hundredth or even in special cases to the thousandth of a degree on this small difference, but unfortunately it is not possible to eliminate accidental thermal effects in other parts of the circuit due to small differences of temperature and material These accidental effects seldom amount to less than one or two microvolts even in the best work, and limit the accuracy attainable in temperature measurement to about the tenth of a degree with a single platinum thermocouple. This limit can be surpassed by using couples of greater thermoelectric power and less permanence, or by using a pile or series of couples, but in either case it is doubtful whether the advantage gained in power is not balanced by loss of simplicity and constancy A method of avoiding these effects, which the writer has found to be of great use in delicate thermoelectric researches, is to make the whole circuit, including all the terminals and even the slide-wire itself, of pure copper. Platinoid, german silver, constantan and other alloys most commonly used for resistance and slide-wires, are particularly to be avoided, on account of their great thermoelectric power when connected to copper. Manganin and platinum-silver are the least objectionable, but the improvement effected by substituting copper is very marked. It is clear that this objection to the use of the couple does not apply so strongly to high temperatures, because the

electromotive force of the couple itself is greater, and the accuracy attainable is limited by other considerations.

The Resistance Thermometer.—In practice the resistance thermometer is almost invariably made of platinum, since there is very seldom any advantage to be gained by the substitution of baser metals. The instrument is for this reason often referred to simply as the "platinum thermometer." It is important that the platinum should be pure, both for the sake of uniformity and also because the change of electrical resistance with temperature is greatly diminished by impurities. The observation of the fundamental coefficient, which is ·00390 (or rather larger than the coefficient of expansion of a gas) for the purest metal hitherto obtained, is one of the most delicate tests of the purity of the metal. In addition to the constancy and infusibility of the metal, a special advantage which is secured by the use of platinum is the close agreement of the thermo-dynamical scale with the platinum scale of temperature, as defined by the formula

$$pt = 100(R - R_o)/(R_1 - R_o), \qquad (20)$$

in which the symbol pt stands for the temperature on the platinum scale centigrade, and R, R_1 and R_o are the observed resistances of the thermometer at the temperatures pt, 100° and 0° C respectively. A platinum thermometer is generally arranged to read directly in degrees of temperature on the platinum scale, just as a mercury thermometer is graduated in degrees on the mercury scale. The reduction to the scale of the gas thermometer is most conveniently effected by the difference formula

$$t - pt = dt(t - 100)/10{,}000, \qquad (21)$$

in which d is a constant, called the difference-coefficient, the value of which for pure platinum is 1·50, but varies somewhat for commercial specimens. This formula was first given by H. L. Callendar as the result of a series of comparisons of different platinum wires with each other and with other metals, and also with an air thermometer over the range 0° to 625° C. The platinum wire in these comparisons was enclosed inside the bulb of the air thermometer itself, and disposed in such a manner as to be at the mean temperature of the bulb in case the temperature was not quite uniform throughout (*Phil. Trans.* A. 1887, p. 161). The formula was subsequently verified by C. T. Heycock and F. H. Neville (*Journ. Chem. Soc.* February 1895), by the observation of a number of higher points up to the freezing-point of copper at 1,082° C, which they showed to agree with the most probable means of all the best determinations by various methods of gas thermometry.

FIG. 6.—MEYER TUBE APPARATUS

The difference-coefficient d in formula (21) could evidently be determined by reference to any fixed point on the absolute scale which was known with sufficient accuracy by observations with a gas-thermometer. The boiling-point of sulphur happens to be most convenient for this purpose, as first proposed by Callendar and Griffiths (Phil. Trans. A. 1891, p. 119) and adopted by all subsequent observers. The annexed figure 6 shows the form of apparatus they proposed for the standardization of platinum thermometers on this basis. Similar forms are still employed with slight variations in points of detail. Sulphur is boiled in the bulb B at the base of a hard glass tube about 4cm. in diameter, such as is used for vapour-density determinations by the method of Victor Meyer, and is often called a "Meyer" tube. An asbestos board CD prevents the flame reaching the sides of the tube above the level of the liquid, and minimises the risk of superheating of the vapour. The upper part of the tube is lagged with about 2 cm. of asbestos wool to reduce external loss of heat, except for 3 or 4 cm. at the top which is left bare to serve as a condenser. The top is covered with a sheet of asbestos through which the thermometer M is inserted. The gas is adjusted to keep the sulphur vapour at a steady level A near the top of the tube. A cone of asbestos board surrounds the lower half of the lagging to give it greater stability and further diminish the rate of cooling. The condensed liquid trickles down the sides of the tube, and also to some extent down the stem of the thermometer. It was found that a naked thermometer inserted in the tube under these conditions might indicate a temperature nearly 2° lower than that of the condensing vapour owing to loss of heat by radiation to the sides in addition to the cooling effect of the liquid. These losses could be practically eliminated by fixing an umbrella E on the upper part of the thermometer tube to divert the liquid stream, and two concentric screens round the bulb to protect it from loss by radiation to the sides. The bulb was also protected from the boiling liquid below by two perforated screens H, but this seemed to make little difference, as the liquid was little if at all superheated, and boiled very quietly. This apparatus gave very consistent results, to nearly 0·01° C, with three different thermometers constructed from the wire spiral which had been directly compared with the gas-scale in the bulb of the air thermometer employed in 1887, and which gave the value d = 1·57. This value was again verified by comparing one of these thermometers with the same air thermometer in a bath of sulphur vapour. Employing this value, the temperature of the boiling point of sulphur at a pressure of 760 mm was found to be 444·53° C on the scale of the constant-pressure air thermometer. Chappuis and Harker (1902) found the value 445·2° C on the scale of the *constant-volume* nitrogen thermometer, but this was subsequently corrected to 444·7° C to allow for a probable error in the expansion of the bulb. Eumorfopoulos (1908) found the value 444·55° using a constant-pressure air thermometer of the type shown in figure 5, with a glass bulb, but later in 1914 using the same thermometer with a bulb of fused quartz, having a much smaller coefficient of expansion, he found 444·13 on the same scale, and 444·61 on the thermodynamic scale.

Construction of Platinum Thermometers.—Figure 7 gives an enlarged view of the platinum spiral of the thermometer shown in the sulphur apparatus in figure 6. This was one of the first thermometers constructed by the writer with platinum leads and mica insulation for use at high temperatures. The fine wire of the coil was fused on to the platinum leads without employing any gold or silver solder, which might contaminate the wire, and would limit the temperature to which it could be exposed. This particular thermometer was constructed primarily for testing how closely the scales of two pieces of wire from the same reel would agree with each other. With this object the two spirals were wound in a double helix, being threaded through fine holes in a thin plate of mica AB to keep them in place, without contact at any point, but so close together that their mean temperatures would be the same even if the distribution of temperature in the tube were not quite uniform. One of the wires is shown by a dotted line in the figure to distinguish the two. Each coil has three leads, one of the leads being double in each case, for the purpose of securing automatic compensation of the resistance of the leads, and freedom from stem-exposure correction. The platinum leads were insulated and held in place by being threaded through mica discs, one of which is shown at C. This method is still generally adopted, and has the advantage of giving very perfect insulation at high temperatures, besides preventing convection currents up and down the tube. No difference exceeding 0·01° C could be detected between the scales of the two spirals, by differential measurements up to 600° C. Owing to the double winding, the insulation of the coils could be verified with great accuracy at any moment during the observations. This pattern was intended for use with a duplex compensated bridge, made for Lea and Gaskell (*Jour. Phys.*, 1887), giving double the sensitivity of a single bridge, and capable of calibration without the use of external resistances. It was found however that the single bridge could be so easily calibrated against another similar bridge, and that the thermometer with a single coil had such a large excess of sensitivity, that the duplex combination was abandoned as being unnecessarily complicated and expensive.

A thermometer with a single coil, wound on a serrated plate or cross of mica, is much easier to make than the duplex pattern, and has the advantage of superior immunity from damage if the tube is broken. It differs from the duplex pattern illustrated in the figure by having four leads instead of six, the pair for the compensator being separate from the pair connected to the coil, but otherwise exactly similar, and similarly insulated with mica discs The insulation of the *coil* cannot be tested in this pattern except by inspection after removing the tube, but is not likely to give trouble unless the tube is cracked or damp The insulation of the leads is easily tested, and usually gives sufficient warning of any trouble of this kind. The potentiometer method, which is sometimes used for measuring the resistance, requires that a pair of leads should be connected *to each end* of the coil This method eliminates the resistance of the leads, if the balance is perfect, but does not permit a satisfactory insulation test, and depends too much on the constancy of the current, besides being inapplicable to differential measurements, or to the exact elimination of accidental thermoelectric effects On the other hand in the Wheatstone bridge method, the equality of the compensator and pyrometer leads must be carefully tested in the construction of the thermometer, but is not likely to give trouble if the resistance of the coil is large compared with that of the leads, as is usually the case in thermometers employed for work of precision at moderate temperatures, such as 500° C. The leads are often connected to terminals at the head of thermometers, as indicated at M in figure 6. For work of the highest precision these terminals are better omitted, and the leads directly soldered to a flexible cable in order to avoid possible errors from thermoelectric effects and changes of resistance of the screw terminals For temperatures above 600° C the protecting tube should be of porcelain, and the leads of platinum throughout that part of the tube which is exposed to high temperatures For lower temperatures a tube of hard glass and leads of gold or silver may be employed, but it is better in any case to make the lower part of the leads of platinum in order to diminish the conduction of heat along the stem. For laboratory work a tube 30 or 40 cm in length usually suffices, but for large furnaces the length of the protecting tube is often 5 to 10 ft. In the latter case it is usual to protect the porcelain tubes with an external steel tube, which may be removed for delicate measurements.

FIG 7—SPIRAL OF THERMOMETER M

Special Forms of Thermometer.—In the measurement of linear expansion it is a great advantage to employ a thermometer with the bulb or sensitive portion equal in length to the bar or column under test, so as to obtain the mean temperature of the whole length. In measuring the linear expansion of a standard metre or yard, a fine platinum wire enclosed in a glass capillary, or otherwise insulated, is employed, its length being equal to that of the bar. The same method has been applied by Callendar (*Phil. Trans.* A, 1887) and Bedford (*Phil. Mag*, 1898) to the expansion of glass and porcelain at high temperatures, employing a fine wire supported along the axis of the tube under test An equivalent method, applied to the expansion of silica by Callendar, is to enclose a rod of the material inside a platinum tube which is heated by an electric current. This is a very rapid and convenient process, since the mean temperature of the rod must be equal to that of the enclosing tube. Any temperature up to the melting-point of platinum is readily obtained, and easily regulated The temperature may be obtained by observing either the resistance of the platinum tube or its linear expansion Either method may also be employed in J. Joly's meldometer, which consists of an electrically heated strip for observing the melting-points of minerals or other substances in small fragments. In observing the temperature of a long column of mercury, as in the method of equilibrating columns for determining the absolute expansion of mercury, a platinum thermometer with a bulb equal in length to the column may similarly be employed with advantage (Callendar & Moss, *Phil. Trans.* A, 1911, p 1). The application is here particularly important because it is practically impossible to ensure perfect uniformity of temperature in a vertical column, 6 ft. or more in length, at high temperatures.

Sensitive Thermometers.—Where quickness of reading is essential, the mercury thermometer, or the tube form of electric thermometer, is unsuitable In cases where the thermometer has to be immersed in a conducting liquid or solution, the fine wire forming the bulb may be insulated by enclosing it in a coiled glass capillary. This method has been employed by Callendar and Barnes and by Jaeger, but the instrument is necessarily fragile, and requires careful handling. For non-conducting liquids or gases the bare wire may be employed with great advantage. This is particularly important in the case of gases owing to the extreme sensitiveness thus obtained and the almost complete immunity from radiation error at moderate temperatures. Thermometers constructed in the form of a flat grid of bare wire mounted on a mica and ebonite frame have been employed by H Brown (*Proc R S*, 1905, B 76, p 124) for observing the temperature of leaves and of air currents to which they were exposed They have also been employed for observing the air-temperature for meteorological purposes in Egypt and Spain with very satisfactory results (*Proc R.S*, 1905, A 77, p 7). The fine wire, owing to its small size and bright metallic surface, very rapidly acquires the temperature of the air, and is very little affected by radiation from surrounding objects, which is one of the chief difficulties in the employment of mercurial thermometers for the observation of the temperature of the air.

For the observation of rapidly varying temperatures, such as those occurring in the cylinder of a gas- or steam-engine, an electrical thermometer with very fine wire, of the order of ·001 in. diameter is practically the only instrument available. The temperature at any particular moment may be obtained by setting a mechanical contact-maker to close the circuit at the desired point The sensitive part of the thermometer consists simply of a loop of fine wire from half an inch to an inch long, connected by suitable leads to the measuring apparatus as employed by Burstall (*Phil Mag*, October 1895) in the gas-engine, and Callendar and Nicolson (*Proc. Inst.* C E, 1898) in the steam-engine The explosion temperatures cannot be satisfactorily measured in a gas-engine in this manner, because the radiation error at high temperatures is excessive unless the wire is very fine, in which case it is very soon melted even with weak mixtures. Callendar and Dalby accordingly devised a mechanical valve (*Proc R S*, A 80, p 57) for exposing the thermometer only during the admission and compression strokes, and have deduced the actual explosion temperatures from the indicator diagram B. Hopkinson (*Proc. R S.*, A 77, p. 387) succeeded in following the course of an explosion in a closed vessel by means of a similar thermometer connected to a galvanometer of short period giving a continuous record on a moving photographic film. When the flame reached the wire the temperature rose 1,200° C in about ·01, of a second, which illustrates the order of sensitiveness attainable with a fine wire of this size. O. R Lummer and E Pringsheim, in their measurements of the ratio of the specific heats of gases by observing the fall of temperature due to sudden expansion, employed a very thin strip of foil with the object of securing greater sensitiveness. This was a somewhat doubtful expedient, because such a strip is extremely fragile and liable to be injured by air currents, and because the sensitiveness is not as a matter of fact appreciably improved, whereas the radiation error is increased in direct proportion to the surface exposed One of the principal sources of error in employing a short loop of fine wire for observing rapidly varying temperatures is that the ends of the loop close to the thick leads are affected by conduction of heat to or from the leads, and cannot follow the rapid variations of temperature. This error may be readily avoided by the method, first employed by Callendar and Nicolson, of

connecting the compensating leads with a short length of the same fine wire. (*See* THERMODYNAMICS.)

Errors and Corrections.—It is most instructive to consider the errors and corrections involved in platinum thermometry on the same lines as those on which the corresponding errors of the mercury thermometer have already been treated

I. The changes of zero of the mercury thermometer arise chiefly from the small expansibility of mercury combined with the imperfect elasticity of the containing tube In platinum thermometry, the containing tube has nothing to do with the reading, and the effect of any possible strain of the fine wire of the coil is minimized by its small dimensions and by the large temperature-coefficient of the increase of resistance, which is more than twenty times greater than the coefficient of apparent expansion of mercury in glass. It is not surprising, therefore, that the changes of zero of a platinum thermometer should be practically negligible, provided that the wire is not strained or contaminated with impurities. It is probable that with ordinary care the changes of zero due to exposure to any given limits of temperature are in all cases less than the limit of accuracy of observation, due to other causes at the extreme limit of the range considered

II *The fundamental interval* of each thermometer must be determined as usual by observations in ice and steam, and a correction must be applied by the method already described in the case of the mercury thermometer The difference of the temperature of the steam from 100° C should be determined on the platinum scale by the formula

$$dpt_1 = 985dt_1 = \cdot 0362(H-760) - \cdot 000020(H-760)^2 \quad (22)$$

III *Pressure Correction*—The effect of change of pressure on a platinum thermometer of the ordinary tube form is of course nothing, as the wire itself is not exposed to the pressure. Even if the wire is naked and directly exposed to large changes of pressure, the change of reading is almost inappreciable Similarly there is no source of error analogous to the effects of capillarity, which are so troublesome with delicate mercury thermometers

IV *Stem Exposure*—The reading of a platinum thermometer with compensated leads depends only on the temperature of the coil of wire forming the bulb, and not on the temperature of the stem, provided that the immersion is sufficient to avoid errors due to conduction or convection along the stem It is desirable that the top of the bulb should be immersed to a depth equal to from three to ten times the diameter of the tube, according to the accuracy required

V. *Scale Correction.*—The reduction to the thermodynamical scale may be effected, within the limits of probable error of the most accurate measurements at present available, by the very simple difference formula (21) already given, over the whole range from −100° C to + 1,100° C This is in striking contrast with the mercury thermometer, which requires a cubic formula to cover the range 0° to 200° C with equal accuracy The value of the constant d in the formula varies but little, provided that the wire be fairly pure and the thermometers properly constructed

VI. *Calibration Correction*—The calibration of the resistance box and the bridge-wire corresponds to the calibration of the stem of the mercury thermometer, but the process is much simpler for several reasons It is more easy to obtain a uniform wire than a uniform tube The scale of the wire is much more open, it corresponds to a very small part of the whole scale, and the process of calibration is easier One box when calibrated will serve for any number of thermometers of different ranges and scales, and covers the whole range of temperature (*See* CALIBRATION)

Electrical Precautions.—The platinum thermometer is so far superior to the mercury thermometer in all the points above enumerated that, if there were no other difficulties, no one would ever use a mercury thermometer for work of precision. In using a platinum thermometer, however, some electrical training is essential to obtain the best results The manipulation and adjustment of a delicate galvanometer present formidable difficulties to the non-electrical observer. Bad contacts, faulty connections, and defective insulation, are not likely to trouble the practised electrician, but present endless possibilities of error to the tyro. Trouble from bad contacts generally arises from the use of plugs for the resistance coils. If plugs are used, they must be specially designed so as not to disturb each other, and must be well fitted and kept very clean. Mercury cups with large copper terminals, well amalgamated, as used with standard resistance coils, are probably the simplest and most satisfactory method of changing connections Accidental thermoelectric effects in the circuit are a possible source of error, as with the thermocouple, but they are

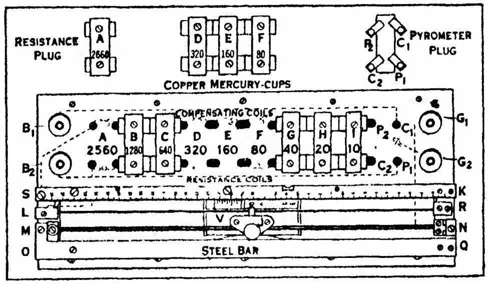

FIG 8—COMPENSATED RESISTANCE BOX FOR USE WITH PLATINUM THERMOMETERS

always very small if the thermometer is properly constructed, and are relatively unimportant owing to the large E M F available. In any case they may be completely eliminated by reversing the battery. The heating effect of the current through the thermometer is often negligible, but should be measured and allowed for in accurate work

Methods and Apparatus.—The methods of electrical thermometry may be roughly classified under two heads as (1) deflection methods, in which the temperature is deduced from the observed deflection of a galvanometer; and (2) balance methods, in which the resistance or the electromotive force is balanced against a known adjustable resistance or potential difference The former methods are most suitable for rough work and rapid reading, the latter for accurate measurements In the practice of the deflection method it is customary to use a moving-coil galvanometer, the sensitiveness of which can be varied by varying the resistance in circuit, or by varying the stiffness of the suspension The accuracy attainable is of the order of one-half of 1 per cent on the deflection, and is limited by variations of resistance of the galvanometer, and by the imperfect elasticity of the suspension In any case the scale of the galvanometer should be calibrated or tested for uniformity In this kind of work the thermocouple has the advantage over the resistance thermometer in that the latter requires an auxiliary battery to supply the current; but in many cases this is no disadvantage, because it permits a greater latitude of adjustment, and makes it possible to obtain greater power than with the thermocouple

In cases where it is desired to obtain greater accuracy without abandoning the quickness of reading which is the principal advantage of the deflection method, it is possible to combine the two methods by balancing part of the potential difference by means of a potentiometer and using the galvanometer for the small changes only In cases where the greatest accuracy is required, a very sensitive galvanometer should be used, and the whole of the potential difference should be balanced as nearly as possible, leaving very little to depend on the deflection of the galvanometer The degree of sensitiveness and accuracy obtainable depends primarily on the delicacy of the galvanometer, on the power available, and on the steadiness of the conditions of experiment. For thermometry of precision the resistance thermometer possesses three very great advantages over the thermocouple: (1) The power available, owing to the use of a battery, is much greater; (2) it is possible completely to eliminate the errors due to accidental thermal effects by reversing the battery; (3) the Wheatstone bridge method can be employed in place of the potentiometer, so that the constancy of the battery is immaterial, and it is not necessary to use a standard cell. Another disadvantage of the potentiometer method as applied to resistance thermome-

ters, is that it is unsuited for differential measurements, which are so commonly required in calorimetric work.

Compensated Bridge Method and Apparatus.—The type of Wheatstone bridge illustrated in figure 8, page 123, though one of the oldest, is still in use for work of precision, and illustrates most of the essential points to be aimed at in work of this kind. The box measures only 15″×6″×3″, and was designed primarily with a view to cheapness and portability at a time when apparatus for research was scarce and had often to be moved from one laboratory to another The figure shows a plan of the ebonite lid, on the top of which the connections are marked in dotted lines. B_1, B_2 are the battery terminals, which are connected through a reversing key and a rheostat of about 200 ohms to a 2-volt storage cell. G_1, G_2 are the galvanometer terminals, connected to a moving-coil galvanometer of about 10 ohms resistance, which is critically damped by a suitable shunt to save time in reading the deflections. The four leads of each pyrometer, several of which may be read in succession, are permanently connected to a 4-point plug consisting of an ebonite block with amalgamated copper rods, P_1, P_2 for the pyrometer leads from the platinum coil, and C_1, C_2 for the compensator leads, fitting the corresponding mercury cups in the bridge. It is a matter of a few seconds only to change pyrometers, and there is very little risk of error from bad contacts The least defect of insulation of the leads can be detected at any moment by shifting the pyrometer plug so that the points P_1, C_2 are inserted in the cups C_1, P_2 leaving P_2, C_1, disconnected This test is apt to be neglected unless it is made very easy. It puts nearly the whole voltage of the battery on to the galvanometer through the defective insulation The cups C_1, P_1, are directly connected to the battery terminals as indicated, and also to a pair of equal resistances of about 6 ohms each forming the ratio arms of the bridge, the middle point between the two being connected to the galvanometer terminal G_2. These ratio coils are separately wound with bare wire on mica plates to secure perfect insulation, and are very carefully annealed and tested for equality of temperature coefficient They are fixed symmetrically side by side so that both are always at nearly the same temperature The cup C_2 is connected to one end of a series of 9 resistance coils, A, B, C, D, etc , the other end of which is connected to the left side of the bridge-wire LR The cup P_2 is similarly connected to one end of a series of compensating coils, the other end of which is connected through the millimetre scale SK to the right side R of the bridge-wire LR The double wire MN stretched parallel to LR is connected to G_1, and to any point of LR through the sliding contact J, which carries a vernier V, reading to 0·01 mm. on the scale SK.

Temperature Compensation of Resistance Coils—In order to obtain accurate measurements of changes of resistance of the thermometers, it is necessary, either that the box coils should not change, or else that the readings should be corrected for any variation of temperature of the box. This can be done by observing the temperature of the box and applying a correction if the temperature coefficient of each individual coil is known with sufficient accuracy, and if they are all at the same temperature immersed in a well-stirred oil bath It is also possible to regulate the temperature of the oil bath with a thermostat. But these methods are very troublesome, and would be quite unsuitable for a portable apparatus A method of equal, if not superior, accuracy is to compensate each individual resistance coil with a compensating coil, as shown in the figure, connected on the opposite side of the bridge-wire, both coils being cut in or out of circuit simultaneously by a 4-point mercury plug. The effective resistance of the pair is the difference between them, which will remain constant if their values are so adjusted that the increment of each per 1° is the same. The resistance coils are made of platinum-silver alloy, which has a temperature coefficient about 14 times smaller than that of platinum. The wire is wound on mica and enclosed in a glass tube like a platinum thermometer. The compensator is a loop of platinum wire of the same length as the platinum-silver coil, but has a resistance 14 times smaller The two are tested together in the glass tube at temperatures between 10° and 30°, and are adjusted until their difference has the desired magnitude and shows no detectable change over this range of temperature The glass tube and leading wires are then cut to a suitable length, and the compensated pair is connected in its proper place in the box. The platinum compensating coils may be regarded as peculiarly delicate and appropriate thermometers for measuring the mean temperature of each individual coil, which would otherwise be difficult. But they go a step further, and apply the necessary correction automatically, without any waste of time or attention on the part of the observer.

The effective values of the compensated coils are adjusted to give a range of resistances from 0·1 to 25·6 ohms on the binary scale in order to facilitate calibration, since their relative values are required with the greatest possible accuracy (*See* CALIBRATION) The smallest coil, marked I, is equivalent to 10 cm. of the bridge wire, or to 1° C with a thermometer having a fundamental interval of 10 ohms, and a zero resistance of approximately 25·6 ohms, which is that of the largest coil in the box

Adjustment of Bridge-wire—In using the bridge by the balance method, the resistance is balanced with the coils A, B, C, D, etc , to the nearest 0·1 ohm The next three figures may be obtained by finding the balance point on the bridge wire to 0·1 mm The bridge-wire is made of platinum-silver and is drawn down to a resistance slightly exceeding 0·005 ohm per cm , giving an effective resistance (in terms of shift of the balance point) equal to double its actual resistance, or a little more than 0·01 ohm per cm , so that a length of *less* than 10 cm. is equivalent to the smallest coil I Its whole length from L to R is then shunted with a suitable resistance until a length of 10 cm near the middle of the wire is precisely equivalent to the coil I The whole length may then be tested for uniformity against coil I, but should not vary by more than 1 in 1,000 if the wire is of uniform quality and carefully drawn It is seldom necessary to calibrate the bridge-wire more accurately than this, since it is employed only for measuring small differences, averaging 0·0025 ohm, for which an accuracy of about 0·0000025 ohm usually suffices It is most important, however, to keep it stretched at a uniform and constant tension, and to ensure that it is not damaged by the sliding contact, and does not shift relatively to the scale SK This cannot be secured by fixing it with reference to the ebonite base at both ends, because the coefficient of expansion of ebonite is so much larger than that of the wire Accordingly the bridge-wire LR is mounted on a frame, with the brass scale SK on one side and a steel bar OQ on the other, in a position corresponding approximately with its coefficient of expansion, which is intermediate between that of brass and that of steel The right hand ends K,Q of these bars are fixed to the ebonite lid, but the left hand ends S,O, are free to slide so as to maintain the tension constant The galvanometer wire MN is also of platinum-silver and similarly mounted Contact is made between the two wires LR and MN at the sliding contact J by means of a short length of the same platinum-silver wire, with a sharp edge, rigidly fixed to the vernier carriage at right angles to the scale Normally the bridge-wire is held just clear of the contact piece by the flanges of the carriage, and the galvanometer circuit is open Contact is made at any desired point by turning an ebonite screw, which locks the carriage, and presses the bridge wire down on the contact piece by means of an ebonite finger, with a renewable sleeve of soft rubber tubing, so that neither the wire, nor the sharp edge of the contact, is damaged. The contact is held by the screw while the battery is reversed to test the balance and eliminate thermal effects. If the balance is not exact, the deflection of the galvanometer is noted, and the contact is released and moved in the required direction. After two readings of deflection, the balance point may be found by interpolation

Mercury Plug Mechanism—Some of the plugs are removed from the box in figure 6 to show the mercury cups and connections. In practice the plugs are not removed, but merely raised vertically and kept suspended about half an inch above their respective cups, so that any mercury that may drip from the amalgamated rods falls back into the cup from which it came. To the centre of each 4-point plug is attached a brass rod sliding vertically in an overhead bar running the length of the box, and supported on pillars at either end. The plug is held in the raised position and

prevented from turning by a ball and spring catch sliding in a groove in the brass rod. Four or five of the plugs can be raised or depressed simultaneously with one hand, so that the manipulation involved in changing the resistance is far quicker than with any other type of plug box. The mercury plugs and cups give more perfect contact and are much easier to clean than ordinary brass plugs and sockets The overhead bar, together with all the plugs, can be removed in a few seconds by unscrewing two thumb-nuts, on the rare occasions when the cups require refilling or cleaning These provisions are of special importance in industrial work, where the apparatus may be exposed to damp, or dust, or gas fumes, and the object is to save time In such an environment it is often advisable to enclose the whole box in a dust-proof case, leaving only the operating rods exposed, and to abandon the use of the bridge-wire and balance method under such conditions in favour of the deflection method next described.

Deflection Method (for Fractions of 1°).—The method of finding the balance point on the bridge-wire as above described is the most sensitive and accurate for measuring a *constant* resistance, as in testing the coils, or calibrating the box, or observing the fixed points of a thermometer in ice or steam But it requires at least two accurate settings of the contact, and recording two readings of the vernier and of the corresponding deflections of the galvanometer, in addition to the coils in circuit. In many cases the highest degree of accuracy is unnecessary, and the use of the balance method is inexpedient, especially at high temperatures, where an accuracy of 0·01° C is usually ample, and the resistance is seldom sufficiently constant to permit more exact readings In such cases the most convenient and rapid method of operation is to fix the bridge-wire contact at any convenient zero, set the coils to the nearest whole degree, and read the fraction of a degree by observing the deflection of the galvanometer on reversing the battery current This takes about a tenth of the time and trouble involved in a balance reading, and is the most appropriate method to employ in reading a number of different thermometers at regular intervals If the thermometers are at widely different temperatures, as often happens in practice, the balancing coils as well as the thermometers must be changed at each observation But since the coils required for any particular thermometer usually remain the same for an hour or so, these can be recorded before commencing observations as soon as the temperature is sufficiently steady The change from one thermometer to the next can be effected very quickly with the box and connections as illustrated in figure 8, and it is possible to read and record the deflections at the rate of 2 or 3 a minute. The coils required for each thermometer can be readily reduced to degrees of temperature from a knowledge of the fundamental intervals, which seldom differ by as much as 1 in 1,000. But the reduction of the observed deflections to the corresponding fractions of a degree, requires different factors for each thermometer in this method of operation, depending on the coils in circuit. The required factors are readily observed under any conditions by observing the change of deflection on reversal produced by putting the smallest coil I in or out of circuit But it saves a good deal of trouble in practice to keep the galvanometer deflection constant at 100 mm per 1° in all cases. This can be done automatically by adding a simple accessory, called a differential connector, which makes it possible to use the box for the direct observation of the difference between any two thermometers, and also permits the enclosure of the box itself in a dust-proof case

Differential Measurements.—Accurate measurements of difference of temperature between two thermometers are often required in calorimetric work, and are most readily secured by using a pair of platinum thermometers, connected on opposite sides of the bridge, so that the difference is obtained by a single reading, which is necessarily simultaneous for the two, and saves more than half the time required for reading each separately. The arrangement of connections for reading two thermometers differentially could easily be made on the bridge itself by omitting the resistance I and inserting a second pyrometer plug R_2 in its place, side by side with the plug R_1 belonging to the first pyrometer. The bridge reading would then give the difference R_2-R_1 and the difference R_1-R_2 could similarly be obtained by simply interchanging the plugs R_1 and R_2 The most accurate method of finding the difference is by observing the shift of the balance point on the bridge-wire, as in Carey Foster's method, when R_1 and R_2 are interchanged. But it is preferable in dealing with large differences to observe the coils and the galvanometer deflection, and to subtract a zero reading, taken when R_2 is at the same temperature as R_1 This zero should be verified daily as a matter of precaution for any pair of thermometers, but is not likely to vary appreciably unless the contacts require cleaning

Instead of making any such changes of connections on the box itself, it is more convenient in practice, for differential measurements and similar purposes, to employ an external set of mercury cups similar to those on the top of the box, but with fewer cups Such an arrangement may be called a differential connector The left side of the series of cups is connected through a pyrometer plug to the cups C_2, P_2 on the bridge, and the right side to the cups C_1, P_1 by the same plug The effect is the same as if the series of cups in the differential connector were interpolated between the points C_1P_1 and C_2P_2 on the bridge But this would be inconvenient on the bridge itself, because the mechanism required for the resistance plugs cannot perform the manipulation of interchanging pyrometer plugs Spaces for 4 pyrometer plugs are usually provided on the differential connector No 1, on the left, is usually occupied by a pyrometer in steam at atmospheric pressure, serving as a convenient standard of reference in many cases Any pyrometer R_2 inserted in No 2, can be read by difference from 100° C if spaces 3 and 4 are short-circuited with resistance plugs As a rule spaces 3 and 4 are occupied by auxiliary resistances in the form of compensated coils, made like those in the box, and enclosed in glass tubes, but provided with plug connectors like a pyrometer

Constant-current Method.—It is a great convenience in practice, especially for differential measurements over considerable ranges of temperature, to keep the sensitivity of the galvanometer automatically constant at a convenient figure, such as 100 mm per 1°, in spite of any variation of resistance of the pyrometers This requires that the measuring current should be kept constant, or that the whole resistance in circuit should remain the same, to about a half of 1 per cent, or less, if an accuracy of 0·01° is required with a scale deflection of 100 mm per 1°. This is effected by inserting in spaces Nos 3 and 4 on the differential connector one or two compensated coils having a total resistance larger than the difference to be measured, say 19·2 ohms, equivalent to the sum of coils B and C in the box, or to 384° C on the platinum scale, if the differential thermometers R_1 and R_2 have each a fundamental interval of 5 ohms With R_1, R_2 at the same temperature in a hypsometer, the bridge should then balance with B and C up in the box, and the bridge-wire contact fixed at zero Observe the deflection, if any, produced by reversing the battery. Raise coil I, which is equivalent to 2°. Observe the deflection again The difference of the two deflections should be 200 mm. If not, adjust the resistance of 200 ohms in the battery circuit until the desired sensitivity of 100 mm per 1° is secured This will remain constant for a week or so if the battery is good It will also be unaffected by any variation of R_2 (or by the substitution of other similar thermometers in the place of R_2) provided that the coils-up in the box are *reduced* as R_2 increases so as to keep the total resistance on the left side of the bridge wire balanced against the constant resistance $19·2+R_1$ on the right within 1° C. It is very easy to read to 0·01° C by this method on the galvanometer deflection, but the galvanometer deflection is less than a quarter of 1 per cent of the difference measured at 500° C, and it will be understood that it is essential that the resistance coils and thermometers must be most perfectly *compensated*, and that the deflection must be observed by *reversing* the battery in order to eliminate accidental thermoelectric effects, if an accuracy of 0·01° C is expected in the final result Neglect of the last precaution alone may easily cause an error of 1° if the thermometer is badly made.

Optical or Radiation Pyrometers.—Since the intensity of radiation increases very rapidly with the temperature of the

source of radiation, instruments for measuring radiation may be applied for measuring temperature, assuming that the laws connecting radiation and temperature are known. The advantage of this method is that the measurement may be made from a distance without exposing any part of the measuring apparatus to the destructive action of high temperatures. Apart from the difficulty of calibrating the measuring apparatus to give temperature in terms of radiation, the chief source of uncertainty in the application of the method is the emissive power of the source of radiation The methods principally employed may be divided into two classes.—(1) Radiation methods, depending on the measurement of the radiant energy by means of a radiometer, thermocouple or bolometer; (2) optical or photometric methods, depending on the colour or luminous intensity of the radiation as compared with a suitable standard.

Of the radiation methods the simplest in theory and practice depends on observing the total intensity of radiation, which varies as the fourth power of the absolute temperature according to the Stefan-Boltzmann law (*see* HEAT) for a perfectly black body or full radiator. In applying this method it is very necessary to allow for the emissive power of the source, in case this does not radiate as a black body Thus the emissive power of polished platinum at 1,000° Abs. is only 10 per cent, and that of black iron oxide about 40 per cent. of that of a black body; and the percentage varies differently for different bodies with change of temperature, and also for the same body according to the part of the spectrum used for the measurement. Owing to the rapid increase of radiation with temperature the error due to departure from black body radiation is not so serious as might be imagined at first sight. If the temperature of a polished platinum strip at 1,500° C were estimated by the radiation formula, assuming the constant for a perfectly black body, the error for red light would be about 125°, for green about 100°, and for blue about 75°. Such errors may be corrected when the emissive power of the source at various temperatures is known from previous experiments, but it is preferable to observe, whenever possible, the radiation from the interior of a uniformly heated enclosure which approximates very closely to that of a black body. (*See* HEAT)

Radiation pyrometers of this type are generally calibrated by the method of sighting on the interior of an electric furnace containing a thermocouple or gas-thermometer by which the temperature is measured The gas-thermometer has been employed for verifying the law of radiation up to 1,500° C, but the difficulties of obtaining accurate results with the gas-thermometer increase so rapidly above 1,200° C that it is questionable whether any advantage is gained by using it beyond this point. The law of radiation has been so closely verified by observations at lower temperatures that the uncertainty involved in applying it at higher temperatures, in the case of a black body is probably less than the uncertainty of the gas-thermometer measurements, and much less than the uncertainty of extrapolating an empirical formula for a thermocouple. Thus L. F. C. Holborn and W. Wien (*Wied. Ann.*, 1895, 16), by extrapolating their thermoelectric formula, found the value 1,587° C for the melting-point of palladium, whereas Violle found 1,500° C by the calorimetric method, and Callendar and Eumorfopoulos (*Phil. Mag.*, 1899, 48) found 1,540° and 1,550° C by the methods of the expansion and the change of resistance of platinum respectively. By a later thermoelectric extrapolation Holborn and Henning (*Berlin Akad.*, 1905, 12, p. 311) found 1,535° C for the melting-point of palladium, and 1,710° C for that of platinum, values which were strikingly confirmed by J. A. Harker at the National Physical Laboratory, and by Waidner and Burgess at the Bureau of Standards, U S.A. Holborn and Valentiner employing an optical method (*Ann. Phys.*, 1907, 22, p. 1) found 1,582° C and 1,789° C for palladium and platinum respectively. There can be little doubt that the extrapolation of the parabolic formula for the thermocouple at these temperatures is quite untrustworthy and that the values given by the electrical resistance method, or by the laws of radiation, are more likely to be correct. Assuming that the total radiation varies as the fourth power of the absolute temperature, a radiation pyrometer can be calibrated by a single observation at a known temperature, such as the melting-point of gold, 1,063° C if a black body is employed as the source; and its indications will probably be accurate at higher temperatures under a similar restriction. If the pyrometer is sighted on the interior of a furnace through a small observation hole it will indicate the temperature of the furnace correctly, provided that the temperature is uniform. But it must be remembered that this condition does not generally exist in large furnaces. Suppose, for instance, that it is required to find the temperature of the molten metal on the hearth of a furnace viewed through a thick layer of furnace gases, which are probably at a much higher temperature. It is evident that the radiation from the intervening flame may be much greater than that from the metal, and may introduce serious errors. The same objection applies with greater force to optical pyrometers, as the luminous radiation from gases may be of a highly selective character If, on the other hand, it is required to observe the temperature of metal in a ladle before casting, the surface of the metal must be cleared of scum, and it is necessary to know the emissive power of the metal or oxide exposed.

For scientific measurements of temperature by the radiation method, the thermopile, or bolometer, or radiomicrometer, previously calibrated by exposure to a black body at a known temperature, is directly exposed at a known distance to a known area of the source of radiation The required result may then be deduced in terms of the area and the distance. The use of extraneous optical appliances is avoided as far as possible on account of selective absorption For practical purposes, in order to avoid troublesome calculations and measurements, an optical arrangement is employed, either lens or mirror, in order to form an image of the source on the receiving surface. In Féry's mirror pyrometer, a mirror which is focused by the pinion, forms an image of the source on a disk, supported by wires of constantan and copper forming a thermocouple, connected by the brass strips to terminals. An observation hole in the wall of the furnace is sighted through an eyepiece, and is made to overlap the disk slightly. The rise of temperature of the junction is assumed to be proportional to the intensity of radiation, and is indicated by the deflexion of a delicate galvanometer connected to the terminals A lens may be substituted for the mirror at high temperatures, but it is necessary to allow for the selective absorption of the lens, and to a less extent for that of the mirror, by a special calibration of the scale

Assuming Wien's laws for the distribution of energy in the spectrum (*see* HEAT), the temperature of a black body may also be measured by observing (1) the wave-length corresponding to maximum intensity in the normal spectrum, which varies inversely as the absolute temperature, or (2) the maximum intensity itself, which varies as the fifth power of the absolute temperature, or (3) the intensity of radiation corresponding to some particular radiation or colour which varies as an exponential function of T, as given by Wien's formula. Methods (1) and (2) require elaborate apparatus and are impracticable except for purposes of scientific research. The *exact* application of method (3) is almost equally difficult, and is less certain in its results, but for optical purposes this method may be realized with a fair degree of approximation by the use of coloured glasses, and forms the basis in theory of the most trustworthy optical pyrometers.

Optical or Photometric Pyrometers.—The change of colour of a heated body from red to white with rise of temperature, and the great increase of intrinsic brilliancy which accompanies the change, are among the most familiar methods of estimating high temperatures. For many processes eye estimation suffices, but a much greater degree of accuracy may be secured by the employment of suitable photometers. In Mesuré and Nouel's pyrometric telescope, the estimation of temperature depends on observing the rotation of a quartz polarimeter required to reduce the colour of the radiation to a standard tint. It has the advantage of requiring no auxiliary apparatus, but, owing to the lack of a standard of comparison, its indications are not very precise. In the majority of photometric pyrometers, a standard of comparison for the intensity of the light, either an amyl-acetate or gasoline lamp, or an electric glow-lamp, is employed. The optical pyrometer of H. L.

Le Chatelier (*Comptes Rendus*, 1892, 114, p. 214) was one of the earliest, and has served as a model for subsequent inventors The standard of comparison is an amyl-acetate lamp, the flame of which is adjusted in the usual manner and viewed in the same field as the image of the source. The two halves of the field are adjusted to equality of brightness by means of a cat's eye diaphragm and absorption glasses, and are viewed through a red glass, giving nearly monochromatic radiation in order to avoid the difficulty of comparing lights of different colours Assuming Wien's law, the logarithm of the intensity of monochromatic radiation for a black body is a linear function of the reciprocal of the absolute temperature, and the instrument can be graduated by observing two temperatures; but it is generally graduated at several points by comparison with temperatures observed by means of a thermocouple.

The Wanner Pyrometer (*Phys Zeits*, 1902, p 112) is a modification of Konig's spectrophotometer, in which the two halves of the field, corresponding to the source and the standard of comparison, are illuminated with monochromatic red light polarized in planes at right angles to each other

The Féry Absorption Pyrometer (*Journ Phys*, 1904, p 32) differs from Le Chatelier's only in minor details, such as the replacement of the cat's eye diaphragm by a pair of absorbing glass wedges The principles of its action and the method of calibration are the same The pyrometers of Morse, and of L F C Holborn and F Kurlbaum depend on the employment of a glow lamp filament as standard of comparison, the current through which is adjusted to make the intrinsic brilliancy of the filament equal to that of the source When this adjustment is made the filament becomes invisible against the image of the source as background, and the temperature of the source may be determined from an observation of the current required Each lamp requires a separate calibration, but the lamps remain fairly constant provided that they are not overheated. To avoid this, the source is screened by absorption glasses (which also require calibration) in observing high temperatures. Except at low temperatures the comparison is effected by placing a red glass before the eyepiece. At low temperatures a special advantage of the glow-lamp as a standard of comparison is that it matches the source in colour as well as in brightness, so that the instrument is very sensitive

International Temperature Scale.—The following specification has been abridged from the first announcement issued by the U.S A Bureau of Standards in Oct 1928. The numerical values assigned to the basic fixed points chosen in addition to 0° and 100° as the foundation of the scale are as follows·—

B P of Oxygen at $p=760$ mm $t=182{\cdot}97°$Int.

The variation with pressure between 680 and 780 mm is given by

$$t=-182\ 97+0{\cdot}0126\ (p-760)-0{\cdot}0000065\ (p-760)^2$$

Similarly for the B.P. of Sulphur between 680 and 780 mm pressure,

$$t=444{\cdot}60+0\ 0909(p-760)-0\ 000048(p-760)^2$$

F P. of silver (free from O_2) $t=960\ 5°$Int

F.P. of Gold $t=1063°$Int.

The instruments available for interpolation lead to a division of the scale into four parts.

(a) from 0° C to 660° the temperature t is deduced from the resistance R_t of a standard platinum resistance thermometer by the formula

$$R_t=R_o(1+At+Bt^2).$$

The constants R_o, A, and B are to be determined by calibration at the ice, steam, and sulphur points, respectively. The purity and physical state of the platinum should be such that R_t/R_o shall not be less than 1·390 for $t=100°$, and 2·645 for $t=444{\cdot}6°$. (*Note.* This agrees with equation (21) above, which would naturally be employed for thermometers adjusted to read direct in degrees of temperature on the platinum scale denoted by *pt.*)

(b) From −190° to 0° C, the temperature t is deduced from the resistance R_t of a standard platinum resistance thermometer by means of the formula

$$R_t=R_o(1-At-Bt^2-C[t-100]t^3)$$

The constants R_o, A, and B are to be determined as specified above, and the additional constant C is determined by calibration at the oxygen point

The standard thermometer for use below 0° C must, in addition have a ratio R_t/R_o less than 0 250 for $t=-183°$

(c) From 660° to the gold point, the temperature t is deduced from the electromotive force e of a standard platinum versus platinum-rhodium thermocouple, one junction of which is kept at a constant temperature of 0° C while the other is at the temperature t defined by the formula, $e=a+bt+ct^2$. The constants a, b, and c are to be determined by calibration at the freezing points of Antimony, Silver and Gold, that for antimony being determined with a standard platinum resistance thermometer, since it lies within the range 0° to 660°, being about 630 5° for pure antimony when protected from access of oxygen.

The platinum of the standard thermocouple should be of the same purity as specified for a resistance thermometer The alloy is to consist of 90% platinum with 10% Rh The couple should develop an electromotive force e not less than 10·2 international millivolts nor more than 10 4 at the gold point

(d) Above the gold point the temperature t is determined by means of the ratio of the intensity J_2 of monochromatic visible radiation of wave-length λ cm, to the intensity J_1 of radiation of the same wave-length emitted by a black body at the gold point, by means of the formula

$$\log_e(J_2/J_1)=(1\ 432/\lambda)\ \{1/1336-1/(t+273)\}.$$

This equation is valid if $\lambda\ (t+273)$ is less than 0 3 cm degrees, the constant 1 432 representing the value assigned to Wien's constant of radiation in the same units, and 1336 being the absolute temperature at the gold point

It is expected that international thermometric conferences will be called by the International Committee on Weights and Measures, for the revision of this scale as occasion requires

Secondary Fixed Points on the International Scale.

B P. of solid Co_2	−78 5	F.P of Tin	231 85	F P of Zinc	410.45
F.P. of Mercury	−38 38	B.P of $C_6H_5\ _2CO$	305 9	F P of Antimony	630 5
F.P of Na_2SO_4	32 38	F P. of Cadium	320 9	F.P of Copper	1083
B P of Napthlene	217 96	F P of Lead	327 3	F P of Palladium	1555

Bibliography.—Most of the principles and methods of thermometry are described in text-books on heat, of which Preston's *Theory of Heat* may be specially mentioned For recent advances in thermometry the reader should consult the original papers The greater part of the recent work on the subject will be found in the publications of the Bureau International des Poids et Mesures de Sèvres (Paris), of the Reichsanstalt (Berlin), of the Bureau of Standards, U S A (Washington), and of the National Physical Laboratory (London), *Methods of Measuring Temperature* by Ezer Griffiths is well up to date and gives very full references to original papers (H L C)

THERMOPYLAE, a Greek pass leading from Locris into Thessaly between Mount Oeta and the Maliac Gulf; chiefly famous for the heroic defence by the Spartan king, Leonidas, with 300 soldiers against the Persian army of Xerxes advancing upon Greece in 480 (*See* Leonidas) Two other battles here are famous In 279 B.C Brennus and the Gauls were checked for several months by a Greek army under the Athenian Calippus, and in 191 Antiochus of Syria vainly attempted to hold the pass against the Romans under M'. Acilius Glabrio. In the time of Leonidas the pass was a narrow track (probably about 14 yd wide) under the cliff In modern times the deposits of the Spercheius have widened it to a breadth of 1½ to 3 m broad. The hot springs from which the pass derived its name still exist close to the foot of the hill There is one large spring used as a bath and four smaller ones, and the water, which is of a bluish green colour and contains lime, salt, carbonic acid and sulphur, is said to produce good effects in scrofula, sciatica and rheumatism.

See G. B. Grundy, *Great Persian War*, pp. 277–291 (1901).

THERMOSTAT. A device to regulate automatically the temperature produced by a heating apparatus; in some cases to maintain the temperature at a definite degree. While thermostats differ greatly in detail, their principle is always the same; they take advantage of the expansion produced by heat to control the source of heat They can be applied to boilers or heating apparatus of all sorts, whether fired by solid or gaseous fuel, or by electricity.
Thermostats may be summarized under two principal headings. (1) those in which the expanding medium is volatile fluid and (2) those in which the sensitive part is metallic.

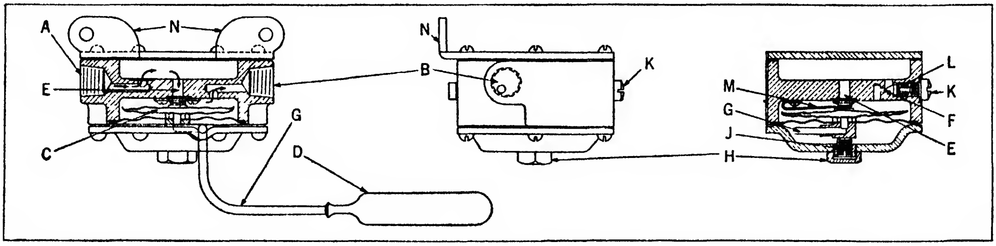

FIG. 1.—THERMOSTAT IN WHICH EXPANDING MEDIUM IS VOLATILE FLUID A FROM GAS SUPPLY LINE, B. GAS TO BURNER, C DIAPHRAGM, D. BULB, E MAIN VALVE, F BY-PASS VALVE (NEEDLE TYPE), G CAPILLARY, CONNECTING BULB TO DIAPHRAGM, H HEXAGONAL CAP SCREW, J ADJUSTING SCREW FOR LOWER OR HIGHER TEMPERATURE, K SEALING CAP SCREW, L. ADJUSTING SCREW FOR BY-PASS VALVE, M SPRING FOR OPENING MAIN VALVE; N. MOUNTING BRACKET

In either form, expansion or contraction with change of temperature affects fuel consumption and the production of heat.

In gas-fired hot water apparatus, in which a thermostat is commonly used, the regulators are worked by a capsule, containing volatile fluid, placed in close proximity to the water being heated; as the temperature rises the fluid expands and reduces the size of the passage through which the gas is conveyed to the burners. Figure 1 shows a section through such a thermostat In connection with this apparatus a small orifice or by-pass is provided, around the main gas passage, to maintain a small gas flame whatever condition prevails in the main passage. This prevents the gas from being entirely extinguished

The rod thermostat is another form of thermostat often used in gas apparatus. It is of very simple construction As the temperature rises the tube enclosing the rod lengthens, thereby drawing the rod outward and reducing the gas-way.

When either form of thermostat is used, the process is reversed when water is drawn off Upon cold water entering the apparatus the contraction of the thermostat allows more gas to pass, so that the temperature again rises. (*See* REGULATION, AUTOMATIC)

THÉROIGNE DE MÉRICOURT, ANNE JOSÈPHE (1762–1817), a Frenchwoman who was a striking figure in the Revolution, was born at Marcourt (from a corruption of which name she took her usual designation), Luxembourg, on Aug. 13, 1762. She was the daughter of a farmer, Peter Théroigne She was educated in the convent of Robermont. She was quick-witted, handsome, intensely passionate in temper, and had a vigorous eloquence, which she used with great effect upon the mobs of Paris during the few years of her life (1789–93) which are of historical interest She left her home on account of a quarrel with her stepmother. In her career as courtesan she visited London (1782), and Genoa as a singer (1788) In Paris on the outbreak of the Revolution, she was surrounded by a coterie of well-known men, chief of whom were Pétion and Desmoulins.

She was again in Paris in Jan 1792, where she often spoke in the clubs. Even in the National Assembly she would violently interrupt the expression of moderatist views. Known as "la belle Liégoise," she wore a riding habit, a plume in her hat, a pistol in her belt and a sword at her side, and excited the mob by violent harangues. Associated with the Girondists and the enemies of Robespierre, she became in fact the "Fury of the Gironde." She commanded in person the III corps of the so-called army of the faubourgs on June 20, 1792, and shares a heavy responsibility for the riots of Aug. 10. She took no part in the September massacres, and, moderating her conduct, became less popular from 1793. Towards the end of May the Jacobin women seized her, stripped her naked, and flogged her in the public garden of the Tuileries. The following year she became mad; she died at La Salpetrière on June 9, 1817

See E. and J de Goncourt, *Portraits intimes du XVIIIe siècle* (2 vols, 1857–58); M Pellet, *Étude historique et biographique sur Théroigne de Méricourt* (1886); L. Lacour, *Les Origines du féminisme contemporain Trois femmes de la Révolution* (1900), Vicomte de Reiset, *La Vraie Théroigne de Méricourt* (1903); and the play *Théroigne de Méricourt* of M Paul Hervieu, produced at the Théâtre Sarah Bernhardt in 1902.

THERSITES, the ugliest man in the Greek camp before Troy, a railing demagogue (*see* Homer, *Iliad* ii, 212), was a relative of Diomedes (*q v*)

THESEUS was the great hero of Attic legends and the son of Aegeus, king of Athens, and Aethra, daughter of Pittheus, king of Troezen, or of Poseidon and Aethra The legend relates that Aegeus, being childless, went to Pittheus, who contrived that Aegeus should have intercourse with Aethra, who in due time brought forth Theseus On reaching manhood Theseus was sent by his mother to Athens He encountered many adventures on the way. First he met and slew Periphetes, surnamed Corynetes (Clubman). At the isthmus of Corinth dwelt Sinis, called the Pine-Bender, because he killed his victims by tearing them asunder between two pine-trees. Theseus hoisted the Pine-Bender on his own pine-tree. Next Theseus despatched the Crommyonian sow (or boar). Then over a cliff he flung the wicked Sciron, who used to kick his guests into the sea, while perforce they washed his feet. In Eleusis Theseus wrestled with Cercyon and killed him. Later he slew Procrustes, who fitted all comers to his only bed by lopping or racking them to the right length He found his father married to Medea, who had fled from Corinth Being a witch, she knew Theseus before his father did, and tried to persuade Aegeus to poison his son; but Aegeus recognized him Theseus was now declared heir to the throne, and the Pallantids[1], who had hoped to succeed the childless king, conspired against him, but he crushed the conspiracy He then attacked the fire-breathing bull of Marathon and brought it alive to Athens, where he sacrificed it to Apollo Delphinius. Next came the adventure of the Cretan Minotaur (q v.).

While Theseus was on his way to Crete, Minos, wishing to see whether Theseus was really the son of Poseidon, flung his ring into the sea. Theseus dived and brought it up, together with a golden crown, the gift of Amphitrite. He landed on the return voyage at Delos, and there he and his comrades danced the crane dance, whose complicated movements were meant to imitate the windings of the Labyrinth. In historical times, this dance was still danced by the Delians round the Altar of Horns. Theseus had promised Aegeus that, if he returned successful, the black sail with which the fatal ship always put to sea should be exchanged for a white one. But he forgot his promise; and when Aegeus, from the Acropolis at Athens, descried the black sail out at sea,

[1]The sons of Pallas, the brother of Aegeus. Aegeus and Poseidon are quite possibly one and the same.

he flung himself from the rock and died. Hence, at the festival which commemorated the return of Theseus there was always weeping and lamentation. Theseus now carried out the union of the various Attic communities into a single State. He extended the territory of Attica to the isthmus of Corinth.

He transformed the Isthmian ceremony in honour of Melicertes by adding games in honour of Poseidon. Alone, or with Heracles, he captured the Amazon princess Antiope. Thereafter

the Amazons attacked Athens. Antiope fell fighting on the side of Theseus. By her he had a son, Hippolytus (q.v.). Theseus is also said to have taken part in the Argonautic expedition and the Calydonian boar-hunt. He compelled the Thebans to give up the unburied bodies of the Seven (*see* ANTIGONE).

The famous friendship between Theseus and Peirithous, king of the Lapiths, originated when Peirithous heard of the strength and courage of Theseus, and desired to put them to the test. Accordingly, he drove away from Marathon some cows which belonged to Theseus. The latter pursued, but when he came up with the robber the two heroes were so filled with admiration of each other that they swore brotherhood. At the marriage of Peirithous, a fight broke out between the Lapiths and Centaurs (q.v.). Theseus and Peirithous now carried off Helen (q.v.). He now descended to the lower world with Peirithous, to help his friend to carry off Persephone. But the two were caught and confined in Hades till Heracles came and released Theseus. When Theseus returned to Athens, he found that a sedition had been stirred up by Menestheus, a descendant of Erechtheus, one of the old kings of Athens. Failing to quell the outbreak, Theseus in despair sent his children to Euboea, and after solemnly cursing the Athenians sailed away to the island of Scyrus, where he had ancestral estates. But Lycomedes, king of Scyrus, took him up to a high place, and killed him by casting him into the sea. His ghost was said to have appeared in the Athenian ranks at Marathon. When the Persian war was over, the Delphic oracle bade the Athenians fetch the bones of Theseus from Scyrus and lay them in Attic earth. This was done, in 469, by Cimon. His chief festival, called Theseia, was on the 8th of the month Pyanepsion (Oct. 21), but the 8th day of every month was sacred to him.

The well-preserved Doric temple to the north of the Acropolis at Athens, commonly known as the Theseum, is certainly not his shrine. There were several (according to Philochorus, four) temples or shrines of Theseus at Athens.

(1921); Stending in Roscher's *Lexikon, s.v.* (good bibliography) also O. Gruppe, *Griechische Mythologie,* i. pp. 581–608 (Munich, 1898).

THESMOPHORIA. A very ancient festival, celebrated by women in many parts of the Greek world (as Attica, many places in the Peloponnesos, Boeotia, several islands, the coast of Asia Minor, Cyrene, Italy and Sicily, but not generally among the Dorians) in honour of Demeter *Thesmophoros,* which does not mean, as the ancients usually supposed, *legifera Ceres* (Virg., *Aen.,* iv. 57), since the festival can in no way be connected with the bringing or establishing of laws or customs (θεσμοί). It is possibly "bringer of treasure or wealth," an obsolete sense of θεσμός, of which a few traces remain; or perhaps better (Frazer, *Enc. Brit.* 9th ed., Nilsson, *Griech. Fest.*, p. 324), the name Thesmophoria is the primary one, from which the epithet of the goddess is derived, and it means "the carrying of things laid down," the radical meaning of θεσμός, referring to the curious fertility-charms described below.

As no men were admitted to the rites, and in any case they were largely secret (for the reasons *see* MYSTERY), we have nothing like a full description (but *see* H. J. Rose, *Primitive Culture in Greece,* 1925).

The celebrants were women who seem to have been at least generally married, and who must be free. They observed chastity for some days (nine, according to Ovid, a likely number enough considering its magical connotations), and also abstained from certain foods; thus, they must not eat pomegranate-seeds. The festival itself lasted three days, although in Attica it was lengthened by the addition of other celebrations of a similar character, the Stenia and the Halamusian Thesmophoria, making five days in all, Pyanopsion 10–14. But the original days were Pyanopsion 12–14 only, *i.e.*, about the beginning of October, and shortly after the Pyanopsia (*q.v.*). The days were called respectively *Anodos* (or *Kathodos*), *Nesteia*, *Kalligeneia*. *Anodos* (ascent) is often taken to mean the "going up" of the women to the Thesmophorion, or precinct of Demeter; but this does not explain why the day should also be called *Kathodos*, or descent. As the name of the second day, which signifies "fasting," describes what the celebrants then did, it is plausible to take the first day as having been called Ascent and Descent, and to connect it with the rite known to have been performed at some time in the festival. Pigs were thrown into an underground chamber, called a *megaron;* they were probably alive, but the text (Clement of Alexandria, *Protrept.*, p. 14 Pott.) is corrupt and uncertain. At all events they were left there until such parts of them as were not eaten by the guardian snakes of these underground sanctuaries had had time to rot. The remains were then brought up by certain women who had observed chastity for three days and were called ἀντλήριαι or drawers up—the verb ἀντλεῖν means to pump or draw off water, and it is strange that its cognate noun should be used in this way. These women also carried, or some of the celebrants did, certain well-known symbols of fertility, including pine-cones and "figures made of flour of wheat, in imitation of the shapes of serpents and of men." The remains of the pigs were laid on an altar, and if taken and mixed with seed were believed to ensure a good crop. Apparently the figures, like the pigs, were thrown into the chasms, but our authority here (a scholiast on Lucian, first published by Usener in *Rheinisches Museum*, xxv p. 548) is both confused and manifestly corrupt; he seems to be confusing the Thesmophoria with a quite different festival, the Arrhephoria. If, however, pigs, pine-cones, figures and all were thrown into the *megara* and "pumped" out again, it is very intelligible magic. These objects are all, in their nature, connected with fertility—a fertile beast, a seed-vessel, a preparation of grain shaped like a creature supposed to be full of earth-magic (the serpent) and like a man, perhaps a phallic figure. They are then put into a holy place, left there to acquire additional *mana* from the sacred surroundings and the touch of the sacred serpents, real or imaginary, who live there, and finally taken out again by pure agents, whose chastity has, so to speak, insulated them. Finally, they are laid on a holy altar, whence they are taken, heavily charged now with potency, and used to bring the blessing of fertility. To mix all manner of magical things with seeds to make them sprout better is a widespread savage custom, the Khonds, for instance, bury the flesh or ashes of a human victim (*meriah*) in their fields, or did so until the British Government stopped their horrible practices.

The ancients tried to explain all these matters as commemorations of the abduction of Kore; but it is rather the legends which have grown out of the ritual, now no longer understood. In modern times it has been found possible to conjecture a reason for them; but it is to be remembered that, owing to the fragmentary state of our knowledge, the above is offered as a conjecture only, especially as regards the date of the rite.

The *Nesteia* is easily enough explained; we know that the

women fasted, sitting upon the ground Fasting is a common piece of agricultural magic, and contact with the ground is also common; for a Greek parallel we may refer to the ancient Dodonaean priesthood of the *Selloi*, who slept on the earth (Homer, *Il.*, xvi 235). The third day, *Kalligeneia*, is "the fair birth." We need not take it as originally referring to anyone so definite as Kore; it rather indicates the happy issue of all this magic, and doubtless of much more which we do not know, in the fertility of the ground and doubtless of men and beasts as well It remains only to add that the Thesmophoria, or at least a great part of it, was carried out at night by torchlight, and that it was accompanied by ceremonial coarse abuse (αἰσχρολογία) between the women; again a common means of promoting fertility.

THESPIAE, an ancient Greek city of Boeotia, on level ground commanded by the low eastward spurs of Mount Helicon The deity most worshipped at Thespiae was Eros, whose primitive image was an unwrought stone. The town contained many works of art, among them the Eros of Praxiteles, dedicated by Phryne in her native place, one of the most famous statues in the ancient world It was carried off to Rome by Caligula, restored by Claudius, and again carried off by Nero There was also a bronze statue of Eros by Lysippus The Thespians also worshipped the Muses, and celebrated a festival in their honour in the sacred grove on Mount Helicon Remains of the ancient citadel are still to be seen, solidly and regularly built. To E and S foundations bear witness to the extent of the ancient city The neighbouring village Eremokastro, on higher ground, was thought by Ulrichs to be probably the site of ancient Ceressus In 1882 there were discovered, about 1,200 yd east of Eremokastro, on the road to Arkopodi (Leuctra), the remains of a tomb of the 5th century B C., with a colossal stone lion, probably that of the Thespians who fell at Plataea

History.—Thespiae figures chiefly as an enemy of Thebes, whose centralizing policy it had all the more to fear because of the proximity of the towns During the Persian invasion of 480 B C it stood almost alone among Boeotian cities in serving the national cause. Seven hundred Thespians accompanied Leonidas to Thermopylae and of their own free will shared his fate The remaining inhabitants, though their city was burnt by Xerxes, furnished 1,800 men to the Greek army at Plataea In 424 B C. the Thespian contingent at Delium sustained heavy losses, and in the next year the Thebans took advantage of this to accuse Thespiae of friendship towards Athens and to dismantle its walls In 414 they interfered again to suppress a democratic rising In the Corinthian war Thespiae sided with Sparta, and between 379 and 372 repeatedly served the Spartans as a base against Thebes In the latter year they were reduced by the Thebans and compelled to send a contingent to Leuctra (371) It was probably shortly after this battle that the Thebans destroyed Thespiae and drove its people into exile Later the town was rebuilt and in 171 B C, true to its policy of opposing Thebes, sought the friendship of Rome.

THESPIS, Greek poet, of Icaria, in Attica (6th cent. B.C.), generally considered the inventor of tragedy, flourished in the time of Peisistratidae. According to Diogenes Laërtius (iii. 56), he introduced for the first time in the old dithyrambic choruses a person distinct from the chorus, who conversed with the leader, and was hence called ὑποκριτής ("answerer") His claim to be regarded as the inventor of tragedy in the true sense of the term depends upon the extent to which this person was really an "actor." (*See* Drama) Suïdas gives the titles (of doubtful authenticity) of several of his plays (not confined to the legends of Dionysus, but embracing the whole body of heroic legends), but the fragments quoted in various writers as from Thespis (*see* Nauck [*Tragic Fragments*]), are probably forgeries by Heracleides of Pontus The statement of Horace (*Ars Poetica,* 276) that Thespis went round Attica with a cart, on which his plays were acted, is due to confusion between the origin of tragedy and comedy, and a reminiscence of the scurrilous jests which it was customary to utter from a waggon (σκώμματα ἐξ ἁμάξης) at certain religious festivals A. and M Croiset (*History of Greek Literature*, Eng. tr, 1904), who attach more importance to the part played by Thespis in the development of tragedy, accept the testimony of Horace. According to them, Thespis, actor and manager, transported his apparatus on a cart to the deme in which he intended to produce his drama, formed and trained a chorus, and gave a representation in public

See Drama; and W. Christ, *Griechische Litteraturgeschichte* (1898).

THESSALONIANS, EPISTLES TO THE, two books of the New Testament. These earliest extant letters of Paul mark the beginnings of Christian literature. Fortunately we can date them as written from Corinth early in A.D. 50, under the circumstances of the life of Paul (*q v.*) related in Acts xvii. The designation "Missionary Epistles" is sometimes applied to the pair because they stand apart from the "Major" four addressed to Galatia, Corinth, and Rome, being as yet unaffected by the Judaizing reaction. They thus afford a simpler view of the normal type of gospel preached by Paul in Gentile territory, with the reactions it encountered. The designation "Eschatological" would be more distinctive, because doctrinally they chiefly reflect the difficulties raised among Greek converts by the proclamation of "Christ and the resurrection" (Acts xvii. 22–32, *cf* I, i 9–10). The drama of a return of the glorified Jesus to judgment and renewal of the world, represented in such books of "Prophecy" as the Revelation of John (*q v*), was taken over by the primitive Church from contemporary Jewish Apocalypse, but in Paul's letters and in Greek Christianity generally is gradually modified and pruned of its crudities. We should not fail to note that in Acts xv. 32 Silas, or Silvanus, whom Paul here associates with himself as joint author, is specifically called a "prophet "

First Epistle.—Both Thessalonian epistles are replies to communications from that newly founded church, probably not in oral form alone I., i–iii. reviews Paul's whole relation to it by way of defence against insinuations from outsiders ascribing his missionary activities to selfish motives Paul reminds his converts that, when among them, he had not even called for the respect and support which were his due, but had depended for support on his own labour, supplemented by voluntary gifts from churches previously founded, showing toward them only the care and solicitude of a parent He had been driven out by the jealous hostility of the Jews, who here showed that bitter antagonism shown against the prophets of old, against Jesus, and the mother church in Jerusalem; but he still hopes to return If his prayers and hopes are frustrated it will be due only to the machinations of Satan, not any failure on his part A practical section follows in iv 1–12 urging increased efforts against sexual impurity (a besetting sin of the Greek churches), greater brotherly love, and a life of orderly industry forestalling possible charges from outsiders of idle fanaticism Practical advice leads over to doctrinal instruction Individuals have been disturbed in their faith by the death of some members of the brotherhood before the expected Coming Paul re-assures them by citing a "word of the Lord " This is not, as sometimes imagined, a transmitted report of some saying of the earthly Jesus, whose authentic teachings are of very different stamp, but a message from the glorified "Lord" in "the Spirit," that is, through the type of "prophecy" illustrated in the messages of Jesus "in the Spirit" to the churches of Asia (Rev. i 1 *ff.*). In I., iv. 13–18 Paul applies such parts of this primitive apocalypse as will serve to "comfort" those in danger of losing their Christian hope, and passes at once in v. 1–11 to further practical exhortation to watch and be sober as children of the light about to dawn, not overtaken like the sinful world by the Coming of the Lord to judgment. After direction to leaders and laity alike to co-operate toward a blameless and orderly communal life, with instructions that the letter be read in public assembly, Paul pronounces his apostolic benediction.

Second Epistle.—The second epistle continues the correspondence after an interval so brief that outward conditions appear unchanged, while leading features of the preceding letter are continued and accentuated In particular the unfamiliar Jewish eschatology is explained and developed. Chapter i. repeats with further detail the proclamation of the Coming of Christ to judgment of I, i 10, and justifies the doctrine of "wrath" against persecuting unbelievers in contrast with "rest" and "glory" for the saints. But in ch ii. a new factor appears. Before the hoped-for Advent the "mystery of lawlessness" now at work in the world must culminate in a counter-manifestation of Satan's power. An Antichrist (*q.v*) will appear "in the temple of God" claiming divine honours there after the manner of the desecration of Antiochus, self-styled "God-manifest," predicted in Daniel. The programme of redemption will begin by the slaying of Antichrist by the breath of the Lord's mouth at his Coming. Momentarily Satan is held in check by Roman power. The closing chapter (iii) resumes the admonitions of I., v. 12–28, re-enforcing disciplinary measures to be taken against the "disorderly"

Authenticity.—Objections once urged against the authenticity of I. have lapsed, but some still question II Slight changes of diction, usually toward more emphatic form in II., need not detain us Doubts aroused by the suspicions expressed in II, ii 2 and iii 17, are not warranted Actual circulation of spurious letters during the lifetime of the reputed author is indeed improbable But this is not implied Paul has heard of misrepresentations of his teaching and wishes to remove all conceivable excuse for it. The strong language of II, ii. 2 against an alleged Pauline doctrine of the Day of the Lord as "now present" no more presupposes actual utterance by "spirit" (*i e*, "prophecy"), or by "word" (of Jesus), or "by letter purporting to be from us" than the stronger language of Gal i 8 presupposes actual anti-Pauline preaching by "an angel from heaven" However, spurious epistles were common enough in Paul's time It is interesting to see how he already guards himself against this possibility by the device later exemplified in Gal vi 11–18 and illustrated by many actual documents among the Oxyrhynchus papyri, by attaching to the dictated letter an autographed farewell "in mine own hand"

Serious objections to the authenticity of II. are of two kinds, (1) from its similarity to I both in formal arrangement of material and in language, (2) from its unexpected attachment of the Antichrist doctrine to Paul's eschatology.

The similarity of material and structure is probably sufficient to prove dependence, possibly even literary dependence. But why not? Intrinsic probability as well as the known practice of the ancients suggests that a copy of I. would be available at Corinth for Paul's use in continuing the correspondence. There remains thus, as the only serious objection to the authenticity of II its belated supplement to Pauline eschatology The Antichrist doctrine, if not actually opposed to his teaching elsewhere, is almost unmentioned (but *cf* I Cor xv. 24–28 and "Belial" in II. Cor. vi 15) Did Paul forget to mention this preliminary crisis when seeking in I, v 1–11 to allay excitement at Thessalonica over the expected immediate Coming and to restore orderly industry? Was the working of the "mystery of iniquity" an afterthought?

For answer we must consider the occasion for his introducing the (apocalyptic) "word of the Lord" cited in I, iv. 15–17. It was to restore the hope of certain converts grieved by recent bereavement, and professedly contains but a part of the teaching. Paul purposely limited himself to the single lesson in I, v 1–11 of watchfulness in view of the uncertainty of the hour. But his readers, reminded of the revelation, seem now to feel that a little more definite information concerning the "times and seasons" would greatly help. If the Antichrist paragraph of II be read as in reply to an intimation of this kind, probably by letter, while the fact is kept in mind that in both letters the subject is repeatedly declared to be no new doctrine but something preached from the beginning by Paul and his fellow-missionaries, it will be easier to realize that it is not an afterthought with which we are here dealing, but rather something earlier and primitive, brought now to the surface by further development of the subject

Bibliography.—The most careful study of I. and II. Thess., with full bibliography will be found in the *International Critical Commentary* by J E Frame, 1912. Similar ground is taken by E von Dobschütz in Meyer's Commentary (1909) and by M Dibelius in Lietzmann's *Handbuch* (1911), also by Geo Milligan (1908) and J. Moffatt (in *Expositor's Gr. Test.*, 1910). Against the authenticity of II. *see* H J. Holtzmann (*Einl* 1892 and *Zeitschr. f. ntl Wiss.*, 1901), Pfleiderer, *Urchristenthum* (1902), and Wrede, *Echtheit des zweiten Thessalonicherbriefes* (1903). On the relation to Synoptic apocalypse *see* Bacon, *The Gospel of Mark* (1925) (B. W Ba)

THESSALY, a district of northern Greece, between Macedonia and the Hellenic countries towards the south, and between upland Epirus and the Aegean It forms an irregular square of about 60 m in each direction, for the most part level, but with well-marked boundaries, the Cambunian mountains on the north, Othrys on the south, the massive chain of Pindus, the backbone of this part of Greece, on the west, while at the north-eastern angle is Olympus, separated by the gorge of Tempe (*q v*) from the coast range of Ossa and Pelion, standing in a continuous line to the south-east Three peaks of Pindus are over 5,000 ft, and Olympus, Ossa and Pelion reach respectively 9,790, 6,398 and 5,350 feet The country within these limits is drained by numerous confluents, which pass into the sea through the gorge of Tempe

Through Thessaly, therefore, lie all land routes between peninsular Greece and the north An important pass from Petra in Pieria debouches west of Olympus on the plain north of Larissa By this Xerxes entered (Herodotus vii 173), and when the Greeks heard of this passage, they gave up their defence of Tempe. The main communication with Epirus passed over Mount Lacmon by the upper Peneius to Aeginium in the north-west angle By this route Julius Caesar arrived before the battle of Pharsalia Another pass, farther south by Gomphi, leads to the Ambracian gulf The great southern pass of Coela crosses Mount Othrys nearly north of Thermopylae

Though Thessaly is the most level district of Greece, it is composed of sections, divided by ranges of hills, Upper Thessaly, to the west and south-west, contains the higher course of the Peneius and all tributaries from the south—Enipeus, Apidanus, Onochonus and Pamisus Lower Thessaly, from the central ridge west of Larissa to the foot of Ossa and Pelion, is inundated by the Peneius, the flood-water forming the Lake Nessonis, and, when that is full, pouring into Lake Boebe The chief city of the lower Thessaly was Larissa, in the south at the pass of Coela is another plain, containing a small lake, formerly called Xynias, and low hills separate this from the town of Thaumaki, which overlooks the main upper plain "like a vast sea" (Livy xxxii 4) The Plain of Pharsalia, intersected by the Enipeus, lies north-east of this, and still farther another battlefield, Cynoscephalae The political divisions follow the physical, Pelasgiotis being the lower plain of the Peneius, Hestiaeotis and Thessaliotis respectively the north and the south portions of the upper, the fourth, Phthiotis, towards the south-east, was geographically separated by the watershed of Mt Othrys and its north-east spurs. The landlocked Pagasaeus Sinus (Gulf of Volo), extends from Pagasae at its head to Aphetae at its narrow outlet, where the chain of Pelion turns at right angles to south-west in broken ridges, while on the opposite side rise the heights of Othrys In the heroic age Phthiotis was the legendary birthplace of Greek navigation in the story of the Argonauts Hence Achilles came and, according to Thucydides (i. 3), it was the cradle of the Hellenes Iolcus, the centre of many legends, is near the modern Volo Near Iolcus, later, Demetrius Poliorcetes founded Demetrias, called by Philip V. of Macedon one of the "fetters of Greece," Chalcis and Corinth being the others.

The history of Thessaly is closely connected with its geography. From the earliest times Thessaly has had a separate history controlled by its situation. The fertility of the land offered a temptation to invaders, and was thus the primary cause of early migrations. Its first Neolithic culture combined Danubian characters with elements from the "Tripolje" culture of Ukraine; a second phase reinforces the latter elements, at Dimini near Volo. Then long decadence resulted from the spread, first of "Helladic," then of "Minyan" culture from the south. Finally, just as Mycenaean exploitation was beginning in the 12th century, fresh

northern invaders from Macedonia wrecked all At this point language and legend supplement archaeology. Thessalian Greek is of the Aeolic group, akin to Boeotian; but between lie the "West Greek" dialects of Phthiotis, Malis, and Doris, subsequently intruded Aeolic genealogies go back to the early part of the 14th century, whereas the Doric and West Greek expansion is referred to the 12th. Tradition brought both Thessalians and Boeotians from Arne in the north-west, imposing powerful aristocracies on the older inhabitants, who retained political coherence only among the marginal hills in Perrhaebia, Magnesia, and the like. The rich lowlands were the natural home of powerful families such as the Aleuadae of Larissa and the Scopadae of Crannon, and the absence of elevated positions was unfavourable to the foundation of cities, which might have fostered freedom and democracy The plains, also, were suited to the breeding of horses, and consequently the force in which the Thessalians were strong was cavalry, a kind of troops usually associated with oligarchy. The wealth and the semi-Hellenic character of the people (for, in race, as in geographical position, the Thessalians held an intermediate place between the Macedonians and the southern Greeks) held them aloof from national sentiment, and at the time of the Persian wars the Aleuadae joined the enemy United, as under Alexander and Jason, of Pherae, in the 4th century, the Thessalians were formidable, but they seldom combined for long, and consequently had little influence in Greece From the 4th to the 2nd century they were usually vassals of Macedon

For several centuries during the middle ages Rumanian immigrants formed so large a part of the population of Thessaly that that district was called by the Byzantine writers Great Wallachia (Μεγάλη Βλαχία); the Jewish traveller, Benjamin of Tudela, so describes it in the latter half of the 12th century Now, only a few Vlach (Ruman) colonies remain, principally on the west of Olympus and in some gorges of Pindus The Turkish conquerors settled in the larger towns and in great ranches The Greeks form so large a majority that, even while the country belonged to the Ottomans, Greek was the official language Thessaly was ceded to the Greek kingdom by the Porte in 1881 Since that time its prosperity has greatly increased The port of Volo, almost the only outlet of trade, has a steamer service to Athens Railways run· (1) from Volo by way of Velestino (ancient Pherae) to Larissa (*q v.*); (2) from Velestino to the west by Phersala (Pharsalos), Domokos (Thaumaki), Karditsa and Trikkala (Trika), to Kalabaka (Aeginium), in the upper valley of the Salambria (Peneius); (3) the main line from Athens to Salonika enters Thessaly by the Coela pass west of Othrys, reaches Larissa, and proceeds by the gorge of Tempe and the sea front of Olympus Thessaly is essentially an agricultural and pastoral district

THETFORD, a market town and municipal borough of England, mostly in the south-west of Norfolk, but partly in Suffolk, 91 m N.N.E. from London by the L N E R Pop (1921) 4,700. In the time of Edward III. the town had twenty churches and eight monasteries There are now three churches principally of Perpendicular flint work, and a few monastic remains, the chief being two gate-houses. The most important relic of antiquity is the Castle Hill, a mound 1,000 ft. in circumference and 100 ft. in height. The grammar school was founded in 1610. In King Street is the mansion-house occupied as a hunting-lodge by Queen Elizabeth and James I. Brewing and tanning are carried on; and there are also manure and chemical works. The town is governed by a mayor, 4 aldermen, and 12 councillors. Area, 7,096 acres

Tradition tells that Uffa, who probably threw up the earthworks called the Castle Hill, established the capital of East Anglia here about 575. In 1290 its principal officers were a mayor and coroner, afterwards assisted by eight burgesses, whom Henry VIII. increased to ten. The town, never very prosperous since the Conquest, had then fallen into great decay, but the petitions of the burgesses for a charter were not heeded till 1573 when Elizabeth incorporated it under a mayor and common council. This charter, restored in 1692 after its surrender to Charles II, remained in force till 1835 when the borough was re-constituted.

See A L Hunt, *Capital of East Anglia* (1870); T. Martin, *History of Thetford* (1779).

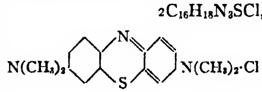
THETIS, in Greek mythology, daughter of Nereus, wife of Peleus and mother of Achilles The chief of the 50 Nereids, she dwelt in the depths of the sea with her father and sisters When Dionysus leaped into the sea to escape from the pursuit of Lycurgus, king of the Thracian Edones, and Hephaestus was flung out of heaven by Zeus, both were kindly received by Thetis. Again, when Hera, Athena, and Poseidon threatened to bind Zeus in chains, she sent the giant Aegaeon, who delivered him out of their hands She was married against her will to Peleus (*q v ; see* also ACHILLES). Thetis is used by Latin poets simply for the sea.

THEUNIS, GEORGES (1873–), Belgian statesman, was born at Montegnée, near Liége, on Feb. 28, 1873. In Jan 1916 he attended the Inter-Allied Relief Commission in London and in 1919 represented Belgium on the Reparations Commission In 1920 he became finance minister in Carton de Wiart's coalition ministry, the aims of which Government were first to settle the reparations question, with due regard to Belgium's prior claim and secondly to maintain the entente between the Allies Theunis represented Belgium at the Inter-Allied Conferences of San Remo 1920, London 1924 and Paris 1925, which resulted in the adoption of the Dawes Plan and a corresponding inter-Allied settlement His home policy was to place Belgian finance on a sound basis and to reconstruct the devastated regions His cabinet resigned in April 1925, after the elections in which the democratic parties triumphed In Aug 1925 Theunis was sent by his Government to Washington to discuss the question of the Belgian debt to U S A This mission resulted in an agreement which was submitted to the parliaments of the two countries Theunis presided over the World Economic Conference at Geneva in 1927, he was also chairman of the permanent consultative economic committee formed at the League of Nations to carry out and continue the work of the conference

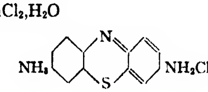
THEURIET, CLAUDE ADHÉMAR ANDRÉ (1833–1907), French poet and novelist, was born at Marly-le-Roi The best of his novels are *Le mariage de Gérard* (1875); *Raymonde* (1877); *Le fils Maugars* (1879); *La maison des deux Barbeaux* (1879); *Sauvageonne* (1880), *Reine des bois* (1890); *Villa tranquille* (1899); *Le manuscrit du chanoine* (1902). Theuriet died on the 23rd of April 1907

THIAZINES, in organic chemistry are compounds containing a ring system of one sulphur atom, one nitrogen atom and four carbon atoms. The most important thiazine is methylene-blue (formula I), a basic colouring matter employed in dyeing and printing on cotton mordanted with antimonyl tannate It is also used as a microscopic stain and as a reagent in bacteriological and histological researches. Methylene-blue was first discovered by H. Caro in 1876, who prepared it by oxidising *as*-dimethyl-*p*-phenylenediamine (obtained from *p*-nitrosodimethylaniline) with ferric chloride in presence of hydrogen sulphide The preparation was rationalised by A Bernthsen in 1887 who converted dimethyl-*p*-phenylenediamine into its thiosulphonic acid and oxidised this intermediate with chromic acid in the presence of a molecular proportion of dimethylaniline Methylene-blue is frequently sold in the form of its zincichloride,

$$2C_{16}H_{18}N_3SCl, ZnCl_2, H_2O$$



(I)



(II.)

A simpler member of the thiazine group is Lauth's violet (formula II), prepared from *p*-phenylenediamine by Caro's method of oxidation or from thiodiphenylamine by successive dinitration, reduction and oxidation (Bernthsen). The thiazine series of dyes also includes acidic colouring matters such as Brilliant Alizarin

Blue, prepared by condensing β-naphthaquinone-6-sulphonic acid with the thiosulphonic acid of a dialkyl-*p*-phenylenediamine For further information *see* the Colour Index of the Society of Dyers & Colourists (Edited by F. M Rowe, 1924).

THIAZOLES, in organic chemistry, a series of compounds containing five-membered rings of one nitrogen, one sulphur and three carbon atoms The most prominent thiazole derivative is the dyestuff, primulin, discovered by A G Green in 1887, which dyes unmordanted cotton in yellow shades. The dyed fabric can be treated with nitrous acid, when the dye is diazotised (*see* DIAZO-COMPOUNDS) so that varying shades of red, brown and claret are produced on dipping the prepared material into solutions of developers (β-naphthol, resorcinol, α-naphthylamine, etc)

When thiourea and chloroacetaldehyde, or preferably dichloroether, $CH_2Cl\,CHCl\,O{\cdot}C_2H_5$, are condensed in aqueous solution, 2-aminothiazole (I) is formed and this pale yellow crystalline base (m p 90° C) on treatment with nitrous acid and alcohol

(I)  (II)

loses its amino-group for hydrogen giving rise to thiazole itself (II), which is a colourless liquid boiling at 117° C and smelling like pyridine (Traumann, 1888)

When *p*-toluidine and sulphur are heated at 200° C, a complex product known as "primulin base" is obtained which consists mainly of the following thiazole derivative

This product when sulphonated to render it soluble in water and converted into its sodium salt is primulin (*See* DYES, SYNTHETIC) (G T M)

THIBAUT (or THEOBALD) **IV.** (1201–1253), count of Champagne and Brie, and king of Navarre, French poet, was born at Troyes in 1201 His father, Thibaut III of Champagne died before his son's birth, and his mother, Blanche of Navarre was compelled to resign the guardianship of the young prince to Philip Augustus, king of France, but there is little doubt that the child was acquainted with Chrétien de Troyes and the other trouvères who found patronage at the court of Champagne Thibaut's verses belong to what is called "courteous" poetry, but they have a personal note that distinguishes them from mere exercises They are addressed to Blanche of Castille, the wife of Louis VIII, and Thibaut's relations with her have been the subject of much controversy The count took part with Louis in the crusade against the Albigenses, but in 1226, with no apparent reason, left the king and returned to Champagne Three months later Louis died under doubtful circumstances, and Thibaut was accused by his enemies of poisoning him

The real reason for Thibaut's desertion appears to have been a desire to consolidate his position as heir-apparent of Navarre by an alliance with the disaffected nobility of the south of France, but from this confederation Blanche was skilful enough to detach him The resentment of the league involved him in a war in which Champagne was laid waste, and his capital saved only by the royal intervention In 1234 he succeeded his uncle, Sancho VII, as king of Navarre, and from this period date his most fervent songs in praise of his lady The crusade turned Thibaut's thoughts to religion, and he announced his intention of singing henceforth only in honour of the Virgin Unfortunately his devotion took darker forms, for before sailing for the Holy Land he ordered and witnessed the burning of a hundred and eighty-three unfortunate men and women convicted of Manichaeism. The years 1239 and 1240 were spent in Palestine, and from the time of his return Thibaut devoted himself to efforts for the improvement of his dominions that won for him the title of *le Bon.* He died at Pampeluna on July 14, 1253

Thibaut was the most popular of all the 13th century song-writers, and his work is marked by a grace and sweetness which he owes perhaps in part to his association with the troubadours of the south. He is said to have set his own songs to music It seems doubtful whether the notes that have come down to us can with justice be attributed to him, but there is no contesting the musical quality of his verse His fame spread beyond the Alps, and Dante admired his poetry He was one of the most celebrated authors of *jeux-partis,* elaborate discussions between two interlocutors, usually on the subject of love

His works were edited in 1851 by P Tarbé in his *Chansonniers de Champagne.*

THIBAUT, ANTON FRIEDRICH JUSTUS (1774–1840), German jurist, was born at Hameln, in Hanover, on Jan 4, 1774, the son of an officer in the Hanoverian army He studied jurisprudence at Gottingen, Konigsberg and Kiel. Here in 1798 he was appointed extraordinary professor of civil law, and published his earlier works, including the important treatise (1799) *Theorie der logischen Auslegung des römischen Rechts* In 1802 Thibaut was called to Jena, where he wrote his chief work, *System des Pandektenrechts* (1803) This work is, in effect, a codification of the Roman law as it then obtained in Germany, modified by canon law and the practice of the courts into a comprehensive system of Pandect law In 1805 he went to Heidelberg, where he stayed till his death on March 29, 1840 His influence was great; and, except Gustav Hugo and Savigny, no civilian of his time was so well known. In 1814 appeared his *Civilistische Abhandlungen,* of which the principal was his famous essay advocating a national code for Germany This essay was inspired by the War of Liberation.

See Baumstark, *Thibaut, Blatter der Erinnerung* (1841), Karl Hagemann, *Aus dem Leben A F J Thibaut, mit Correspondenz,* in *die Preuss Jahrbucher* (1880), Teichmann, in *Holtzendorff's Rechtslexikon;* and E Landsberg, in *Allgemeine Deutsche Biographie,* vol 37.

THIBAW (now HSIPAW): *see* SHAN STATES

THIELMANN, JOHANN ADOLF, FREIHERR VON (1765–1824), Prussian cavalry soldier, was born at Dresden Entering the Saxon cavalry in 1782, he saw service against the French in the Revolutionary Wars and in the Jena campaign, and after Jena, at the siege of Danzig and at Friedland In 1809, as colonel of a Free-Corps, he opposed the advance of the Austrians into Saxony, and was promoted major-general, becoming lieutenant-general in 1810 As commander of the Saxon Heavy Cavalry Brigade he took part in the advance on Moscow (1812), and at Borodino attracted the attention of Napoleon, who took him into his own suite His own sovereign at the same time made him Freiherr In the war of Liberation Thielmann took a prominent part. When ordered to surrender the fortress of Torgan, of which he was governor, to the French, he resigned his command and joined the allies As a Russian general he reorganized the Saxon army after Leipzig, and in 1814 he commanded the Saxon corps operating in the Low Countries. Early in 1815 he became a lieutenant-general in the Prussian service, and in command of the 3rd army corps he took part in the Waterloo campaign, in which he fought the spirited action of Wavre (June 18–19) He was later a corps commander at Munster and at Coblenz, where he died in 1824

See von Petersdorf, *General Johann Adolf Freiherr von Thielmann* (Leipzig, 1894).

THIERRY, JACQUES NICOLAS AUGUSTIN (1795–1856), French historian, who was born at Blois on May 10, 1795 He was educated at the Blois Grammar School, and at the École normale supérieure. He embraced the ideas of the French Revolution with enthusiasm, and he became fired with Saint Simon's ideal society of the future. He became the secretary, and, as he would say himself, the "adopted son" of the famous visionary (1814–17); but, while most of Saint Simon's followers turned their attention to the affairs of life, devoting themselves to the problems, both theoretical and practical, of political economy, Thierry turned his to history. His imagination had been powerfully impressed by reading *Les Martyrs,* in which Châteaubriand had contrasted the two civilizations and the two races from which the modern world has sprung. His romantic ardour was later still further nourished by the works of

Sir Walter Scott, and though he did not himself actually write romances, his conception of history fully recognized the dramatic element. His main ideas on the Germanic invasions, the Norman Conquest, the formation of the communes, the gradual ascent of the nations towards free government and parliamentary institutions are already observable in the articles contributed by him to the *Censeur européen* (1817–20), and later in his *Lettres sur l'histoire de France* (1820). From Fauriel he learnt to use the original authorities, and by the aid of the Latin chronicles and the collection, as yet very ill understood, of the Anglo-Saxon laws, he composed his *Histoire de la Conquête de l'Angleterre par les Normands* (1825). This book, the preparation of which had required several years of hard work, cost Thierry his eyesight, in 1826 he was obliged to engage secretaries and in 1830 became quite blind Nevertheless he republished (1827) his *Lettres sur l'histoire de France,* with the addition of fifteen new ones, in which he described some of the more striking episodes in the history of the rise of the mediaeval communes

Thierry was ardent in his applause of the July Revolution and the triumph of liberal ideas He now re-edited, under the title of *Dix ans d'études historiques,* his first essays in the *Censeur européen* and the *Courrier français* (1834), and composed his *Récits des temps mérovingiens,* in which he reproduced in a vivid and dramatic form some of the most characteristic stories of Gregory of Tours These *Récits* appeared first in the *Revue des deux mondes;* when collected in volume form, they were preceded by long and interesting *Considérations sur l'histoire de France.* Thierry became a member of the Académie des Inscriptions et Belles Lettres, in 1841, on the motion of Villemain, the French Academy awarded him the first *Prix Gobert,* which became a kind of literary inheritance for him, being renewed in his favour fifteen years in succession. By the aid of zealous collaborators (including Bourquelot and Louandre) he compiled, in four volumes, a valuable *Recueil des monuments inédits de l'histoire du Tiers État* (1850–70), which, however, bear only on the northern part of France. He died in Paris on May 22, 1856

THIERS, LOUIS ADOLPHE (1797–1877), French statesman and historian, was born at Marseilles on April 16, 1797. He was educated, first at the lycée of Marseilles, and then in the faculty of law at Aix Here he began his lifelong friendship with Mignet, and was called to the bar. In 1821 Thiers went to Paris, and became a contributor to the *Constitutionnel.* Cotta, the well-known Stuttgart publisher, who was part-proprietor of the *Constitutionnel,* made over to Thiers a share of his dividends and he was thus relieved of any money anxiety.

Meanwhile Thiers became very well known in Liberal society, and he had begun the celebrated *Histoire de la révolution française* (10 vols, 1823–27), which founded his literary and helped his political fame. Coming as the book did just when the reaction against the revolution was about to turn into another reaction in its favour, it was assured of success In 1830 Thiers, with Armand Carrel, Mignet, and others started the *National,* a new opposition newspaper Thiers himself took a leading part in the actual revolution He ranked as one of the Radical supporters of the new dynasty At first Thiers, though elected deputy for Aix, obtained only subordinate places in the ministry of finance. After the overthrow of his patron Laffitte, he became much less radical, and, after the troubles of June 1832, was appointed to the ministry of the interior He repeatedly changed his portfolio, but remained in office for four years, became president of the council and in effect prime minister, and began his series of quarrels and jealousies with Guizot

At the time of his resignation in 1836 Thiers was foreign minister, and, as usual, wished for a spirited policy in Spain, which he could not carry out. He travelled in Italy for some time, and it was not till 1838 that he began a regular campaign of parliamentary opposition, which in March 1840 made him president of the council and foreign minister for the second time. But he held the position barely six months, and, being unable to force on the king an anti-English and anti-Turkish policy, resigned on Oct. 29 He now worked on his *Historie du Consulat et de l'Empire,* the first volume of which appeared in 1845. Though he was still a member of the chamber he spoke rarely, till after the beginning of 1846, when he was evidently bidding once more for power. When the revolution of February broke out he and Odilon Barrot were summoned by the king; but it was too late.

Under the republic he took up the position of conservative republican. The inconsistency of his conduct, especially in voting for Prince Louis Napoleon as president, was often and sharply criticized, one of the criticisms leading to a duel with a fellow-deputy, Bixio. He was arrested at the *coup d'état,* was sent to Mazas, and then escorted out of France. But in the following summer he was allowed to return. For the next decade his time was occupied for the most part on *The Consulate and the Empire.* It was not till 1863 that he re-entered political life, as deputy for a division of Paris. For the seven years following he was leader of the anti-Imperialists in the French chamber. While nominally protesting against its foreign enterprises, he perpetually harped on French loss of prestige, and so contributed more than any one to stir up the spirit which brought on the war of 1870

After the collapse of the empire Thiers visited in the autumn the different courts of Europe in the hope of obtaining some intervention, or at least some good offices. The mission failed; but the negotiator was immediately charged with another—that of obtaining, if possible, an armistice directly from Prince Bismarck Thiers was chosen deputy to the National Assembly by more than twenty constituencies (of which he preferred Paris), and was at once elected by the Assembly itself practically president, nominally *chef du pouvoir exécutif.* He lost no time in choosing a coalition cabinet, and then personally took up the hard task of negotiating peace. He succeeded in convincing the deputies that the peace was necessary, and it was (March 1, 1871) voted by more than five to one. Thiers held office for two years after the peace He had at first to meet and crush at once the Paris commune, and on Aug. 30 he became president of the republic.

His strong personal will and inflexible opinions had much to do with the resurrection of France, they also made it inevitable that he should excite violent opposition His talents and his temper made him utterly indisposed to maintain the attitude supposed to be incumbent on a republican president, and his tongue was never a carefully governed one. In January 1872 he formally tendered his resignation, and, though it was refused, almost all parties disliked him, while his chief supporters—men like Rémusat, Barthélemy Saint-Hilaire and Jules Simon—were men rather of the past than of the present In 1873 regulations were proposed, and on April 13, were carried, which were intended to restrict the executive and especially the parliamentary powers of the president The government was further weakened by a dissolution and reconstitution of the cabinet on May 19. Immediately afterwards the question was brought to a head by an interpellation moved by the duc de Broglie. The president declared that he should take this as a vote of want of confidence; a vote of this character (though on a different formal issue, and proposed by M. Ernoul) was carried by 16 votes in a house of 704. Thiers at once resigned (May 24). He died on Sept. 3, 1877.

His histories, in many different editions, and his speeches, as above, are easily accessible; his minor works and newspaper articles have not, we believe, been collected in any form Several years after his death appeared *Deux opuscules* (1891) and *Mélanges inédites* (1892), while *Notes et souvenirs,* 1870–73, were published in 1901 by "F. D.," his sister-in-law and constant companion, Mlle Félicie Dosne. Works on him, by M. Laya, M. de Mazade, his colleague and friend, M. Jules Simon, and others, are numerous. D Halévy, *Le Courrier de M. de Thiers* (1921), pp. 521; L. A. Thiers, *Thiers au pouvoir,* 1871–73 (1921), pp 357.

THIERS, a town of central France, capital of an arrondissement in the department of Puy-de-Dôme, 24 m. E.N.E. of Clermont-Ferrand, on the railway between that town and St. Étienne. Pop. (1926) 11,850. Thiers was sacked about 531 by the soldiers of Thierry, son of Clovis. About the same period Gregory of Tours speaks of a wooden chapel which may have occupied the site of the present church of Le Moutier. The streets rising in steep rows contain a number of 15th century houses. The church of St Genès was built in 575 by Avitus, bishop of Clermont, and rebuilt in the 12th century. It has some curious mosaic work of the Merovingian period and a fine tomb of the

13th century. The church of Le Moutier, formerly part of a Benedictine monastery, dates chiefly from the 11th century. Thiers is the seat of a sub-prefect and has a tribunal of commerce, a chamber of commerce and a board of trade arbitrators Its special industry is the manufacture of cutlery.

THIETMAR (DIETMAR or DITHMAR) OF MERSEBURG (975–1018), German chronicler, was a son of Siegfried, count of Walbeck, and was related to the family of the emperor Otto the Great. Born on July 25, 975, he was educated at Quedlinburg and at Magdeburg and became provost of Walbeck in 1002 and bishop of Merseburg seven years later. He took some part in the political events of the time, in 994 he was a hostage in the hands of the Northmen He died on Dec 1, 1018.

Thietmar wrote a *Chronicon* in eight books, which deals with the period between 908 and 1018. For the earlier part he used Widukind's *Res gestae Saxonicae*, the *Annales Quedlinburgenses* and other sources, the latter part is the result of personal knowledge. It has been edited by J M Lappenberg in Band III. of the *Monumenta Germaniae historica, Scriptores;* and by F. Kurze (Hanover, 1889); and has been translated into German by J. Laurent (new ed revised by W Wattenbach, Leipzig, 1892). *See* F Kurze, *Bischof Thietmar von Merseburg und seine Chronik* (Halle, 1890); and W. Wattenbach, *Deutschlands Geschichtsquellen*, Band II. (Berlin, 1904)

THIONVILLE, capital of the arrondissements of Thionville-Est and Thionville-Ouest in the department of Moselle, France, 22 m N from Metz by rail. Pop (1926), 11,974 Its German name is Diedenhofen It is an ancient Frank town (Theudonevilla, Totonisvilla), in which imperial diets were held in the 8th century, was captured by Condé in 1643 and fortified by Vauban, capitulated to the Prussians, after a severe bombardment, on Nov. 25, 1870, and was returned to France in 1918.

THIOPHEN, an organic sulphur compound present in small quantities in coal-tar benzene, from which it is separated only with considerable difficulty, owing to the close similarity of the physical and chemical properties of the two substances Thiophen is a colourless liquid with the odour of benzene, the former boils at 84° C, the latter at 80 5° C. Both readily undergo bromination, nitration and sulphonation Coal-tar toluene is similarly accompanied by small amounts of α- and β-methylthiophens (thiotolens) and the xylenes contain traces of dimethylthiophens (thioxens) In each case the sulphur compound simulates closely the boiling point and other properties of the hydrocarbon Hence in their relationship to the coal-tar hydrocarbons, thiophen and its homologues constitute a remarkable case of chemical "protective mimicry"

(I.) 
 (II.)

Thiophen (formula I) was first recognised in coal-tar benzene and isolated therefrom by V. Meyer (1883), who availed himself of the fact that thiophen is more readily sulphonated than benzene at the ordinary temperature Benzene containing thiophen was shaken with cold, concentrated sulphuric acid, the impure thiophensulphonic acid converted into lead salt and the latter distilled with ammonium chloride Impure thiophen was thus obtained and the process was repeated until the product after rectification was pure An alternative isolation due to O. Dimroth (1899) consists in boiling the benzene–thiophen mixture with mercuric acetate; a mercury derivative of thiophen which separates is decomposed by hydrochloric acid, regenerating pure thiophen

Thiophen is obtainable (1) by passing ethyl sulphide through a red hot tube, or (2) by heating succinic anhydride, succindialdehyde or metallic succinates with sulphides of phosphorus It is readily recognized by the intense blue coloration developed when a trace of thiophen or coal-tar benzene is added to isatin in concentrated sulphuric acid (the indophenin reaction).

The 1.4-diketones react in their dienolic forms on heating with phosphorus pentasulphide and yield homologues of thiophen 2:5-dimethylthiophen (formula II) is thus obtained from acetonylacetone, $CH_3{\cdot}C(OH){:}CH{\cdot}CH{:}C(OH){\cdot}CH_3$. *See* V. Meyer, *Der Thiophengruppe*, 1888.

THIRD DEGREE, originally an American slang or cant term, but now in common use in the United States and coming into such use in Great Britain, to designate the employment of brutal methods by police or prosecuting authorities to extort information or confessions from persons in custody. The phrase is believed to have been suggested by the third masonic degree, that of master mason, which is conferred with considerable ceremony

The phrase as often employed includes not only the use of physical violence, but also such forms of torture as depriving a prisoner of food, drink, sleep and toilet facilities and the prolonged and uninterrupted interrogation of him when exhausted, suffering and broken down by such deprivations. It is more commonly applied however to those forms of physical assault (such as beating with a rubber hose) which produce pain but leave no traces.

Since admissions and confessions of guilt have great probative weight when made voluntarily, it is obvious that unscrupulous officials interested in procuring convictions may be tempted to force unwilling confessions by improper means, and falsely to represent such confessions as voluntary In several of the United States, assertions that such methods are used to extort confessions or to elicit information have for some time been so common as seriously to disturb the courts Similar charges have in a few cases been made recently in the course of criminal trials in England

It is impossible to state to what extent the practices described prevail, as obviously there is no way in which the truth of an assertion that they have been employed can be determined with certainty since those charged with employing them invariably make denial and the facts are known only to the participants But those who are in close touch with the administration of the criminal law in many of the larger American cities do know that juries frequently render verdicts of acquittal in cases where alleged confessions, claimed by defendants to have been evoked by the use of force, have been received in evidence, which verdicts are explicable on no other theory than that the jury regarded the circumstances with suspicion and wholly rejected the alleged confession on that ground (C A P.)

THIRLWALL, CONNOP (1797–1875), English bishop and historian, was born at Stepney, London, on Jan 11, 1797 He was educated at Charterhouse and at Trinity college, Cambridge In October 1818 he was elected to a fellowship, and went for a year's travel on the Continent On his return he settled down to study law, but without much zeal, and in 1827 he definitely abandoned law, and was ordained deacon At Rome in 1819 he had fallen in with Bunsen, and since that time had been interested in German literature He now joined with Hare in translating Niebuhr's *History of Rome* (1828) On Hare's departure from Cambridge in 1832, Thirlwall became assistant college tutor and was involved in the controversy upon the admission of Dissenters which arose in 1834 Thirlwall, in replying to objections by Thomas Turton, pointed out that no provision for theological instruction was in fact made by the colleges except compulsory attendance at chapel, and that this was mischievous After this outburst he had to resign his position as assistant-tutor Nevertheless he received from Lord Brougham the living of Kirby-under-Dale in Yorkshire Then he began his *History of Greece* (1835–44), which has remained a standard work

In 1840 Thirlwall was raised by Lord Melbourne to the see of St David's The great monument of his episcopate is the eleven famous charges in which he from time to time reviewed the position of the English Church with reference to pressing questions of the day—addresses at once judicial and statesmanlike, full of charitable wisdom and massive sense Thirlwall was one of the four prelates who refused to inhibit Bishop Colenso from preaching in their dioceses, and the only one who withheld his signature from the addresses calling upon Colenso to resign his see He took the liberal side in the questions of Maynooth,

of the admission of Jews to parliament, of the Gorham case, and of the educational conscience clause He was the only bishop who voted for the disestablishment of the Irish Church.

During his latter years Thirlwall took great interest in the revision of the Authorized Version of the Bible, and was chairman of the revisers of the Old Testament. He resigned his see in May 1874, and retired to Bath, where he died on July 27, 1875. He lies in Westminster Abbey in the same grave as Grote.

Thirlwall's *History of Greece* (new ed 1845–52) remains a standard book. *See* his *Remains, Literary and Theological,* ed J. J. S Perowne in three volumes (1877–80), two of which are occupied by his charges, *Letters, Literary and Theological,* with a connecting memoir, ed J J S Perowne and L Stokes (1881), and *Letters to a Friend* (Miss Johnes of Dolaucothy), ed Dean Stanley (1881). They were originally published by Dean Stanley, and there is a revised and corrected edition For a general view of Thirlwall's life and character, *see* the *Edinburgh Review,* vol cxlii.; for a picture of him in his diocese, *Temple Bar,* vol lxxvi.

THIRSK, a town and parish in the North Riding of Yorkshire, England, 22 m. N.W. by N. of York, on the L N.E. railway, on the Cod Beck, a tributary of the river Swale on the edge of the Vale of York The district is known as the Vale of Mowbray. Pop. (1921) 2,755 Thirsk is first mentioned as a borough in a charter granted by Roger de Mowbray to Newburgh priory in the reign of Henry II. The Perpendicular church of St Mary with its 80 ft tower, is one of the most beautiful churches in the Riding.

THIRST: *see* Hunger and Thirst

THIRTY YEARS' WAR (1618–1648), the general name of a series of wars in Germany which began formally with the claim of Frederick, the elector palatine, to the throne of Bohemia and ended with the treaty of Westphalia It was primarily a religious war and was waged with the bitterness characteristic of such wars, but at the same time political quarrels were interwoven with the religious question: with the consequence that the armies, considering themselves as their masters' retainers rather than champions of a cause, plundered and burned everywhere, military violence being in no way restrained by expediency.

Formation of the "Union" and the "League."—Fifty years before the outbreak of the war the Convention of Passau had compromised the burning questions of the Reformation, but had left other equally important points as to the secularization of church lands and the consecration of Protestant bishops to the future Each such case, then, came before the normal government machine—a Diet so constituted that even though at least half of the secular princes and nine-tenths of their subjects were Protestants, the voting majority was Catholic Moreover, the Jesuits had rallied and disciplined the forces of Catholicism, while Protestantism, however firm its hold on the peoples, had dissipated itself in doctrinal wrangles. The strongest side was that which represented conservatism, peace and Catholicism Realizing this from the preliminary mutterings of the storm, the Protestant princes formed a "Union," which was promptly answered by the Catholic League. This group was headed by the wise and able Maximilian of Bavaria and supported by his army, which he placed under a soldier of long experience and conspicuous ability, Count Tilly

The Bohemian Movement.—The war arose in Bohemia, where the Protestant magnates refused to elect Ferdinand of Austria to the vacant throne, offering it instead to Frederick, the elector palatine. But the aggrandizement of this elector's power was entirely unacceptable to most of the Protestant princes—to John George of Saxony above all. They declared themselves neutral, and Frederick found himself an isolated rebel against the Emperor Ferdinand.

Even thus early the struggle showed itself in the double aspect of a religious and a political war. Just as the Bohemians and their nominee found themselves looked upon askance by the other Protestants, so the emperor himself was unable to call upon Maximilian's Army of the League without promising to aggrandize Bavaria. Only the incoherence of the rebels saved Ferdinand. They ordered taxes and levies of soldiers, but the taxes were not collected, and the soldiers, unpaid and unfed, plundered the country-side The only coherent force was the mercenary corps of Ernst von Mansfeld, which, thrown out of employment by the termination of a war in Italy, had entered the service of Frederick. Nevertheless, the Bohemians were conspicuously successful at the outset: they won several engagements, and appeared before Vienna itself Moravia and Silesia supported the Bohemians, and the Austrian nobles attempted, in a stormy conference, to wrest from Ferdinand not only religious liberty but also political rights that would have made Austria and Bohemia a loose confederation of powerful nobles Ferdinand firmly refused, though the deputation threatened him to his face, and the tide ebbed as rapidly as it had flowed No sooner had Frederick accepted the crown than Maximilian let loose the Army of the League. Spanish aid arrived Spinola with 20,000 men from the Low Countries and Franche Comté invaded the Palatinate, and Tilly, with a combined army of Austrians and Bavarians crushed the Bohemians at the battle of the Weisser Berg near Prague (Nov 8–18, 1620) With this the Bohemian war ended Some of the nobles were executed, and Frederick, the "Winter King," was put to the ban of the empire. But the emperor's revenge alarmed the Union princes They were Protestants, and neither in religion nor in politics could they suffer an all-powerful Catholic emperor Moreover, the alternative to a powerful emperor was a powerful Bavaria, and this they liked almost as little

Predatory Armies.—There still remained for the army of Tilly the reduction of the smaller garrisons in Bohemia, which when finally expelled rallied under Mansfeld, the last general of a lost cause Then there began the wolf-strategy that was the distinguishing mark of the Thirty Years' War An army even of ruffians could be controlled, as Tilly controlled that of the League, if it were paid But Mansfeld, the servant of a shadow king, could not pay. Therefore "he must of necessity plunder where he was His movements would be governed neither by political nor by military considerations. As soon as his men had eaten up one part of the country they must go on to another." These movements were for preference made upon hostile territory, and Mansfeld was so far successful in them that the situation in 1621 became distinctly unfavourable to the emperor. Tilly and the League Army fought warily and did not risk a decision Thus even the proffered English mediation in the German war might have been accepted but for the fact that in the Lower Palatinate a corps of English volunteers, raised by Sir Horace Vere for the service of the English princess Elizabeth, the fair queen of Bohemia, found itself compelled, for want of pay and rations, to live, as Mansfeld lived, on the country along the Rhine. This brought about a fresh intervention of Spinola's Spaniards who had been destined to the interminable Dutch war Moreover Mansfeld, having thoroughly eaten up the Palatinate, decamped into Alsace, where he seized Hagenau and wintered in safety

The winter of 1621–22 passed in a series of negotiations which failed because too many interests, inside and outside Germany, were bound up with Protestantism to allow the Catholics to speak as conquerors, and because the cause of Protestantism was too much involved with the cause of the elector palatine to be taken in hand with energy by all Protestant princes. But Frederick and Mansfeld found two allies One was Christian of Brunswick, the gallant young knight-errant, titular bishop of Halberstadt, queen Elizabeth's champion, and withal, though he called himself *Gottes Freund, der Pfaffen Feind,* a plunderer of peasants as well as of priests The other was the margrave George Frederick of Baden-Durlach, reputed to be of all German princes the most skilful sequestrator of ecclesiastical lands In April 1622, while Vere garrisoned the central fortresses of the Palatinate, Mansfeld, Christian and George Frederick took the field against Tilly, who at once demanded assistance from Spinola. The latter, though engaged with the Dutch, sent a corps under his subordinate Cordova. Mansfeld and the margrave of Baden defeated Tilly at Wiesloch (April 17–27, 1622). But soon the allies had to separate to find food. Then Cordova came up, and Tilly and the Spaniards combined defeated George Frederick at Wimpfen on the Neckar (April 26–May 6). Cordova chased Mansfeld back into Alsace, while Tilly went north to oppose Christian of Brunswick on the

Main. On June 10–20 the latter's army was almost destroyed by the League Army at Höchst. Mansfeld, and with him Frederick, had already set out from Alsace to join Christian, but when that leader arrived with only a handful of beaten men, the war was practically at an end Frederick took Mansfeld and Christian back to Alsace, and after dismissing their troops, retired to Sedan. Henceforth he was a picturesque but powerless exile, and his lands and his electoral dignity, forfeited by the ban, went to the prudent Maximilian, who was created by the Emperor elector of Bavaria.

Mansfeld and Christian of Brunswick.—The next act in the drama, however, had already begun with the adventures of the outlaw army of Mansfeld and Christian. After Höchst, had it not been for them, the war might have ended in compromise. James I of England was busy as always with mediation schemes. Spain, being then in close connection with him, and the Protestant princes of North Germany being neutral, a diplomatic struggle over the fate of the Palatinate might have ended in a new convention of Passau that would have regulated the present troubles and left the future to settle its own problems. The struggle would only have been deferred, it is true, but meanwhile the North German Protestants remained powerless and inactive, while Tilly's army was kept in hand to deal with the adventurers.

These, after eating up Alsace, moved on to Lorraine, whereupon the French Government "warned them off." But ere long they found a new employment. The Dutch were losing ground before Spinola, who was besieging Bergen-op-Zoom, and the States-General invited Mansfeld to relieve it. The adventurers moved straight across Luxemburg and the Spanish Netherlands to the rescue Cordova barred the route at Fleurus near the Sambre, but the desperate invaders, held together by the sheer force of character of their leaders, thrust him out of their way (Aug. 19–29, 1622) and relieved Bergen-op-Zoom. But ere long, finding Dutch discipline intolerable, they marched off to the rich country of East Friesland

Their presence raised fresh anxieties for the neutral princes of North Germany In 1623 Mansfeld issued from his Frisian stronghold, and the threat of a visitation from his army induced many princes of the Lower Saxon Circle to join him Christian was himself a member of the Circle, and although he resigned his bishopric, he was taken, with many of his men, into the service of his brother, the duke of Brunswick-Wolfenbuttel Around the mercenary nucleus gathered many thousands of volunteers, for the towns and the nobles' castles alike were alarmed at the progress of the Catholics, who were reclaiming Protestant bishoprics But this movement was nipped in the bud by the misconduct of the mercenaries The authorities of the Circle ordered Christian to depart. He returned to Holland, therefore, but Tilly started in pursuit and caught him at Stadtlohn, where on July 28–Aug. 6, 1623 his army was almost destroyed Thereupon the Lower Saxon Circle, which, like the Bohemians, had ordered collectively taxes and levies of troops that the members individually furnished either not at all or unwillingly, disbanded their army to prevent brigandage. Mansfeld, too, having eaten up East Friesland, returned to Holland in 1624.

Foreign Intervention.—The only material factor was now Tilly's ever-victorious Army of the League, but for the present it was suspended inactive in the midst of a spider's web of European and German diplomacy. Spain and England had quarrelled. The latter became the ally of France, over whose policy Richelieu now ruled, and the United Provinces and (later) Denmark joined them. Thus the war was extended beyond the borders of the empire, and the way opened for ceaseless foreign interventions. From the battle of Stadtlohn to the pitiful end 20 years later, the decision of German quarrels lay in the hands of foreign powers. France was concerned chiefly with Spain, whose military possessions all along her frontier suggested that a new Austrasia, more powerful than Charles the Bold's, might arise James, in concert with France, re-equipped Mansfeld and allowed him to raise an army in England, but Richelieu was unwilling to allow Mansfeld's men to traverse France, and they ultimately went to the Low Countries, where, being raw pressed-men for the most part, and having neither pay (James having been afraid to summon parliament) nor experience in plundering, they perished in the winter of 1625 At the same time a Huguenot rising paralysed Richelieu's foreign policy. Holland after the collapse of Mansfeld's expedition was anxious for her own safety owing to the steady advance of Spinola. The only member of the alliance who intervened in Germany itself was Christian IV. of Denmark, who as duke of Holstein was a member of the Lower Saxon Circle, and as king of Denmark was anxious to extend his influence over the North sea ports. Gustavus Adolphus of Sweden, judging better than any the difficulties of affronting the empire and Spain, contented himself with carrying on a war with Poland

Intervention of Christian of Denmark.—Christian IV. raised an army in his own lands and in the Lower Saxon Circle in the spring of 1625. Tilly at once advanced to meet him. But he had only the Army of the League, the Emperor's troops being occupied in a war on Gabriel Bethlen of Transylvania. Then, like a *deus ex machina*, Wallenstein, duke of Friedland, came forward and offered to raise and maintain an army in the emperor's service. It was an army like Mansfeld's in that it lived on the country, but its exactions were systematic and the products economically used, so that it was possible to feed 50,000 men instead of 20,000. This method, the high wages which he paid, and his own princely habits and commanding personality gave it a cohesion that neither a free company nor an army of mere Lower Saxon contingents could ever hope to attain.

In 1625, Wallenstein kept his new army well away from the risks of battle until he could trust it to conquer It was fortunate for Ferdinand that he did so. Christian IV, who had been joined by Mansfeld and Christian of Brunswick, had, in 1626, 60,000 men. Wallenstein and Tilly together had only a very slight numerical superiority, and behind them was nothing Even the hereditary provinces of Austria were threatening revolt and Gabriel Bethlen was again giving trouble. But on the other side the English subsidies failed, and the Protestant armies soon began to suffer in consequence. Tilly opposed Christian IV, Wallenstein, Mansfeld The latter advanced upon Wallenstein, attacked him in an entrenched position at the Bridge of Dessau and was thoroughly defeated (April 15–25, 1626). He then wandered across Germany into Silesia and joined Bethlen. Wallenstein followed up, and by taking up strong positions, compelled Mansfeld and Bethlen to choose between attacking him and starving So, without a battle, he brought about a truce, whereby Bethlen was disarmed and Mansfeld was required to leave Hungary Mansfeld and Christian of Brunswick died soon afterwards, the one in Hungary, the other in Westphalia. King Christian, left alone and unable without English subsidies to carry on the war methodically, took the offensive, as Mansfeld had done, in order to live on the Thuringian countryside. But Tilly, with whom Wallenstein had left a part of his army, moved as quickly as the king, brought him to action at Lutter-am-Barenberge in Brunswick and totally defeated him (Aug 17–27)

With this, armed opposition to Tilly and Wallenstein in the field practically ceased, but their armies continued to live on the country. Christian of Denmark slowly gave up fortress after fortress to Tilly. Wallenstein, returning from the campaign against Gabriel Bethlen, drove Christian's army through Jutland and into the sea (1627). But Wallenstein, with his dreams of a united Germany free in conscience and absolutely obedient to the emperor, drifted farther and farther away from the League Ferdinand thought that he could fulfil the secular portion of Wallenstein's policy while giving satisfaction to the Catholics. The princes and bishops of the League continued to oppose any aggrandizement of the emperor's power at their expense and to insist upon the resumption of church lands. In this equilibrium the North German Protestant cities were strong enough to refuse to admit Wallenstein's garrisons. In 1628 Wallenstein, who had received the duchy of Mecklenburg on its rightful lord being put to the ban for his share in the Danish war, began to occupy his new towns, and also to spread along the coasts But the Hanse towns rejected his overtures, and Stralsund, second-rate seaport though it was, absolutely refused to admit a garrison of his wild soldiery The result was the famous siege of Stralsund (Feb. to Aug. 1628), in which the

citizens compelled the hitherto unconquered Wallenstein army to retire. The siege was, as the result proved, a turning-point in German history. The emperor's policy of restoring order had practically universal support. But the instrument of the restoration was a plundering army. Even this might have been borne had Wallenstein been able to give Germany, as he wished, not only peace but religious freedom. When the Edict of Restitution (1629) gave back 150 northern ecclesiastical foundations to the Catholics, men were convinced that one ruler meant one religion.

Gustavus Adolphus of Sweden.—Rather than endure this the North Germans called in Gustavus Adolphus of Sweden and, just as Gustavus landed, the resentment of the princes of the League against Wallenstein's policy and Wallenstein's soldiers came to a head, and the emperor was forced to dismiss him. His soldiers were taken over by Tilly, and for the moment he disappeared from the scene On Gustavus's side, a thoroughly trained army, recruited from good yeomen and stout soldiers of fortune, paid good wages, and led by a great captain, was a novelty in war that more than compensated for Tilly's numerical superiority. Gustavus, however, after landing at Peenemunde in June, spent the rest of the year in establishing himself firmly in Mecklenburg and Pomerania, in order to secure the active support of the more important Protestant princes, so as to appear as an auxiliary rather than a principal in the German conflict First the old duke Bogislav of Pomerania, then George William of Brandenburg joined him, very unwillingly He was soon afterwards allied with France, by the treaty of Bärwalde (Jan 1631) John George of Saxony, still attempting to stifle the war by a policy of neutrality, sent a last appeal to Vienna, praying for the revocation of the Edict of Restitution. Meanwhile Tilly had marched into north-eastern Germany, where his lieutenant Pappenheim was besieging Magdeburg. This city had twice defied Wallenstein's attempts to introduce a garrison, and it was now in arms against the League Gustavus, as yet without active allies, thought it impossible to go forward alone, and could only hope that his sudden and brilliant storm (April 3–13) of Frankfurt-on-Oder would distract Tilly from the siege.

Sack of Magdeburg.—But the hope was vain and when, realizing this, he moved directly to Magdeburg's relief, his passage through the territories of the Electors of Brandenburg and Saxony was delayed by the objections of the Protestant princes While he was negotiating with them in turn, Magdeburg, although the citizens fought desperately, was stormed, sacked and burned on the night of May 10, 1631, amidst horrors that neither of the imperialist generals was able to check. The Catholics rejoiced as though for another St. Bartholomew's day, the Protestants were paralysed, and Gustavus, accused on all hands of having allowed the Magdeburgers to perish, sorrowfully withdrew into Pomerania But Tilly, in spite of Pappenheim's remonstrances, turned westward against Hesse-Cassel and other minor principalities whose rulers had declared for Gustavus. The king of Sweden, thereupon, advanced to Werben (at the junction of the Elbe and the Havel), where his army entrenched itself, and, in spite of sickness and famine, stoically awaited the attack The desired result was achieved At the end of July Tilly, returning from the west, made his appearance and was twice repulsed (July 13–23 and 18–28), losing 6,000 men out of 22,000 Thereupon, turning away from Gustavus's entrenchments, Tilly invaded Saxony, being reinforced *en route* by 20,000 men from Italy The elector John George at once made an alliance with the Swedes.

Battle of Breitenfeld.—Then Gustavus advanced in earnest. He crossed the Elbe at Wittenberg. 16,000 Saxons joined his 26,000 Swedes at Duben, and some of the western Germans had already come in. Tilly had just captured Leipzig, and outside that place, carried away by Pappenheim's enthusiasm, he gave battle on Sept. 7–17 to the now superior allies. The first battle of Breitenfeld (*q.v.*) was a triumphant success for Gustavus and for the new Swedish system of war Though the raw Saxons were routed at the outset by Tilly's men, the Swedes on the other wing drove the veterans of the League off the field in disorder, leaving 6,000 dead. Tilly himself was thrice wounded and barely escaped

All Protestant Germany hailed Gustavus as the liberator. John George, the Swedish general Horn and the Swedish chancellor Oxenstierna united in advising Gustavus to march straight upon Vienna. Richelieu was of the same mind. But Gustavus deliberately chose to move into South Germany, there to organize the cities and the princes in a new and stronger Protestant Union, the *Corpus Evangelicorum*, and to place himself in a country full of resources whence he could strike out against the emperor, Tilly and the Rhine Spaniards in turn. The Swedish army pushed on to Mainz, where it wintered in luxury. The Palatinate was reorganized under Swedish officials and the reformed religion established again. In March 1632 the campaign was resumed. Nuremberg and Donauwörth welcomed Gustavus. Tilly's army, reorganized for the defence of Bavaria, stood to fight on the Lech, but the passage was forced (April 4–14) and Tilly himself was mortally wounded Augsburg, Munich and all the country south of the Danube were occupied without resistance. At the same time John George's Saxons, advancing into Bohemia, entered Prague without firing a shot.

Wallenstein Returns.—The emperor had now either to submit or to reinstate Wallenstein Wallenstein demanded as the price of his services the reversal of the Edict, and power to dethrone every prince who adhered to the Swedes His terms were accepted, and in April 1632 he took the field as the emperor's *alter ego* with a new army that his recruiters had gathered in a few weeks He soon expelled the Saxons from Bohemia and offered John George amnesty and the rescinding of the Edict as the basis of peace. The elector, bound by his alliance with Gustavus, informed the Swedish king of this offer, and a series of negotiations began between the three leaders But John George had too much in common with each to follow either Wallenstein or Gustavus unreservedly, and the war recommenced. The Swedish king had now to meet Wallenstein's new army of 60,000, composed of the men immortalized by Schiller's play, excellent in war and in plundering, destitute of all home and national ties, and owning allegiance to its general alone While Gustavus in Franconia was endeavouring with little success to consolidate his *Corpus Evangelicorum* Wallenstein came upon the scene Gustavus offered him battle But as in 1625 Wallenstein would risk no battle until his army had gained confidence. He entrenched himself near Furth, while Gustavus camped his army about Nuremberg and a contest of endurance ensued Wallenstein, aided by his superiority in irregular cavalry, was able to starve for three days longer than the king, and at last Gustavus furiously attacked the entrenchments (battle of the Alte Veste, Aug. 24–Sept. 3, 1632) and was repulsed with heavy losses Thereupon he retired, endeavouring in vain to tempt Wallenstein out of his stronghold by making his retreat openly and within striking distance of the imperialists. Wallenstein had other views than simple military success. Instead of following Gustavus he marched into Saxony, his army plundering and burning even more thoroughly than usual in order to force the Saxons into peace. Gustavus followed with the swiftness that was peculiar to the Swedish system, and concentrated at Erfurt when Wallenstein had scarcely mastered Leipzig But it was now late in the season, and Wallenstein hoped to spin out the few remaining weeks of the campaign in an entrenched position. Gustavus, without waiting for Arnim's Saxons to join him, suddenly moved forward, and on Nov. 6–16 the battle of Lutzen (*q v*) was fought, a battle as fierce even as Breitenfeld. Gustavus was slain, but Wallenstein's army was driven from the field.

The League of Heilbronn.—The fall of Gustavus practically determined the intervention of France, for Richelieu supported all electors, Catholic or Protestant, against the central power at Vienna as part of his anti-Spanish policy, and French assistance was now indispensable to the Protestants. For although Lützen was a victory and the Protestant circles formed the League of Heilbronn in April 1633, the emperor was really in the ascendant. John George of Saxony needed but little inducement to make peace. But the tragedy of Lützen was soon to be followed by the tragedy of Eger. Wallenstein, gradually forming the resolve of forcing peace on Germany with his army, relaxed his pressure on Saxony, and flung himself upon the Swedish garrisons in Silesia.

Winning a victory at Steinau (Oct. 11, 1633) and capturing one town after another, he penetrated almost to the Baltic. But he was recalled to the south-west before his operations had had any effect. The Swedish army, now under Bernhard of Saxe-Weimar, Horn and Banér, had returned to the South, and took Regensburg from Maximilian's army. But it was now late in the year and Wallenstein was intent upon peace. With this object he endeavoured to secure the higher officers of the army, but these were gradually won over by Spanish emissaries; the emperor, having decided to continue the war in alliance with Spain, dismissed his general for the second time. Wallenstein then openly attempted to unite the Swedish, Saxon and other Protestant armies with his own, so as to compel all parties to make peace. But his officers would not follow, the *coup d'état* failed, and Wallenstein was murdered at Eger by his own lieutenants, with the full sanction of the Emperor (Feb 15–25, 1634).

All idea of German unity died with him, and for the next 14 years Germany was simply the battle-ground of French, Spanish, Austrian and Swedish armies, which, having learned the impunity and advantages of plunder in the school of Mansfeld and Wallenstein, reduced the country to a state of misery that no historian has been able to describe, save by detailing the horrors of one or other village among the thousands that were ruined Germany remained for a century in the stillness of exhaustion

Battle of Nordlingen.—Success was for the present with the emperor and Spain Under the leadership nominally of the king of Hungary, Ferdinand's heir, but really of Gallas, the army recaptured Regensburg and Donauworth, and when the Spanish Cardinal Infante joined them with 15,000 men on his way from Italy to the Netherlands, they were invincible. Bernhard of Weimar and the Swedes attacked them in an entrenched position at Nordlingen (Aug 27/Sept. 6, 1634) and was beaten with absolutely ruinous loss. The model army of Gustavus perished there, and for the rest of the war a Swedish army, except for some advantages of organization and technical form, was intrinsically no better than another John George, having obtained from Ferdinand a compromise on the question of the Edict, agreed to the peace of Prague (May 20–30, 1635), wherein all that was Protestant in 1627 was to remain so, or if since resumed by the Roman Church to be returned to the Lutherans. A certain number of princes followed John George's example on the same terms. There was now no ideal, no objective, common even to two or three parties. Gustavus's *Corpus Evangelicorum* as a German institution was moribund since Nordlingen, and Richelieu and the Spaniards stepped forward as the protagonists

The Policy of Richelieu.—The centre of gravity was now the Rhine valley, the highroad between Spanish Italy and the Spanish Netherlands. Richelieu had, as the price of his assistance after Nördlingen, taken over the Alsatian fortresses held by the Swedes, and in May, just before the treaty of Prague was signed, he declared war on Spain. The French army numbered 130,000 men in 1635, and 200,000 in the year after. One army assembled in Upper Alsace for the attack of the Spaniards in Franche Comté; another occupied Lorraine, which had been conquered in 1633; a corps under Henri de Rohan was despatched from the same quarter across Switzerland, to expel the enemy from the Valtelline, Another force, co-operating with the duke of Savoy, was to attack the Milanese. Bernhard was to operate in the Rhine and Main country. Having thus arranged to isolate the Spanish Netherlands, Richelieu sent his main army, about 30,000 strong, thither to join Frederick Henry of Orange and so to crush the Cardinal Infante. This was strategy on a scale hitherto unknown in the war. Richelieu had unified France under the single authority of the king, and his strategy, like his policy, was masterful and clear. But the event proved that his scheme was too comprehensive. Richelieu proposed to strike at each of the two halves of his enemy's power at the same time as he separated them. His forces were not sufficient for these tasks and he was therefore compelled to eke them out, both in Italy and the Netherlands, by working with allies whose interests were not his. Popular outbreaks among the Brabanters and Flemings led Frederick Henry to withdraw to his own country, and in 1636 the French northern army had to face the whole of the Cardinal Infante's forces. In Italy the Franco-Piedmontese army achieved practically nothing In Alsace and Lorraine neither side was strong enough to prevail Bernhard waged a desultory campaign in Germany, and later, when supplies gave out he and his army were taken into the French service In eastern Germany the consequences of the peace of Prague were that Saxony, Brandenburg and other States, signatories to the treaty, were *ipso facto* the enemies of those who continued the war. Thus John George turned his arms against the Swedes in his neighbourhood But their commander Banér was as superior in generalship as he was inferior in numbers, and held the field until a truce between Sweden and Poland set free a fresh Swedish corps that had been held ready for eventualities in that country. This corps, under Torstensson, joined Banér in October, and on Nov. 1 they won an action at Domitz on the Elbe

Thus Richelieu's great scheme was only very partially executed The only important military events of the year took place outside Germany, within Germany men were chiefly occupied in considering whether to accept the terms of the peace of Prague But the land had no rest, for the armies were not disbanded. In 1636 the movements foreshadowed in 1635 were carried out with energy. John George, aided by an imperialist army, threatened to interpose between Banér and the Baltic. But Banér was too quick for them. Before the Brandenburg contingent could join John George, he brought on a general action at Wittstock (Sept 24–Oct 4, 1636) The elector had 30,000 men against 22,000 and sought to attack both in front and rear But while his entrenchments defied the frontal attack Banér threw most of his army upon the enveloping force and crushed it. The Swedes lost 5,000 killed and wounded, the combined army 11,000 killed and wounded and 8,000 prisoners The prestige of so brilliant a victory repaired even Nordlingen, and many North German princes who were about to make peace took fresh heart

Invasion of France.—In the west, though there were no such battles as Wittstock, the campaign of 1636 was one of the most remarkable of the whole war The Cardinal Infante was not only relieved by the retreat of the Dutch, but also reinforced by a fresh army[1] under a famous cavalry officer, Johann von Weert He prepared, therefore, to invade France from the north-west The French were too much scattered to offer an effective resistance, and the Cardinal Infante's generals took Corbie, passed the Somme and advanced on Compiègne For a moment Paris was terror-stricken, but the Cardinal Infante missed his opportunity. Louis XIII and Richelieu turned the Parisians from panic to enthusiasm The burghers armed and drilled, money, too, was willingly given, and some 12,000 volunteers went to Compiègne, where all levies and reinforcements were concentrated Thus the army at Compiègne was soon 50,000 strong. It was only half mobile owing to its rawness and its "trained-band" character, but the Spaniards and Bavarians retired unmolested to oppose Frederick Henry in the Low Countries

During the episode before Compiègne another storm burst on the eastern frontier of France. This was the inroad into Burgundy of Gallas with the main imperialist army He took a few small towns, but Dijon and the entrenchments of Bernhard's army there defied him, and his offensive dwindled down to an attempt, soon abandoned, to establish his army in winter quarters in Burgundy.

War in Italy.—In Italy the duke of Savoy with his own army and a French corps under Créqui advanced to the Ticino, and an action in which both sides lost several thousand men was fought at Tornavento, a few miles from the future battlefield of Magenta, to which in its details this affair bears a singular resemblance (June 22, 1636). But the victory of the French was nullified by the refusal of Victor Amadeus, for political reasons, to advance on Milan.

The campaign of 1637, on the French and Spanish side, was not productive of any marked advantage to either party. From Catalonia a Spanish army invaded Languedoc, but was brought to a standstill in front of the rocky fortress of Leucate and defeated with heavy losses by the French relieving army under Schom-

[1] Composed partly of Bavarians, partly of Cologne troops.

berg On the Low Countries frontier the cardinal de La Valette captured Câteau Cambrésis, Landrecies and Maubeuge.

War on the Rhine.—On the Rhine and in the adjacent countries Johann von Weert, returning from Belgium with his Bavarians, captured Ehrenbreitstein, the citadel of Coblenz, and expelled small French detachments from the electorate of Trier, whose ruler, the archbishop, had been put to the ban by the emperor. Then, passing into the Main valley, he took Hanau. The main imperialist army, still under Gallas, had departed from Alsace to the east in order to repair the disaster of Wittstock, and Charles of Lorraine was defeated by Bernhard on the Saône in June, after which Bernhard advanced vigorously against Piccolomini, the imperialist commander in Alsace. But soon Piccolomini was joined by Johann von Weert, and Bernhard retired again

In the north-east the effect of Wittstock proved but transient In 1638 Banér found himself the target of several opponents The Saxons did no more than defend their own country, but the imperialists and Bavarians uniting under Gen. Geleen manoeuvred Banér out of his strongholds on the Elbe He retreated on the Oder, but there found, not the expected assistance of Wrangel's Pomeranian army, but Gallas with the main imperial army which had hurried over from the west Banér escaped only by a stratagem Deluding Gallas with an appearance of retreat into Poland, he slipped northwards, joined Wrangel, and established himself for a time in Pomerania Gallas ruined his army by exposing it to an open winter in this desolate country, and at last retired to the Elbe

Fighting in the Netherlands and Alsace.—In 1638 the French operations in Italy, Belgium and Spain were in the main unsuccessful. In Italy the Spanish advanced to the Sesia and took Vercelli In the Low Countries Prince Thomas and Piccolomini repulsed in turn the Dutch and the French In the south the Prince of Condé led from Bayonne an invading army that was to dictate terms at Madrid, but failed ignominiously before the small frontier fortress of Fontarabia But the case was different in Alsace There Richelieu was more than ever determined to strike at the Spanish power, and there too was Bernhard, who hoped that Alsace was to be his future principality, with the survivors of Breitenfeld and Nordlingen, now in French pay under the name of the "Weimar Army" Bernhard had wintered about Basle, and began operations by taking a few towns in the Black Forest. Johann von Weert, however, fell upon him by surprise and drove him away (Feb 28). But Bernhard reassembled his adventurers and invited them to return and beat the imperialists at once The outcome was the battle of Rheinfelden, in which the redoubtable Weert, who had terrified Paris in 1636, was taken prisoner and his army dissipated (March 3) Bernhard later invested Breisach and received its surrender when the garrison had eaten the cats, dogs and rats in the place, on Dec. 17.

In the course of 1638 peace negotiations were carried on at Cologne and Hamburg, but the war still dragged on In the east, 1639 began with Banér's pursuit of the retreating Gallas Thanks to his skill the Swedish star was again in the ascendant Banér crossed the Elbe, inflicted a severe defeat on the imperialists at Chemnitz (April 14, 1638), and then after overrunning western Saxony advanced into Bohemia But he contented himself, after an unsuccessful attempt upon Prague, with thoroughly eating up the country and, as winter came on, he retired into the Saxon mountains.

France and Spain.—In 1639, as before, Richelieu's attacks on Spain, other than those directed upon Alsace and Baden, were unsuccessful In the north the French devoted this year, as they had devoted 1637 and 1638, to a methodical conquest of walled towns in view of a future *frontière de fer*. The two objectives selected, Hesdin and Thionville, were far apart, and Piccolomini, by a forced march from Liège and Huy through the Ardennes, flung himself upon the besiegers of Thionville before their "circumvallation" was completed, and being greatly superior in numbers he almost annihilated them (June 7, 1639). But on the Flemish flank Hesdin was driven to surrender On the side of the Pyrenees Condé as usual showed himself both unlucky and incapable In Italy Cardinal de La Valette died after allowing Prince Thomas to win over Savoy to the emperor's side and seeing almost every French post lost.

His successor was the duc d'Harcourt, called by his men "Cadet-la-Perle" on account of his earrings, but a bold and exceedingly competent soldier. Under him served Turenne, hitherto known only as a younger brother of the duke of Bouillon Harcourt successfully revictualled Casale, and beat the Savoyards and Imperialists in the Route de Quiers (Nov 29).

In Alsace Bernhard was carried off by a fever just as he was preparing to fight his way to a junction with Banér. Nevertheless he was fortunate in the opportunity of his death, for his dream of a duchy of Alsace had already brought him into conflict with Richelieu, and their conflict could only have ended in one way Another event of importance in this year was the episode of the Spanish fleet in the Downs. Now that the land route was imperilled the sea communications of Spain and Belgium were brought into use. A squadron sailed from Spain for the Netherlands, and, though it evaded the now powerful French navy, it was driven into English territorial waters by the Dutch. Charles I of England offered France free access to the victim if France would restore the Elector Palatine, offered Spain protection if she would furnish him with funds for his army. But the Dutch, contemptuous of his neutrality, sailed in and destroyed the fleet at anchor

In 1640 the French still kept up their four wars in Belgium, Germany, Italy and Spain But the Belgian and Spanish frontiers were no longer directly attacked The Catalans turned their arms against the old enemy Castile and Portugal declared herself independent under a king of the house of Braganza In the Low Countries Louis XIII himself presided over the siege of the important fortress of Arras, which surrendered on Aug 8

Casale and Turin.—In Italy, however, Cadet-la-Perle kept the moral ascendancy he had won in the brave action of the *Route de Quiers* In April with 10,000 men he advanced from Carignan against the 20,000 Spaniards who were besieging Casale and attacked their line of circumvallation boldly and openly on April 29. Half of Leganez's army was killed or captured After this, Harcourt promptly turned upon Prince Thomas, and then followed one of the most curious episodes in military history Thomas, himself defending Turin, was besieging the French who still held the citadel, while Harcourt, at once besieging the town and attempting to relieve the citadel, had, externally, to protect himself against Leganez's army which was reorganized and reinforced from Naples and the Papal States. Harcourt's courage and the disunion of his opponents settled the problem Their general attack of July 11 on the French lines was made not simultaneously but successively, and Harcourt repulsed each in turn with heavy losses Soon afterwards the French received fresh troops· the citadel was relieved and the town surrendered Leganez retired to Milan.

In Germany Banér's course was temporarily checked and when at last Bernhard's old army, under the duc de Longueville, crossed the Rhine and joined Banér in Thuringia, the country could not support the combined army The Weimar army retired to the Rhine valley and Banér to Waldeck. A fresh opportunity came to Banér in the winter months of 1640–41. Negotiations for peace were constantly in progress, but no result seemed to come out of them. The Diet was assembled at Regensburg. Banér suddenly moved south to surprise the Diet, for the defence of which all available troops were hurried up by the emperor The Weimar army under Guébriant joined the Swedes *en route*, and the combined army reached the objective. But a thaw hindered them and gave the emperor time to concentrate his forces, and the raid failed. On May 20 Banér, worn out by fatigue, died, and Torstensson succeeded to the command The war had now receded far from Alsace, which was firmly held by France, but Harcourt's continued success in Piedmont and the trouble to Spain caused by the Catalan and Portuguese insurrection was partly balanced by France's own difficulties in the abortive conspiracy against Richelieu.

In Dec 1641 there began at Münster and Osnabrück in Westphalia the peace negotiations which, after eight more years of spasmodic fighting, were to close this ruinous war. In 1642 Tors-

tensson crossed the Elbe and besieged Leipzig. The imperialist army, which was joined by the Saxons when their country was again the theatre of war, marched to the rescue. But Torstensson defeated them with enormous loss in the second battle of Breitenfeld (Nov. 2, 1642) But, although the Austrians feared an advance on Vienna itself, the victors waited for the fall of Leipzig and then took up winter quarters The Bavarians had advanced into the lower Rhine region in order to support, in concert with the Belgian army of Spain, a fresh outbreak in France (Cinq-Mars' conspiracy). But the Spanish were attacked and defeated before the Bavarians came up, at Hulst (Jan. 17), whereupon the Bavarians took shelter under the guns of the fortress of Jülich.

On the northern frontier of France, Harcourt, the brilliant commander of the Italian army, failed to prevent the Spaniards from capturing Lens and La Bassée, and another army was defeated and routed at Honnecourt (May 26) The Spaniards in the Milanese lost fresh ground. Louis XIII. himself conquered Roussillon Richelieu crushed the conspiracy of Cinq-Mars by executing its leaders, and Marshal de la Motte-Houdencourt held Catalonia and defeated Leganez at Lerida (Oct 7th).

The Duc d'Enghien.—Before the next campaign opened, Louis and Richelieu were dead One of the last acts of the king was to designate the young duc d'Enghien, son of the incapable Condé, general of his northern army It was no small matter to put in command a youth of 21, who might prove not merely inexperienced but also incompetent. But Enghien's victory was destined to be the beginning for the French army of a long hegemony of military Europe Melo, the Spanish general, had selected the Meuse route for his advance on Paris On it he would meet only the places of Rocroi and Rethel The young duke learned at the same moment that Louis XIII was dead and that the Spaniards had invested Rocroi With the resolution and swiftness which was to mark his whole career, he marched at once to offer them battle, though all the generals of the old school were for delay The battle took place on May 19, 1643, in a plain before Rocroi Melo's cavalry was routed, and nearly all the infantry, the best regiments in the Spanish army, stood their ground and were annihilated

But even Rocroi, under the existing conditions of warfare, was decisive only in so far as by the destruction of Spain's superiority in Belgium, it saved France from further danger from the north. The thorough establishment of the French on the Rhine and the need of co-operating with the Swedes were considered by the young general to be more important than fighting Melo in front of Brussels, and in spite of the protests of the Regent and Mazarin, he decided to attack Thionville Taking a leaf out of Melo's book, he threatened Brussels in order to draw all the defenders thither, and then suddenly turned eastward Enghien arrived on June 18, and on Aug 8, Thionville surrendered

Beyond the Rhine Guébriant was mortally wounded in the siege of Rottweil, and Rantzau, taking over the command, allowed himself to be surprised in the act of dispersing into winter-quarters, and was defeated at Tuttlingen on the headwaters of the Danube (Nov. 24).

In the East the campaign had as usual turned more upon subsistence than upon military operations. Torstensson swept through Bohemia and Moravia, his steps dogged through the devastated country by Gallas, until he reached Brünn. Thence, however, he suddenly retreated to the shores of the Baltic. For Christian of Denmark had declared war on Sweden, and threatened to isolate the Swedish forces in Germany Torstensson, therefore, wintered in Holstein. In Italy and Spain there was no event of any importance

In 1644 Gaston of Orleans began the conquest of the Dunkirk region in July, and Melo, having no army to oppose him, remained inactive. In Italy there happened nothing serious, while in Spain La Motte-Houdencourt lost Lerida, and was imprisoned by Mazarin in consequence. But the Rhine campaign is memorable for the first appearance of Turenne at the head of an army and for the terrible battle of Freiburg

Freiburg.—In Suabia Mercy's Bavarians were left to oppose Turenne, who spent the first months of the year in restoring discipline and confidence in the shaken Weimar army. But Mercy was still considerably superior in strength, and, repulsing Turenne's first inroad into the Black Forest, besieged Freiburg Turenne made one cautious attempt at relief, then waited for reinforcements These came in the shape of Enghien's army, and Enghien as a prince of the blood took over the supreme command But both armies together numbered hardly 17,000 men when Enghien and Turenne united at Breisach on Aug. 2. On the 3rd they crossed the Rhine and attacked Mercy's position, which was of great natural and artificial strength, in front and flank Three separate battles, which cost the Bavarians one-third of their force and the French no less than half of theirs, ended in Mercy's retreat (*see* FREIBURG) on Aug. 10 Enghien did not follow him into the mountains, but proceeded to the methodical conquest of the middle Rhine fortresses, leaving Turenne and the Weimar army at Spire

In the east, or rather in the north, a desultory campaign was carried on during 1644 between Torstensson and the younger Wrangel, on the one side, the Danes and Gallas on the other, and in the end Gallas retreated to Austrian territory, so completely demoralized that his army dwindled on the way from 20,000 men to 2,000. Torstensson followed him, having little to fear from the Danes. Meanwhile the prince of Transylvania, George Rakóczy, playing the part of Gabriel Bethlen his predecessor, made war upon the emperor, who not being able on that account to send fresh troops against Torstensson called for help to Maximilian of Bavaria. The Elector sent most of his own troops under Weert on the same errand—hence Mercy's defeat at Freiburg But Torstensson pressed on towards Vienna, and on Feb 24–March 6, 1645 he inflicted a crushing defeat on the Bavarians and Imperialists at Jankau near Tabor In his extremity Ferdinand offered part of Bohemia and Silesia to Maximilian in return for soldiers. But the Bavarian ruler had no more soldiers to give, for Turenne was advancing again from the Rhine

At the end of March the Weimar army marched to Heilbronn, and Rothenburg-on-Tauber, when Turenne resolved to go northward in search of supplies and recruits in the territories of his ally and cousin the landgravine of Hesse-Cassel But at this point the army, headed by Bernhard's old colonels, demanded to be put into rest-quarters, and Turenne allowing them to disperse as they wished, was surprised by Mercy and Weert—who brought his courage, if nothing else, back from the field of Jankau—and lost two-thirds of his forces. But Turenne, instead of retreating to the Rhine, installed himself in the landgravine's country, while Enghien hurried up from the Moselle to his aid The "Army of Weimar" and the "Army of France" joined forces, as in 1644, almost under the eyes of the enemy Enghien at once pushed forward from Ladenburg, by Heidelberg and Dinkelsbuhl, and found the Austro-Bavarians under Mercy entrenched in a strong position at Allerheim near Nordlingen, directly barring the way to the Danube The second battle of Nördlingen (Aug 3, 1645) was as desperately fought as the first, and had not Mercy been killed at the crisis of the day Enghien would probably have been disastrously defeated As it was, the young duke was victorious, but he had only 1,500 infantry left in rank and file out of 7,000 at the end. Soon afterwards Enghien fell ill, and his army returned to France. Turenne, left with a few thousand men, attempted in vain to hold his ground in Germany and had to make a hasty retreat to Philippsburg on the Rhine, almost the only remaining conquest of these two brilliant but costly campaigns In Flanders Gaston of Orleans conquered a number of fortresses, and his army united with that of the Dutch But the allies separated again almost at once, each to undertake the sieges which suited its own purposes best.

From Silesia Wrangel, who had succeeded Torstensson, passed into Bohemia, where he remained until the forces employed against Rakóczy and Turenne could send help to the imperialists opposed to him. He then drew away into Hesse, the Archduke Leopold and the Bavarians following suit

Turenne's Strategy.—The campaign of 1646 in Hesse up to August was as usual uneventful, each army being chiefly concerned

with its food. But at last the archduke retired a little, leaving Turenne and Wrangel free to join their forces. Turenne had no intention of repeating the experiences of Freiburg and Nordlingen. It was more profitable to attain the small objects that were sought by manoeuvre than by battle, and the choice of means practically lay between manoeuvring the enemy's army into poor districts and so breaking it up by starvation, and pushing one's own army into rich districts regardless of the enemy's army. The usual practice was the first method. Turenne chose the second.

Delayed at the opening of the year by orders from Mazarin—Turenne found it impossible to reach Hesse by the short and direct route, and he therefore made a rapid and secret march down the Rhine as far as Wesel, whence, crossing unopposed, he joined Wrangel on the upper Lahn (Aug 10) The united armies were only 19,000 strong But the imperialists, fearing to be hemmed in and starved between Turenne and the Rhine, fell back to Fulda, leaving the Munich road clear The interior of Bavaria had not been fought over for 11 years, and was thus almost the only prosperous land in desolated Germany. Turenne and Wrangel marched straight forward on a broad front, and for the rest of the year they devastated the country about Munich in order to force Maximilian to make terms An armistice was concluded in the winter, Maximilian having been finally brought to consent by an ill-judged attempt of the emperor to seduce his army. The French and Swedes wintered in southern Württemberg

In Flanders, Gaston of Orleans and Enghien took Dunkirk and other fortresses In Italy, where the Tuscan fortresses were attacked, the French were completely checked at first, until Mazarin sent a fresh corps thither and restored the balance In Catalonia Harcourt underwent a serious reverse in front of Lerida at the hands of his old opponent Leganez, and Mazarin sent Enghien, now prince of Condé, to replace him

1647 was a barren year In the Low Countries the war dissipated itself in sieges. In Italy Plessis-Praslin won an unprofitable victory over the viceroy of the Milanese on the Oglio (July 4). In Spain Condé, resuming the siege of Lerida, was repulsed and had to retire. In Germany Turenne and Wrangel parted company The latter returned to Hesse, whence he raided into Bohemia, but was driven back by the imperialists As the few obtainable supply areas gave out one by one, the Swedes gradually retired almost to the coast, but the imperialists did not follow, swerving into Hesse instead. Turenne meanwhile had had to send all his French troops to Luxemburg to help in the defence of northern France against the Spaniards The Weimar army had refused to follow him to the Meuse, and mutinied for its arrears of pay. Turenne, however, promptly seized the ringleaders and after a sharp fight disarmed the rest. Thus ignominiously Bernhard's old army vanished from the scene.

In the autumn the elector of Bavaria was reconciled to the emperor and his army re-entered the field. Turenne was therefore sent back to Germany to assist the Swedes. But winter came on before any further inroads could be made into south Germany.

The campaign of 1648 brought the decision at last. Turenne and Wrangel, having refitted their forces and united in Hesse as in 1646, steadily drove back the imperialists and Bavarians, whose 30,000 combatants were accompanied by a horde of nearly 130,000 hangers-on—men, women and children—to the Danube At Zusmarshausen (May 17) catching the enemy in the act of manoeuvring, they destroyed his rear-guard The victors advanced as far as the Inn, but Piccolomini, reorganizing the débris of the Austro-Bavarian army, checked their further progress and even drove them back to the line of the Isar. Meantime, however, the Swedish general Königsmarck, had entered Bohemia and was besieging Prague. This caused the recall of Piccolomini's army, and Turenne and Wrangel invested Munich But Mazarin ordered the French to retire into Suabia so as not to compromise the peace negotiations at the critical moment, and Wrangel followed suit. Before Königsmarck was in a position to assault Prague news came of peace Meanwhile in Artois Condé had repulsed the Spanish invasion by his brilliant victory of Lens (Aug. 5), which was a second Rocroi After the thanksgiving service for the victory at Nôtre Dame, Mazarin arrested the leaders of the *parlement* of Paris, and in a few hours the streets were barricaded and a civil war was in progress. This was the Fronde (*q.v.*), which went on for another 11 years.

THISTLE, a name, as generally employed, of vague application, being given to almost any herbaceous plant that is of a spiny character. More strictly, it is applied to the species of *Carduus,* herbs belonging to the family Compositae, with very spiny leaves, and similar bracts surrounding a head of purplish-white, tubular, five-parted flowers seated on a pitted and hairy receptacle. The fruit is surmounted by a tuft of silky-white hairs. The species, chiefly natives of Europe and western Asia, are numerous, and some are of great beauty, though, not unnaturally, looked on with disfavour by the farmer The blessed thistle is *Carduus benedictus;* lady's thistle, the leaves of which are spotted with white, is *C marianus.* The common *C lanceolatus* seems to be the most suitable prototype for the Scots thistle, though that honour is also conferred on an allied plant *Onopordon Acanthium,* the cotton thistle, remarkable for its covering of white down, a doubtful native of Great Britain, and on other species The carline thistle is *Carlina vulgaris,* a member of the same family as is also the sowthistle, *Sonchus oleraceus* The great objection to thistles from an agricultural point of view resides in the freedom with which they produce seed, and in the vigour of their underground growth, which makes their uprooting a matter of difficulty. The artichoke (*q v*) and cardoon (*q v*) are very near allies of the thistles. The safflower, *Carthamus,* another thistle, yields a serviceable dye, the burdock, *Arctium lappa,* a member of the same family, has an edible root, and numerous allied species have medicinal properties. (*See* Canada Thistle)

THISTLEWOOD, ARTHUR (1770–1820), the principal instigator of the Cato Street conspiracy, a plot formed to murder the British cabinet in 1820. A son of William Thistlewood, and born at Tupholme in Lincolnshire, young Thistlewood became a soldier and visited France and America He developed republican sympathies and on taking up his residence in London joined the Spencean Society, a revolutionary body, associated himself with James Watson (d. 1838) and other agitators, and in December 1816 helped to arrange a meeting in Spa Fields, London, which was to be followed by the seizure of the Tower of London and the Bank of England, and by a general revolution. The proposed rising failed, but the Habeas Corpus Act was suspended and Thistlewood and Watson were tried but acquitted. Thistlewood continued his intrigues and was sentenced to a year's imprisonment for challenging the home secretary, Lord Sidmouth, to a duel. After his release in May 1819, having broken away from Henry Hunt and the more moderate reformers, he prepared a new and comprehensive plot. On Feb. 23, 1820, at a time of great distress and during the unrest caused by the death of George III, the cabinet ministers had arranged to dine at the earl of Harrowby's house in Grosvenor Square. With some associates Thistlewood hired a room in the neighbouring Cato Street, collected arms and made ready to fall upon Harrowby's guests. The authorities had been informed of the plot, probably by one of the conspirators named George Edwards; officers appeared upon the scene and arrested some of the conspirators; and although Thistlewood escaped in the confusion he was seized on the following day. Tried for high treason, Thistlewood and four others were sentenced to death, and were hanged on May 1, 1820

THÖKÖLY, IMRE (Emerich), Prince (1657–1705), Hungarian statesman, was born at Késmark on the 25th of September 1657. He lost both parents while still a child. In 1670, fleeing from the dangers of Upper Hungary, where the Protestants and Imperialists were constantly in arms against each other, he took

refuge with his kinsman Michael Teleki, the chief minister of Michael Apafy, prince of Transylvania. Here he came into contact with the Magyar refugees, who had great hopes of the high-born, high-gifted youth who was also a fellow sufferer, a large portion of his immense estates having been confiscated by the emperor. The discontent reached its height when Leopold (Feb. 27, 1673) suspended the Hungarian constitution, appointed Johan Gaspar Ampringen dictator, deprived 450 Protestant clergy of their livings and condemned 67 more to the galleys. Encouraged by promises of help from Louis XIV, the Magyars now rose *pro libertate et justitia,* and chose the youthful Thököly as their leader The war began in 1679. Upper Hungary and the mining towns were soon in Thököly's possession In 1681, reinforced by 10,000 Transylvanians and a Turkish army under the pasha of Nagy-várad, he compelled the emperor to grant an armistice. Thököly's distrust of the emperor induced him to turn for help to the sultan. In the same year Thököly captured fortress after fortress from the emperor and extended his dominions to the Waag He refused the title of king offered to him by the Turks. He was buried at Nicomedia but in 1906 his relics were transferred to Hungary

See *Correspondence of Thököly* (Hung), ed by Kálmán Thaly (Budapest, 1896); V. Fraknói, *Papst Innocenz XI und Ungarn's Befreiung von der Turkenherrschaft* (Freiburg, 1902); *Memoirs of Emeric Count Teckely* (London, 1693), *Correspondence of Michael Teleki* (Hung), ed. by S Gergely (Budapest, 1905–06).

THOLOS, in Greek architecture, a circular building, with or without a peristyle, the earliest examples are the beehive tombs at Mycenae and in other parts of Greece, which were covered by domes built in horizontal courses of masonry. The Tholos at Epidaurus, built by Polycleitus (*c.* 400 B.C.), and the Tholos at Olympia, known as the Philippeion, are the most remarkable examples, and in both cases were covered with a sloping roof and not with a dome.

THOLUCK, FRIEDRICH AUGUST GOTTREU (1799–1877), German Protestant divine, was born at Breslau, on March 30, 1799 He studied at Breslau and at Berlin, where he was received into the house of the Orientalist Heinrich Friedrich von Diez (1750–1817) He came under the influence of the pietist Baron Ernst von Kottwitz (1757–1843), who became his "spiritual father," and of the historian Neander. In 1821 he was *Privatdozent* and in 1823 became professor extraordinarius of theology in Berlin. *Die wahre Weihe des Zweiflers* (1823; 9th ed, with the title *Die Lehre von der Sunde und dem Versohner,* 1870), the outcome of his own religious history, secured his commanding position as the Pietistic apologist of Evangelical Christianity In 1825, with the aid of the Prussian government, he visited the libraries of England and Holland, and on his return was appointed (in 1826) professor ordinarius of theology at Halle, the centre of German rationalism, where he afterwards became preacher and member of the supreme consistorial council. Here he sought to combine in a higher unity the learning and to some extent the rationalism of J. S Semler with the devout and active pietism of A. H. Francke, and, in spite of the opposition of the theological faculty of the university, he succeeded in changing the character of its theology. Tholuck was also one of the prominent members of the Evangelical Alliance, and few men were more widely known or more beloved throughout the Protestant world than he. As a preacher he ranked among the foremost of his time. He died at Halle on June 10, 1877.

After his commentaries (on Romans, the Gospel of John, the Sermon on the Mount and the Epistle to the Hebrews) and several volumes of sermons, his best-known books are *Stunden christlicher Andacht* (1839; 8th ed, 1870), intended to take the place of J H. D. Zschokke's standard rationalistic work with the same title, and his reply to David Strauss's *Life of Jesus* (*Glaubwurdigkeit der evangelischen Geschichte,* 1837). He published at various times valuable contributions towards a history of rationalism—*Vorgeschichte des Rationalismus* (1853–62), *Geschichte des Rationalismus* (1865), i. and a number of essays connected with the history of theology and especially of apologetics. His views on inspiration were indicated in his work *Die Propheten und ihre Weissagungen* (1860), in his essay on the "Alte Inspirationslehre," in *Deutsche Zeitschrift für christliche Wissenschaft* (1850), and in his *Gespräche über die vornehmsten Glaubensfragen der Zeit* (1846; 2nd ed., 1867).

See *Das Leben Tholucks,* by L. Witte (2 vols, 1884–86).

THOMAR, now Tomar, on the river Nabão, a tributary of the Zezere, 4 m from Paialvo railway station, which is 80 m N.E. of Lisbon by the main line to Oporto Pop (1911), 8,054. Thomar contains examples of the best Portuguese architecture from the 12th century to the 17th The ruined castle of the Knights Templar, given to that order in 1159, is said to occupy the site of the ancient Nabantia On the suppression of the Templars, King Dinis of Portugal founded the Order of Christ in 1314 The convent palace of the Knights of Christ includes a church and cloister dating from the 12th century, two cloisters and a chapter-house added in the 15th century by Prince Henry the Navigator and a very fine 16th century church built in the Manueline style by João de Castilho Other interesting buildings are the churches of Santa Maria do Olival, rebuilt in the Gothic style in 1450 on the site of an older Templar foundation; São João Baptista, also Gothic, built in 1490, but with Manueline additions; Nossa Senhora da Conceição, Renaissance of 1579; and the ruined palace of Prince Henry the Navigator, restored in the 16th century by Queen Catherine, widow of John III.

THOMAS, ST., one of the twelve apostles The name means "twin" in Aramaic, as is recognised in John xi 16 ("called Didymus"). Eusebius (*H E.* iii 1, 1) says Thomas was the evangelist of "Parthia," probably because Edessa (*q v*), where some of his bones were preserved, is sometimes called "Edessa of the Parthians" These bones were reputed to have been brought to Edessa from India, and a work known as the *Acts of Thomas* relates his missionary labours and martyrdom there. This work was originally composed in Syriac; it is indeed one of the oldest and most idiomatic monuments of Syriac literature, though it is very doubtful whether it is based on any historical facts In the 4th century it was translated into Greek, and thence into Latin, almost certainly as part of the Manichaean propaganda. The Manichaean taint was soon recognised (*e g*, by Augustine) and the *Acta Thomae* in their original form branded as heretical The view taken was that the framework, recounting the journeyings of the apostle, was historical, while the speeches and sermons contained the heresy In consequence most mss, both Greek and Latin, contain very little of the speeches while retaining the framework Even Wright's Syriac ms has been occasionally conventionalized, and the original form is only to be found in the ancient (4th or 5th century) palimpsest fragments at Sinai

The *Acts of Thomas* is a leading authority for the earliest Christianity in the countries east of the Euphrates: it was ascetic, marriage being discountenanced and all preoccupation with the things of this world discouraged In the Acts Eucharistic prayers are given, but (according to the Sinai fragments and the best Greek) only bread and water were used The Lord's Prayer is quoted in full A curious feature is that the name of the apostle is given as Judas Thomas, and it is expressly set forth that he was the twin of Jesus Christ As a tale the *Acts of Thomas* is remarkable for the real religious emotion that pervades it and for careful delineation of character. but above all for the hymn chanted by the apostle when in prison This, commonly known as the "Hymn of the Soul" (Wright, pp 238–245), is a metrical Syriac poem describing, under the parabolic form of the journey of a prince from his Eastern home to Egypt, the descent to earth and the return to its heavenly home of the soul It is often supposed to be an independent composition inserted into the *Acts,* but for this there is no real evidence In any case it is the great gem of Syriac literature

"Christians of St. Thomas" is a name often applied to the ancient Christian churches of southern India; the view taken of their history is so intimately connected with the historicity of the *Acts of Thomas* that it is convenient to treat of them here According to the tradition, St. Thomas founded the Christian churches in Malabar (south-west coast), and then crossed to Mylapur, now a suburb of Madras, where the shrine of his martyrdom, rebuilt by the Portuguese in 1547, still stands on Mt. St. Thomas, where a cross is shown with a Pahlavi inscription which may be as old as the 7th century. We know from Cosmas Indicopleustes that there were Christians of Persian (East Syrian) origin, and doubtless of Nestorian creed, in Ceylon, in Malabar,

and at Caliana (north of Bombay) before 550 In 1400 they sent to the Nestorian patriarch Simeon, who gave them fresh bishops (Assemani, *Bib Or* iii 1,590-f, *J. Theol. Stud.* xxix 155) Hard pressed by the Muslims they welcomed the Portuguese and, after much controversy, a formal union with Rome was carried through in the Synod of Diamper (1599) Syriac was to remain the ecclesiastical language, but the service books were "purified from error."

Dom R H Connolly proved in 1914 that this revision was slight in extent, and that the Malabar liturgy remained essentially a form of the Nestorian rite After a century and a half of Jesuit rule a great schism took place in 1653, those who thus became independent of Rome organizing themselves under Jacobite (Monophysite) influence (The ms of the whole Syriac Bible and the Clementine literature [12th century] then sent to Malabar from Mesopotamia was brought to Europe by Claudius Buchanan [1811] and is now in the Cambridge university library) Both this Church and the Roman obedience still flourish in Malabar.

From what has been said, the ancient Christian communities of southern India would be naturally regarded as a surviving branch of the extensive Nestorian missions, parallel to those which once flourished in Turkestan and China. But the Christians in India have come to regard St. Thomas as their founder and appeal to the *Acts of Thomas*, or documents derived from that work, in support It may be remarked that their whole knowledge of this work seems to be derived from the Latin form of the *Acta Thomae* It is claimed that the *Acta* are historical, and further, that the scene of the *Acts* is laid in southern India. Unfortunately for this view, the details in the *Acts* which point to any acquaintance with India at all are connected with the northwest and the country between India and Mesopotamia. The Indian King Gundaphar of the *Acts* is certainly meant for the historical Gondophares, whose dynasty was Parthian, though his realm included regions loosely reckoned to India. But the use of such names does not prove historicity; the name Ahasuerus does not establish the historicity of the book of Esther Moreover the greater part of the names in the *Acts of Thomas* are Mesopotamian, *e g*, the heroine, Mygdonia, is named after the river on which Nisibis stands In any case there is nothing in these Acts about caste or other prominent features of Indian life. The real value of the *Acts of Thomas*, as indicated above, is to illustrate the ideas and aspirations of the Christianity, not of India but of upper Mesopotamia, in the 3rd century A D

THOMAS, surnamed MAGISTER (*i e.*, officiorum)[1], also known as a monk by the name Theodulos Monachos, a native of Thessalonica, Byzantine scholar and grammarian and confidential adviser of Andronicus II (1282–1328) His chief work, Ἐκλογὴ Ὀνομάτων καὶ Ῥημάτων Ἀττικῶν, is a collection of selected Attic words and phrases, partly arranged in alphabetical order, compiled as a help to Greek composition from the works of Phrynichus, Ammonius, Herodian and Moeris. He also wrote scholia on Aeschylus, Sophocles, Euripides (with life), and three of the comedies of Aristophanes, the scholia on Pindar, attributed to him in two mss, are now assigned to Demetrius Triclinius. His speeches and letters deal with contemporary events.

Editions of the Ἐκλογή by F. Ritschl (1832), C. Jacobitz (1833) and C. D. Beck (1836); other works in J P Migne, *Patrologia graeca*, cxlv., *see* also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

[1]For the duties of this important office, *see* J. B. Bury (*Later Roman Empire*) (1889), i. 45.

THOMAS (d. 1100), archbishop of York, a native of Bayeux, is usually called Thomas of Bayeux. His father was a priest named Osbert, and Samson, bishop of Worcester (1086–1112), was his brother Owing largely to the generosity of Odo, bishop of Bayeux, Thomas studied in France, Germany and Spain and then became one of Bishop Odo's officials and after 1066 one of William the Conqueror's chaplains, or secretaries. In 1070 he succeeded Aldred as archbishop of York, but declining to promise obedience to the archbishop of Canterbury, Lanfranc refused to consecrate him King William, however, induced him to submit and he was consecrated, but his profession of obedience was to Lanfranc personally and not to the archbishops of Canterbury.

In 1071 both archbishops travelled to Rome for their palls and while there Thomas wished Pope Alexander II. to decree the equality of the sees of Canterbury and York. The pope, however, referred the dispute to a council of English prelates which met at Windsor at Whitsuntide in 1072 It was then decided that the archbishop of Canterbury was the superior of the archbishop of York, who had no rights south of Humber, but whose province included Scotland This decision did not end the dispute which broke out again in 1092 and 1093 when Thomas protested against what he thought infringements of his archiepiscopal rights The first of these occasions was over the dedication of the cathedral built by Remigius at Lincoln and the second was over the consecration of St Anselm to the archbishopric of Canterbury. He died at York on Nov. 18, 1100.

THOMAS, ALBERT (1878–), French statesman, was born on June 16, 1878, at Champigny-sur-Marne, near Paris His father was a baker who by great sacrifices enabled his son to receive a college and university education Scholarships enabled him to travel in Russia and Germany A sequel to this was his book *Le syndicalisme allemand* (1903) in which his socialist faith was propounded for the first time.

When, in 1904, Jean Jaurès launched *l'Humanité* he appointed Thomas assistant editor Thomas played an important part as a right-wing leader in the General Confederation of Labour (C G.T) He published in 1908 a volume on the Second Empire in Jaurès' great *Histoire socialiste*

He was elected to the Chamber for his native city in May 1910 and again in 1914, becoming one of the most active and prominent Socialist members

He joined his regiment in 1914 After he had seen a few weeks of war service, the Government summoned Thomas and two other Socialists, Jules Guesde and Marcel Sembat, to organize the production of munitions In May 1915 he entered the cabinet as under-secretary for armaments and also joined the Briand Ministry which followed at the end of the year Towards the end of 1916 he became minister of munitions, retaining this post in the Ribot Ministry which followed. In April 1917 he was sent to Russia, where he remained for several months and succeeded in persuading Kerensky to undertake the ineffectual "great offensive" against the Central Powers

Meanwhile in France the struggle was becoming very bitter between the majority (pro-war) and the minority (internationalist) sections of the French Socialist party, culminating in the Stockholm Conference Leader, with Renaudel and Sembat, of the majority party, Albert Thomas was also a strong advocate of the independence of Czechoslovakia and Poland and the creation of a "Great Serbia" and a "Great Rumania." Since this "majority wing" policy was opposed by many Socialists, particularly in the Paris district, Thomas decided not to stand again in the Paris suburbs and resigned the mayoralty of Champigny. At the elections of Nov. 16, 1919, he was returned as a Socialist in the Tarn, Jaurès' former constituency.

During the first session of the International Labour Conference, held at Washington at the end of the year, Thomas was provisionally appointed director of the International Labour Office (League of Nations) by its governing body; the appointment was confirmed at the governing body's second meeting held in Paris in Jan. 1920. Apart from the organization and conduct

of the administration and scientific work of the Office, he has been indefatigable in his personal efforts to secure national ratifications of conventions adopted by the International Labour Conference In 1921 the claims of his work at Geneva led him to resign his seat in the Chamber of Deputies, but he has remained a member of the "right" section of the French Socialist party. As director of the International Labour Office he has played a pre-eminent part in the advance and maintenance of labour standards throughout the world To the present edition of the *Encyclopædia Britannica*, M Thomas contributes articles on CO-OPERATION and JAURÈS, JEAN.

THOMAS, ARTHUR GORING (1850–1892), English composer, was born at Ratton Park, Sussex, on Nov. 20, 1850, and educated at Haileybury College He studied music in Paris under Durand and at the Royal Academy of Music under Ebenezer Prout and Arthur Sullivan while at a later period he received some instruction in orchestration from Max Bruch The performance at the Royal Academy of a selection from *The Light of the Harem* (libretto by Clifford Harrison), induced Carl Rosa to commission him to write *Esmeralda* (libretto by T. Marzials and A Randegger), which was successfully produced at Drury Lane on March 26, 1883 Two years later it was given in German at Cologne and Hamburg, and in 1890 (in French) at Covent Garden On April 16, 1885 Rosa produced at Drury Lane Thomas's fourth and best opera, *Nadeshda* (libretto by Julian Sturgis), a German version of which was given at Breslau in 1890 Besides his dramatic works Thomas's chief compositions were a psalm, "Out of the Deep," for soprano solo and chorus (London, 1878), a choral ode. "The Sun Worshippers" (Norwich, 1881), and a suite de ballet for orchestra (Cambridge, 1887) Goring Thomas occupies a distinct place among English composers of the 19th century His music, which shows traces of his early French training, reveals a great talent for dramatic composition and a real gift of refined and beautiful melody He died on March 20, 1892

THOMAS, AUGUSTUS (1857–), American playwright, was born in St Louis (Mo), Jan 8, 1857 He was educated in the public schools, served as a page boy in the Missouri Legislature and in Congress, for several years worked in railway freight offices, and, after serving as writer and illustrator for various newspapers, became in 1886 part editor and proprietor of the Kansas City (Mo) *Mirror*

The success in New York and on the road of *The Burglar* (1889), an elaboration of the earlier one-act piece, and of *A Man of the World* (1883) used by Maurice Barrymore, induced A M Palmer of the Madison Square Theatre to offer the young playwright the post left vacant by the retirement of Dion Boucicault, and under Palmer's management *Alabama* (1891) was produced, a play which contributed to the removal of sectional prejudice resulting from the Civil War Thenceforth Thomas was one of the most prolific and successful of American playwrights. Other dramatic successes by him which made use of native materials were *In Mizzoura* (1893), *The Hoosier Doctor* (1898), *Arizona* (1898), and *The Copperhead* (1917). Other outstanding plays, chiefly in the vein of light comedy or romance, were *Oliver Goldsmith* (1900), *The Earl of Pawtucket* (1903), *Mrs Leffingwell's Boots* (1905) and *The Witching Hour* (1907). An autobiographical volume *The Print of My Remembrance* appeared in 1922

THOMAS, GEORGE (*c* 1756–1802), British military adventurer in India Thomas was born of poor parentage in Ireland in 1756, deserted from the British Navy in Madras, and made his way north to Delhi, where he took service under the begum Samru of Sardhana He then served Appa Rao, a Mahratta chieftain, and subsequently set up an independent kingdom of his own in Hariana with his capital at Hansi. He dreamed of conquering the Punjab, and fought one of his best campaigns against the Sikh chiefs; but he was finally defeated and captured by Sindhia's army under General Perron (*q v.*). He died on his way down the Ganges on Aug 22, 1802.

See Francklin, *Military Memoirs of Mr. George Thomas* (1803), Compton, *Military Adventurers of Hindustan* (1892).

THOMAS, GEORGE HENRY (1816–1870), American general, was born in Southampton county (Va), on July 31, 1816. He graduated at West Point in 1840, served as an artillery subaltern in the war against the Seminole Indians in Florida (1841), and in the Mexican War at the battles of Fort Brown, Resaca de la Palma, Monterey and Buena Vista, receiving three brevets for distinguished gallantry in action From 1851 to 1854 he was an instructor at West Point In 1855 he was appointed by Jefferson Davis, then secretary of war, a major of the 2nd cavalry. His regimental superiors were A S Johnston, R E Lee and Hardee All three resigned at the outbreak of the Civil War Thomas finally decided to adhere to the United States. He was promoted in rapid succession to be lieutenant colonel, colonel in the regular army, and brigadier general of volunteers

In command of an independent force in eastern Kentucky, on January 19, 1862, he attacked the Confederate Gen Zollicoffer at Mill Springs, and gained the first important Union victory in the west. He served under Buell and was offered, but refused, the chief command in the anxious days before the battle of Perryville Under Rosecrans he was engaged at Stone River and was in charge of the most important part of the manoeuvring from Decherd to Chattanooga At the battle of Chickamauga (*q v*) Sept 19, 1863, he gained the name of "The Rock of Chickamauga," because of his firmness He succeeded Rosecrans in command of the Army of the Cumberland shortly before the great victory of Chattanooga (*q v*), in which Thomas and his army played a most conspicuous part, his divisions under Sheridan, Wood and Baird carrying Missionary Ridge in superb style When J B Hood broke away from Atlanta in the autumn of 1864, menaced Sherman's long line of communications and endeavoured to force Sherman to follow him, Sherman left to Thomas the difficult task of dealing with Hood At the battle of Franklin, Nov 30, 1864, Thomas's force, under Gen Schofield, checked Hood long enough to cover the concentration at Nashville (*q v*) Thomas attacked (Dec 15–16, 1864) and inflicted on Hood the worst defeat sustained in the open field by any army on either side during the war For this Thomas was made a major-general in the regular army and received the thanks of Congress. After the Civil War he commanded military departments in Kentucky and Tennessee until 1869, when he was placed over the division of the Pacific with headquarters at San Francisco He died there on March 28, 1870

See George H Thomas, "Union Portraits," *Atlantic Monthly*, 1914, *Sketch of General G H Thomas*, R. W Johnson, *Memoir of Major-General George H Thomas*, Van Horne, *The Life of Major-General George H Thomas.*

THOMAS, ISAIAH (1749–1831), American printer, was born in Boston, Mass , on Jan 19, 1749 He was apprenticed in 1756 to Zechariah Fowle, a Boston printer, with whom, after working as a printer in Halifax, N S, Portsmouth, N H, and Charleston, S.C., he formed a partnership in 1770 He issued in Boston the *Massachusetts Spy* three times each week, then (under his sole ownership) as a semi-weekly, and beginning in 1771, as a weekly which soon espoused the Whig cause and which the government tried to suppress On April 16, 1775 (three days before the battle of Concord, in which he took part) he took his presses and types from Boston and set them up at Worcester, where he was postmaster for a time, here he published and sold books and built a paper-mill and bindery, and continued the paper until about 1802 except in 1776–78 and in 1786–88 The *Spy* supported Washington and the Federalist party In Boston Thomas published, in 1774, the *Royal American Magazine*, which was continued for a short time by Joseph Greenleaf, and which contained many engravings by Paul Revere, and in 1775–1803 the *New England Almanac*, continued until 1819 by his son He set up printing houses and book stores in various parts of the country, and in Boston, with Ebenezer T Andrews, published the *Massachusetts Magazine*, a monthly, from 1789 to 1793 At Walpole, N.H , he published the *Farmer's Museum* About 1802 he gave over to his son, Isaiah Thomas, Jr , his business at Worcester including the control of the *Spy* Thomas founded in 1812 the American Antiquarian Society He died in Worcester on April 4, 1831

His *History of Printing in America, with a Biography of Printers,*

and an Account of Newspapers (1810; 2nd ed, 1874, with a memoir by his grandson B. F. Thomas) is an important work, accurate and thorough *See* also "Diary of Isaiah Thomas, 1805–28" in *Transactions of the American Antiquarian Society*, vol ix. and x. (1909), and C L Nichols, "Isaiah Thomas and his Worcester Imprints" in *Proceedings of the American Antiquarian Society*, New Series, vol. xiii. (1900).

THOMAS, JAMES HENRY (1878–), British Labour leader, was born at Newport, Mon, on Oct 3, 1878 He started work as an errand boy at the age of 9 and was later employed by the Great Western railway as an engine cleaner; he rose rapidly and soon became a power in Swindon (the G.W.R. headquarters) both as a trade unionist and in local government. By 1910 he had become president of the Amalgamated Society of Railway Servants and played a leading part in its reorganization as the National Union of Railwaymen of which he was appointed general secretary after the great railway strike of 1911 Under him the N U R became the leader in the policy of "industrial" or "all grades" as against "craft" trade unionism

Thomas early took the view that larger labour aspiration could be realized only through political action, and was an opponent both of syndicalism and of communism. He was elected member for Derby in 1910 and appointed to the privy council in 1917 He refused to enter the Coalition government. He was secretary for the colonies in the Labour Government of 1924. From the first Thomas was closely associated with the management of the British Empire exhibition at Wembley Thomas was president and chairman of the parliamentary committee of the Trades Union Congress (1920–21) and president of the International Federation of Trade Unions (1920–24).

In the MacDonald cabinet of 1929 he became lord privy seal. This office, to which no departmental duties were attached, was chosen so that he might act as deputy leader for his chief in the House of Commons and preside over the prime minister's special cabinet committee on unemployment

THOMAS, PHILIP EDWARD (1878–1917), British author and poet, was born on March 3, 1878, and educated at St. Paul's School and at Lincoln college, Oxford His first book was a volume of nature studies, *The Woodland Life* (1897), followed by *Horae Solitariae* (1902), and numerous other works. Among a good many miscellaneous works should be noted his critical studies of *George Borrow* (1912); *Swinburne* (1912); and *Walter Pater* (1913), and a volume of stories, *Four-and-Twenty Blackbirds* (1915) But his prose work, though its quality is undoubted, was done to order, and shows signs of constraint as to subject and time. A collection of his prose fragments appeared in 1928, under the title of *The Last Sheaf;* some of these were written under less exacting conditions, and allow more scope to his leisurely and precise genius. It was not till middle age that, under the influence of Robert Frost, the American poet, Thomas discovered himself as a poet, and soon after came the War. Thomas enlisted in 1915, and with freedom from routine literary work became extremely fluent. His verse was first written under the name of "Edward Eastaway" and a volume of *Poems* under his own name appeared in 1917. He was killed in France on April 9, 1917 His poetry is not sharply distinguished from his prose; the rhythms are quiet and unstressed Pre-eminently a poet of the country, when he was killed, as De la Mare has said "there was shattered a mirror of England."

THOMAS, SIDNEY GILCHRIST (1850–1885), British inventor, was born on April 16, 1850, at Canonbury, London. As a police court clerk he found time to study chemistry at the Birkbeck Institute He set himself to solve the problem of separating phosphorus from iron in the Bessemer converter, and by the end of 1875 he was convinced that he had discovered a method The method was tested by his cousin, P. C. Gilchrist, at the Blaenavon works, and found effective In March 1878 the first public announcement of the discovery was made at the meeting of the Iron and Steel Institute; and a paper was written by Thomas and Gilchrist on the "Elimination of Phosphorus in the Bessemer Converter" for the autumn meeting of this institute, but was not read till May 1879 Thomas, however, interested E. W Richards, the manager of Bolckow, Vaughan & Co's works at Cleveland, Yorkshire, whom he interested in the process, and from this time the success of the invention was assured and domestic and foreign patents were taken out. The "basic process" invented by Thomas was especially valuable on the continent of Europe, where the proportion of phosphoric iron is much larger than in England, and both in Belgium and in Germany the name of the inventor became more widely known than in his own country Thomas died in Paris on Feb. 1, 1885.

See *Memoirs and Letters of Sidney Gilchrist Thomas* (1891), ed. by R. W. Burnie.

THOMAS, THEODORE (1835–1905), American musician, was born in Essen, Germany, on Oct 11, 1835. His first public appearance as a violinist was made at the age of five He was taken to America by his parents in 1845, and became first violin in the orchestra that accompanied Jenny Lind (1850), Sontag (1852) and Grisi and Mario (1854) In 1862 he began to organize his own orchestra, and in 1864 he inaugurated the series of Irving Hall symphony concerts, which for 14 years were regarded as one of the great musical institutions of New York city To Theodore Thomas is largely due the popularization of Wagner's works in America, and it was he who founded the Wagner Union in 1872 In 1888, Thomas organized the Chicago Symphony orchestra which has continued to be one of the foremost organizations of its class in the world. In 1928 this orchestra possessed a liberal endowment and its own symphony hall He died Jan 4, 1905, in Chicago.

See biography by George P. Upton

THOMAS À KEMPIS (*c.* 1380–1471), the name by which the Augustinian canon and writer Thomas Hammerken (Hammerchen, Malleolus) is commonly known. He was born in 1379 or 1380 in the town of Kempen, near Dusseldorf, in one of the many patches of territory between the Meuse and the Rhine belonging to the archiepiscopal principality of Cologne "Ego Thomas Kempis," he says in his chronicle of the monastery of Mount St Agnes, "scholaris Daventriensis, ex diocesi Coloniensi natus." His father was a poor hard-worked peasant, his mother "ad custodiam rei domesticae attenta, in opere alacris, in victu sobria, in potu abstemia, in verbo pauca, in factis pudica," as her son fondly says, kept a dame's school for the younger children of the town John and Gertrude Hammerken had two sons, John and Thomas, both of whom found their way to Deventer, and thence to Zwolle and to the convent of Mount St. Agnes. Thomas reached Deventer when he was barely twelve years old, was taught by a dame the beginnings of his learning, and in a few months to his great joy entered the classes of Florentius Radewyn After the fashion of the time he was called Thomas from Kempen, and the school title, as was often the case then, pushed aside the family name Thomas Hammerken was forgotten; Thomas à Kempis has become known to the whole Christian world.

The school at Deventer had become famous long before Thomas à Kempis was admitted to its classes. It had been founded by Gerhard Groot (*q v*), a wealthy burgher who had been won to pious living mainly through the influence of Ruysbroeck, the Flemish mystic. At Deventer, in the midst of this mystical theology and hearty practical benevolence, Thomas à Kempis was trained. Gerhard Groot was his saintly ideal. Florentius Radewyn and Gerhard's other early disciples were his heroes; their presence was his atmosphere, the measure of their lives his horizon. But he was not like them, he was not an educational reformer like Radewyn, nor a man of affairs like Gerhard. He liked books and quiet corners all his days, he says; and so, when conviction of sin and visions of God's grace came to him in the mediaeval fashion of a dream of the anger and forgiveness of the Virgin, Florentius told him that a monk's life would suit him best, advised him to join the Augustinian order, and sent him to Zwolle to the new convent of Mount St. Agnes, where his brother John was prior. Thomas was received there in 1399, professed the vows in 1407, received priest's orders in 1413, became sub-prior in 1425 and died on Aug. 8, 1471, at the age of ninety-one.

Works.—The convent of Mount St. Agnes was poor, and most of the monks had to earn money to support their household by copying MSS. Thomas was a most laborious copyist; missals, books of devotion and a famous MS. Bible were written by him.

He also wrote a large number of original writings, most of them relating to the convent life, which was the only life he knew. He wrote a chronicle of the monastery and several biographies—the life of Gerhard Groot, of Florentius Radewyn, of a Flemish lady St. Louise, of Groot's original disciples; a number of tracts on the monastic life—*The Monk's Alphabet, The Discipline of Cloisters, A Dialogue of Novices, The Life of the Good Monk, The Monk's Epitaph, Sermons to Novices, Sermons to Monks, The Solitary Life, On Silence, On Poverty, Humility and Patience;* two tracts for young people—*A Manual of Doctrine for the Young,* and *A Manual for Children;* and books for edification—*On True Compunction, The Garden of Roses, The Valley of Lilies, The Consolation of the Poor and the Sick, The Faithful Dispenser, The Soul's Soliloquy, The Hospital of the Poor* He also left behind him three collections of sermons, a number of letters, some hymns and the famous *Imitatio Christi* (though his authorship of this has been disputed).

Character.—These writings help us to see the man and his surroundings, and contemporary pious records make him something more than a shadow We see a real man, but a man helpless anywhere save in the study or in the convent—a little fresh-coloured man, with soft brown eyes, who had a habit of stealing away to his cubiculum whenever the conversation became too lively; somewhat bent, for it is on record that he stood upright when the psalms were chanted, and even rose on his tiptoes with his face turned upwards, genial, if shy, and occasionally given to punning, as when he said that he preferred Psalmi to Salmones; a man who perhaps led the most placid uneventful life of all men who ever wrote a book or scribbled letters His brethren made him oeconomiae prefectus, but he was too "simple in worldly affairs" and too absent-minded for the post, and so they deposed him and made him sub-prior once more. And yet it is this placid kindly fresh-coloured old man who has come down to us as the author of that book the *Imitation of Christ,* which has been translated into more languages than any other book save the Bible, and which has moved the hearts of so many men

On the controversy as to the author of the *Imitatio, see* the article IMITATION OF CHRIST *See* also James Williams, *Thomas of Kempen* (1910). The classical edition of the works of Thomas à Kempis by Sommalius—*Thomas Malleoli à Kempis opera omnia* (3 vols in 1, 1607)—has been many times reprinted A critical edition in 8 vols by M J Pohl has also been undertaken. The best accounts in English of Thomas à Kempis are those by S. Kettlewell (1882) and F R Cruise (1887), written from the Protestant and the Catholic standpoints respectively. A penny tract by F. R. Cruise, entitled *Outline of the Life of Thomas à Kempis* (1904), contains substantially all that is known concerning him (T M Li)

THOMASIUS, CHRISTIAN (1655–1728), German jurist and publicist, was born at Leipzig on Jan. 1, 1655, and was educated by his father, Jakob Thomasius (1622–1684), at that time head master of the Thomasschule. Through his father's lectures Christian came under the influence of the political philosophy of Hugo Grotius and Samuel Pufendorf, and continued the study of law at Frankfort-on-Oder. In 1684 he commenced the career of professor of natural law at Leipzig, and soon attracted attention by his abilities, but particularly by his daring attack upon traditional prejudices, in theology and jurisprudence In 1687 he made the daring innovation of lecturing in German instead of Latin, and in the following year published a monthly periodical (*Scherzhafte und ernsthafte, vernünftige und einfältige Gedanken uber allerhand lustige und nutzliche Bucher und Fragen*) taking the side of the Pietists in their controversy with the orthodox, and defending mixed marriages of Lutherans and Calvinists In consequence of these and other views, he was denounced from the pulpits, forbidden to lecture or to write (May 10, 1690), and his arrest was ordered The latter he escaped by flight to Berlin, and the elector Frederick III. offered him a refuge in Halle, with a salary of 500 talers and the permission to lecture. He took part in founding the university of Halle (1694), where he became second and then first professor of law and rector of the university. He died on Sept. 23, 1728. In theology Thomasius was a believer in the necessity of revealed religion for salvation.

Thomasius's most popular and influential German publications were his periodical already referred to (1688–89); *Einleitung zur Vernunftlehre* (1691, 5th ed 1719); *Vernunftige Gedanken uber allerhand auserlesene und juristische Handel* (1720–21); *Historie der Weisheit und Torheit* (3 vols, 1693), *Kurze Lehrsatze von dem Laster der Zauberei mit dem Hexenprozess* (1704), *Weitere Erlauterungen der neueren Wissenschaft anderer Gedanken kennen zu lernen* (1711)

Wagner, *Thomasius, ein Beitrag ur Wurdigung seiner Verdienste* (1872); Nicoladoni, *Christian Thomasius. Ein Beitrag zur Geschichte der Aufklarung* (Berlin, 1888); and E. Landsberg, *Zur Biographie von Christian Thomasius* (1894).

THOMAS OF CELANO, Franciscan friar and disciple and biographer of St. Francis of Assisi. Born at Celano in the Abruzzi, he joined St Francis probably about 1214, and he appears to have been one of the first band of friars who went into Germany He was commissioned by Gregory IX to write the Life of St. Francis, and in 1229 he completed the *First Legend;* in 1247 at the command of the minister general he composed the *Second Legend,* and a few years later the *Tract on the Miracles of St. Francis.* He also composed in 1255 the *Legend of St Clare;* and he is one of those to whom the sequence *Dies irae* is attributed.

Thomas of Celano's writings on St Francis have been critically edited by E d'Alençon in 1906. An English translation (*The Lives of S. Francis of Assisi by Brother Thomas of Celano*) by A G. Ferrers Howell appeared in 1908. *See* FRANCIS OF ASSISI (E. C. B)

THOMAS OF ERCELDOUNE, called also THE RHYMER, and sometimes given the surname of LEARMONT (*fl.* ? 1220–? 1297), poet and prophet in the legendary literature of Scotland The historical person of that name figures in two charters of the 13th century, and from these it appears that he owned lands in Erceldoune (now Earlstoun), in Berwickshire, which were made over by his son and heir on Nov. 2, 1294, to the foundation of the Holy Trinity at Soltra (or Soutra) on the borders of the same county This would imply that Thomas the Rhymer was already dead, but J A H Murray, who edited *The Romance and Prophecies* (E E T S, 1875), thinks that he was living three years later in a Cluniac priory in Ayrshire. He figures in the works of Barbour and Harry the Minstrel as the sympathizing contemporary of their heroes, and Walter Bower, who continued the *Scotichronicon* of Fordun, tells how he prophesied the death of Alexander III in 1285

In the folk-lore of Scotland his name is associated with numerous fragments of verse of a gnomic and prophetic character. The romance of Thomas and the elf-queen was attributed to Erceldoune by Robert Mannyng de Brunne, but the earliest text, in the Auchinleck ms. in the Advocates' library, Edinburgh, is in a dialect showing southern forms, and dates from the beginning of the 14th century. It may be based on a genuine work of Thomas, a version by him of the widely diffused Tristan Saga The most widely accepted opinion is that it is a translation of a French original.

See J A H Murray's edition of *The Romance and Prophecies* (E E T S, 1875); Brandl's *Thomas of Erceldoune* (Berlin, 1880), and Kolbing's *Die nordische und die englische Version der Tristransage* (Heilbronn, 1882); also McNeill's *Sir Tristrem* (S T S, 1886), Lumby's *Early Scottish Prophecies* (E E T S, 1870), and the reprint of the *Whole Prophesie of Scotland* (1603) by the Bannatyne Club (1833); J. Geddie, *Thomas the Rymour and his Rhymes* (Edinburgh, 1920).

THOMAS OF MARGĀ, a Nestorian bishop and author of an important monastic history in Syriac, who flourished in the 9th century A D. He was born early in the century, probably of Persian parents, in the region of Salakh to the north-east of Mosul As a young man he became in 832 a monk of the famous Nestorian monastery of Beth 'Ābhē, about 25 m due east of Mosul when he acted as secretary to Abraham, who had been abbot of Beth 'Ābhē, and was catholicus (patriarch) of the Nestorians from 837 to 850 Thomas was promoted by Abraham to be bishop of Margā, and afterwards to be a metropolitan of Beth Garmai It was during the period of his life at Beth 'Ābhē and his bishopric that he composed *The Book of Governors,* which is in the main a history of his own monastery, but includes lives of holy men in other parts of Mesopotamia and elsewhere.

The Book of Governors has been edited with an English translation and a copious introduction by E W Budge (2 vols, London, 1893)

There is a later edition by P. Bedjan (Paris, 1901).

THOMASON, GEORGE (d. 1666), English book and tract collector, was a London bookseller, who is famous for having brought together a great collection of books and tracts published during the time of the Civil War and the Commonwealth; this was formerly called the "King's Pamphlets," but is now known as the "Thomason Collection." He possessed nearly 23,000 separate publications in 1662, and having arranged these in chronological order he had them bound in 1,983 volumes The collection was bought in 1761 from his descendants by George III, who presented it to the British Museum He died in April 1666

THOMASVILLE, a city of south-western Georgia, U S A, the county seat of Thomas county, 12 m. from the Florida State line, on Federal highway 84, and served by the Atlanta, Birmingham and Coast and the Atlantic Coast Line railways Pop 8,196 in 1920, 53% negroes, estimated locally at over 11,000 in 1928. The city is beautifully situated on a ridge 273 ft above sea-level, in the yellow-pine belt of the State, and has a mild and equable climate It is famous for its rose gardens, and its "big oak" has a spread of 110 ft Thomasville is one of the oldest winter resorts in the South It was settled about 1825, incorporated as a town in 1831 and chartered as a city in 1889.

THOMOND, EARL AND MARQUESS OF, Irish titles borne by the great family of O'Brien, the earldom from 1543 to 1741 and the marquessate from 1800 to 1855 Thomond, or Tuaidh-Muin, was one of the three principalities of Munster, forming the northern part of the province Its earls were descended from Turlough O'Brien (*c* 1009–1086), king of Munster, and through him from the celebrated king of Ireland, Brian Boroimhe Turlough's descendants, Conchobhar O'Brien (d 1267) and Brian Ruadh O'Brien (d. 1276), kings of Thomond, were both typical Irish chieftains Conchobhar's tomb and effigy with a crown are still to be seen in the ruined abbey of Corcomroe, Co. Clare. His descendant Conor O'Brien (d 1539), prince of Thomond, took part in the feud between the great families of Fitzgerald and Butler and was the last independent prince of Thomond. Conor's brother, MURROUGH O'BRIEN (d 1551), prince of Thomond, the succeeding chief of the race, gave up his "captainship, title, superiority and country" to Henry VIII in 1543, when he was created earl of Thomond By special arrangement the earldom descended, not to his son Dermod, but to his nephew, Donough, who became the 2nd earl Dermod, however, inherited the barony of Inchiquin, which was conferred upon his father at the same time as the earldom

CONOR O'BRIEN, the 3rd earl (*c* 1534–*c.* 1582), was for some years at the outset of his career, harassed by the attacks of his discontented kinsmen. Then in his turn he rose against the English, but was defeated and fled to France; in 1571, however, he was pardoned and formally surrendered his lands

DONOUGH O'BRIEN, the 4th earl (d 1624), called the "great earl," was the son and successor of the 3rd earl He served England well in her warfare with the rebellious Irish during the closing year of Elizabeth's reign and was made president of Munster in 1605 The 8th earl, Henry (1688–1741), was created an English peer as Viscount Tadcaster. When he died the earldom of Thomond became extinct.

The estates of the earldom descended to the last earl's nephew, PERCY WYNDHAM (*c.* 1713–1774), a younger son of Sir William Wyndham, Bart He took the additional name of O'Brien and was created earl of Thomond in 1756 When he died unmarried the title again became extinct

In 1800 MURROUGH O'BRIEN, 5th earl of Inchiquin (*c.* 1724–1808), was created marquess of Thomond His brother James, the 3rd marquess (*c.* 1768–1855), was an officer in the navy and became an admiral in 1853. When he died the marquessate became extinct.

See John O'Donoghue, *Historical Memoirs of the O'Briens* (Dublin, 1860).

THOMPSON, FRANCIS (1859–1907), English poet, born at Preston on Dec. 18, 1859, was the son of Charles Thompson, a doctor, and the nephew of Edward Healy Thompson, the friend of Manning and professor of English literature at Dublin His father becoming a convert to Roman Catholicism, Francis was educated in the Catholic faith at Ushaw college, and in 1866 he proceeded to Owen's college, Manchester, to study medicine. He took little interest in the work however, and having thrice failed in his examinations, he went to London in Nov. 1885, to seek his fortune. There he fell into great destitution; ill health compelled him to take to opium, and after five years of misery, he obtained some light employment in the shop of a London bootmaker, where he found sufficient leisure to write his first poems. These he despatched to Wilfrid Meynell, then editor of *Merrie England,* who, struck with their great merit, arranged for immediate publication At the same time the Meynells sought out the young author, whom they found on the verge of starvation, and after persuading him to enter a hospital, they aided him throughout his long convalescence, and procured the publication of his first volume of poems in 1893. The volume quickly attracted the attention of sympathetic critics, notably Coventry Patmore, who praised it in the *Fortnightly Review* (Jan. 1894)

Much of Francis Thompson's verse is reminiscent of Crashaw's, but the beauty and splendid inventiveness of his diction were immediately recognized as giving him a unique place among his contemporaries Persistent ill health limited his output, but *Sister Songs* (1895) and *New Poems* (1897) confirmed the opinion formed of his genius The former, dedicated to the children of Mrs Meynell, was devoted mainly to descriptions of the days when he was an outcast; the latter, which contains some of his finest verse, indicates the influence of the older mystical poets From 1893–97, Thompson lived, with short intervals, near the Franciscan monastery in Pantasaph, North Wales, and later he spent much time at the Capuchin monastery, Tanlasapt. He died in London on Nov. 13, 1907, and was buried at Kensal Green He gave evidence of great power as a prose writer in his contributions to the *Academy* and the *Athenaeum,* and in his treatise *Health and Holiness* (1905), but it is mainly as a poet that he is remembered

Among his work there is much that may justly be termed eccentric, especially the use of poetically compounded neologisms; but nothing can be more simply beautiful than "The Daisy," nothing more intimate or reverent than his poems about children, or more magnificent than "The Hound of Heaven"

Apart from the works above mentioned Thompson wrote. *Life of Ignatius Loyola* (1909); *Life of John Baptist de la Galle* (1911) and *Essay on Shelley* (1909)

See also the *Athenaeum,* obit by Wilfrid Meynell, since reprinted in Thompson's *Selected Poems* (1908), Wilfrid Blunt in the *Academy,* Nov 23, 1907, the *Dublin Review,* cxlii, art by Alice Meynell, E V. Lucas, *One Day and Another* ("A Rhapsodist at Lords") (1909); Floris Delattre in *Revue Germanique,* July–Aug. 1909, K Rooker, *Francis Thompson* (1912), G. A Beacock, *F. Thompson* (1912), J. Thompson (1923) pp 159; and the authoritative biography, E. Meynell, *The Life of Francis Thompson* (1916), pp. 360.

THOMPSON, SIR HENRY (1820–1904), English surgeon, was born at Framlingham, Suffolk, on Aug 6, 1820. He graduated in medicine at University college, London, in 1851, and subsequently became assistant surgeon (1853), full surgeon (1863), professor of clinical surgery (1866), and consulting surgeon (1874) to University College hospital In 1884 he became professor of surgery and pathology in the Royal College of Surgeons, which in 1852 awarded him the Jacksonian prize for his *Pathology and Treatment of Stricture of the Urethra,* and again in 1860 for his *Health and Morbid Anatomy of the Prostate Gland* Specializing in the surgery of the genito-urinary tract, he acquired a high reputation He performed the operation of lithotomy with success on the king of the Belgians in 1863 Ten years later he carried out a similar operation on the emperor Napoleon.

In 1874, he helped to found the Cremation Society of England, of which he was the first president In 1892 he was instrumental in procuring the appointment of a committee to enquire into the methods of death certification. Thompson was a man of many interests, an amateur painter, a collector of China and a novelist. Thompson was knighted in 1867, and received a baronetcy in 1899. He died on April 18, 1904

Of his more important works, *Clinical Lectures on Diseases of*

the Urinary Organs (1868) passed through eight editions, *The Diseases of the Prostate* through six, *Cremation* (1874) through four, and *Food and Feeding* through twelve.

THOMPSON, SIR JOHN SPARROW (1844–1894), Canadian jurist and statesman, was born at Halifax, Nova Scotia, on Nov. 10, 1844, of Irish descent. In 1877 he was elected to the local legislature for Antigonish as a Conservative, and in 1878 became attorney-general. In May 1882 he became premier, but in June was defeated at the general election, though retaining his own seat, and in July was made a judge of the provincial Supreme Court In September 1885, he was appointed minister of justice in the Federal cabinet, and soon after was elected member for Antigonish. In 1886 he successfully defended in the Federal parliament the hanging of Louis Riel (*q.v.*), which had greatly angered the French Roman Catholics; in 1887–1888, together with Mr. Joseph Chamberlain and Sir Charles Tupper, he arranged a Fisheries Treaty with the American commissioners, which was afterwards thrown out by the United States Senate. During the following years he defended the government with great skill in various politico-religious disputes, and in November 1892 he became premier of Canada. He died suddenly on Dec. 12, 1894, at Windsor Castle, a few minutes after having been sworn in by Queen Victoria as a member of the privy council.

His *Life* has been written by J. C. Hopkins (Toronto, 1895).

THOMPSON, LAUNT (1833–1894), American sculptor, was born at Abbeyleix, Ireland, on Feb 8, 1833 In 1847 he emigrated to the United States and settled with his mother at Albany, New York After studying anatomy in the office of a physician, Dr. Armsby, he spent nine years in the studio of the sculptor, E. D. Palmer. In 1857 he opened a studio in New York, and in 1862 became a national academician. He visited Rome in 1868–69, and from 1875–87 was again in Italy, living for most of the time at Florence. He died at Middleton (N.Y.) on Sept. 26, 1894 Among his important works are· "Napoleon the First," at the Metropolitan Museum of Art, New York; "Abraham Pierson," first president of Yale university, New Haven (Conn); an equestrian statue of Gen A E Burnside, Providence (R I); "General Winfield Scott," Soldiers' Home, Washington (D C); "Admiral S F Du Pont," Washington (D C); "General John Sedgwick," West Point (N Y).

THOMSEN, HANS PETER JÖRGEN JULIUS (1826–1909), Danish chemist, was born in Copenhagen on Feb 16, 1826, and spent his life in that city. From 1847 to 1856 he was engaged in teaching chemistry at the Polytechnique, of which from 1883 to 1892 he acted as director, and from 1856 to 1866 he was on the staff of the military high school In 1866 he was appointed professor of chemistry at the university, and retained that chair until 1891 He was awarded the Davy medal in 1883 and elected a foreign member of the Royal Society in 1902. He died on Feb 13, 1909.

His name is famous for his researches in thermochemistry, a subject to which he was attracted as early as 1852, as his first published paper, entitled "Contributions to a thermochemical system," shows But his comprehensive work in this subject was not started until some years later; the results first appeared in 1869, and were published from time to time until 1882. They were collected in *Thermochemische Untersuchungen* (Leipzig, 1882–88; 4 vols), and a summary in Danish, entitled *Thermokemisker Resultater* appeared in 1905; the latter was translated into English as *Thermochemistry* by Miss K. A. Burke.

In the course of his thermochemical work Thomsen made about 3,500 calorimetric measurements and he determined the heat evolved or absorbed in a very large number of chemical reactions Incidentally he verified Kirchoff's equation connecting the change of heat of a reaction with temperature and the specific heats of the reactants and resultants, and also used his measurements to confirm Guldberg and Waage's theory of mass action (1867). Thomsen introduced the term "avidity" to indicate the tendency of an acid to unite with a base and used his results to draw up the first table of relative strengths of acids. He also worked on selenic acid, platinum compounds and hydrogen peroxide, and made accurate determinations of the atomic weights of oxygen and aluminium. In 1853 Thomsen had devised a process for manufacturing soda from cryolite, and this was first worked on a large scale in 1857; the process proved quite successful.

See obituary notice, *Proceedings of the Royal Society* (1910–11).

THOMSEN, VILHELM LUDVIG PETER (1842–1927), Danish philologist, was born on Jan. 25, 1842, at Copenhagen He took his doctor's degree in 1869 and in 1871 became a lecturer at the University of Copenhagen, where from 1887–1916 he was professor of comparative philology In 1876 he visited England and lectured at Oxford university. Thomsen came to be known as one of the most prominent linguists of modern times, and possessed an extensive and thorough knowledge of the various classes of languages In Romance philology he solved the problem of softened consonants (1856), he was the first to ascertain the palatal law in the phonic system of the Indo-European languages In 1894 he deciphered the Orkhon inscriptions from Mongolia, and made in 1899 important interpretations of Etruscan and Lycian texts In *Turcica* (1916) he treated Ancient Turkic He became president of the Royal Danish Scientific Society in 1909. Thomsen died on May 13, 1927.

His publications include.—*Den gotiske Sprogklasses Indflydelse paa den finske* (1869); *The Relations between Ancient Russia and Scandinavia and the Origin of the Russian State* (1877); *Berøringer mellem de finske og de baltiske Sprog* (1890); *Samlede Afhandlinger* (Christiania, 1919).

THOMSON, SIR CHARLES WYVILLE (1830–1882), Scottish naturalist, director of the scientific staff in the Challenger Expedition, was born at Bonsyde, Linlithgowshire, on March 5, 1830, and was educated at Edinburgh University He held professional appointments at Aberdeen and in Ireland, and finally (1870–79) was professor of natural history at Edinburgh. He died at Bonsyde on March 10, 1882. He will be specially remembered as a student of the biological conditions of the depths of the sea His interest in crinoids was stimulated by the results of the dredgings of Michael Sars (1805–1869) in the deep sea off the Norwegian coasts, and he succeeded, with Dr W B Carpenter, in obtaining the loan of H M S "Lightning" and "Porcupine," for successive deep-sea dredging expeditions in 1868 and 1869 These operations showed that animal life exists in abundance down to depths of 650 fathoms, that all invertebrate groups are represented (largely by Tertiary forms previously believed to be extinct), and, moreover, that deep-sea temperatures are by no means so constant as was supposed, but vary considerably, and indicate an oceanic circulation The results of these expeditions were described in *The Depths of the Sea* (1873). The government realised the value of the work and provided H M S "Challenger" for a circumnavigating expedition Thomson sailed at the end of 1872 as director of the scientific staff, the cruise lasting three years and a half (*See* CHALLENGER EXPEDITION.) On his return he received many academic honours, and was knighted In 1877 he published two volumes (*The Voyage of the Challenger in the Atlantic*) of a preliminary account of the voyage

See obituary notice in *Proc. Soc Edin* (1883); also Thomson and Murray, *Reports of the Voyage of H.M S. "Challenger"* (Edinburgh, 1885).

THOMSON, CHRISTOPHER BIRDWOOD, 1ST BARON, cr. 1924 (1875–), British soldier and statesman, was born on April 13, 1875. Educated at Cheltenham and the Royal Military Academy, Woolwich, he served in the Mashonaland campaign and in the South African War From 1902–05 he was instructor at the military engineering school at Chatham In 1909 he passed on to the Staff College and in 1911 to the War Office. During the World War he served as military attaché and chief of the British military mission in Rumania (1915–16), and in Palestine (1917) and was on the Supreme War Council in 1918. Having attained the rank of brigadier-general, he resigned from the service in 1920 as a protest against Allied intervention in Russia. He joined the Labour party, and accompanied, as military expert, the commissions of enquiry dispatched by that body to Ireland and to the Ruhr; later, he visited Russia In 1922, and again in 1923, he stood for Parliament in the Labour interest, but was unsuccessful. In 1924, he was appointed Air Minister in the first Labour Gov-

ernment, with a seat in the Cabinet, and raised to the peerage. A graceful and effective speaker, Lord Thomson also possesses marked literary gifts and has published various writings including *Old Europe's Suicide* (1922); *Victors and Vanquished* (1924); and *Smaranda* (1926).

THOMSON, ELIHU (1853–), American inventor, was born in Manchester, England, March 29, 1853, but removed to Philadelphia, Pa., with his parents in 1858 He received a public school education and in 1876–80 was professor of chemistry and mechanics at the Central High School in Philadelphia In 1880 he went to New Britain, Conn , as electrician for the American Electric Company and two years later he united with Edward J Houston to found the Thomson-Houston Electric Company in Lynn, Mass. In 1892 a merger took place between this company and the Edison General Electric Company to form the General Electric Company, the largest manufacturer of electrical equipment in the world. Thomson remained as director of the large laboratory in Lynn, renamed after him the Thomson laboratory Thomson made the first important research into the nature of the laws governing the electric arc, disclosing the fact that the resistance of the arc varies inversely with the current He invented and constructed an arc light dynamo with a spherical three-coil armature, and the first with an automatic regulator, which went into commercial use in 1880. He was the first to utilize a magnetic field to move an electric arc, a principle which found many uses, notably in the construction of the magnetic blow-out switches In his notable discovery of the so-called alternating current repulsion phenomena he laid the basis for successful alternating current motors He made the first high-frequency dynamo in 1890 and shortly afterwards the first high frequency transformer, and was a pioneer in the development of other high frequency apparatus. In 1886 he invented the art of electric welding by the incandescent method which was simpler and less expensive than previous methods and applicable to a wider range of metals. He also invented the electric watt-hour meter, while the arc lamp, incandescent lamp, alternator, alternating current transformers, and railway motors found improvement at his hands. He made many contributions to the field of radiology and was the first to make stereoscopic X-ray pictures He has published many articles in scientific journals, holds over 700 patents, and has received the Rumford, John Fritz, Kelvin and Faraday medals as well as other honours

THOMSON, JAMES (1700–1748), English poet, author of *The Seasons,* was born at Ednam, in Roxburghshire, on Sept 11, 1700—the third son and fourth child of Thomas Thomson, minister of that place. About 1701 Thomas Thomson removed to Southdean near Jedburgh Here James was educated at first by Robert Riccaltoun, to whose verses on Winter he owed the idea of his own poem, and then at a school at Jedburgh In 1715 he went to Edinburgh university. He became a divinity student, and it was partly to make a reputation as a preacher that he went to London in March 1725. He had already friends in London in Lady Grizel Baillie, and Duncan Forbes of Culloden, and he was introduced by them to literary society in London, where he supported himself partly by acting as tutor.

The Seasons.—Thomson's *Winter* appeared in March 1726. It was dedicated to Sir Spencer Compton, the Speaker, who rewarded the poet, to his great disgust, with a bare twenty guineas. *Summer* appeared in 1727, dedicated to Bubb Dodington In the same year Thomson published his *Poem to the Memory of Sir Isaac Newton* *Spring* appeared in 1728, published by Andrew Millar. In 1729 he produced *Sophonisba,* a tragedy now only remembered by the line "O Sophonisba, Sophonisba, O," and the parody "O Jemmy Thomson, Jemmy Thomson, O" A poem, anonymous but unquestionably Thomson's, to the memory of Congreve appeared in the same year. In 1730 *Autumn* was first published in a collected edition of *The Seasons* It was dedicated to the Speaker, Onslow. In this year, he accompanied the son of Sir Charles Talbot, solicitor-general, upon his travels. In the course of these he projected his *Liberty* as "a poetical landscape of countries, mixed with moral observations on their government and people" In December 1731 he returned with his pupil to London. His pupil died soon after, and Talbot, who became chancellor, gave Thomson a sinecure in Chancery. The first part of *Liberty* appeared in 1734–35, and it was completed in five parts in 1736. The poem was a failure; its execution did not correspond with its design, in a sense indeed it is a survey of countries and might have anticipated Goldsmith's *Traveller.* The truth is that Thomson's poetical gift was for many years perverted by the zeal of partisanship.

His patron died in February 1737 and he lost his sinecure His tragedy *Agamemnon* appeared in April 1738, not before he had been arrested for a debt of £70, from which, according to a story which has been discredited on quite insufficient grounds, Quin relieved him in the most generous and tactful manner The incident took place probably a little before the production of *Agamemnon,* in which Quin played the leading part The play is of course modelled upon Aeschylus and owes whatever of dignity it possesses to that fact; the part of Cassandra, for instance, retains something of its original force. But most of the other characters exist only for the purpose of political innuendo. Agamemnon is George, absent in Germany; Aegisthus is Walpole, and so on As a result his next tragedy, *Edward and Eleanora,* was banned. This event sufficiently accounts for the poet's next experiment, a preface to Milton's *Areopagitica* He joined Mallet in composing the masque of *Alfred,* represented at Cleveden on the Thames before the prince of Wales, on Aug 1, 1740. There can be little question that "Rule Britannia," a song in this drama, was the production of Thomson The music of the song, as of the whole masque, was composed by Arne. In 1744 Thomson was appointed surveyor-general of the Leeward Islands by Lyttelton with an income of £300 a year; this improved his circumstances considerably, and whilst completing at his leisure *The Castle of Indolence,* he produced *Tancred and Sigismunda* at Drury Lane in 1745

Eventually *The Castle of Indolence,* after a gestation of fifteen years, appeared in May 1748 It is in the Spenserian stanza with the Spenserian archaism, and is the first and last long effort of Thomson in rhyme The great and varied interest of the poem might well rescue it from the neglect into which even *The Seasons* has fallen It was worthy of an age which was fertile in character-sketches, and excels in the lifelike presentation of a noteworthy circle. It is the last work by Thomson which appeared in his lifetime In walking from London to his house at Richmond he became heated and took a boat at Hammersmith; he thus caught a chill and died on Aug. 27, 1748. He was buried in Richmond churchyard His tragedy *Coriolanus* was acted for the first time in January 1749. In itself a feeble performance, it is noteworthy for the prologue which his friend Lyttelton wrote, two lines of which—

> He loved his friends—forgive the gushing tear!
> Alas! I feel I am no actor here—

were recited by Quin with no simulated emotion

Precursor of Romanticism.—It may be questioned whether Thomson himself ever quite realized the distinctive significance of his own achievement in *The Seasons,* or the place which criticism assigns him as the pioneer of a special literary movement and the precursor of Cowper and Wordsworth. His avowed preference was for great and worthy themes of which the world of nature was but one, but fortunately his readers were wiser than himself And though he recalled the minds of his contemporaries from the town to the country, in his feeling for nature, he is a true man of his age, his descriptions are general, and purely objective There is no hint yet of the emotional reactions of the Romantic school. He has many audacities and many felicities of expression, and enriched the vocabulary even of the poets who have disparaged him. Yet it is difficult to believe that he was not the better for that training in refinement of style which he partly owed to Pope

The first collected editions of *The Seasons* bear dates 1730, 1738, 1744, 1746. Lyttelton tampered both with *The Seasons* and with *Liberty* in editions after his friend's death. Among the numerous lives of the poet may be mentioned those by his friend Patrick Murdoch, by Dr Johnson in *Lives of the Poets,* by Sir Harris Nicolas (Ald. ed , 1860), by M. Morel, *James Thomson, sa vie et ses oeuvres* (Paris, 1895), and *James Thomson,* in the English Men of Letters Series, by G C. Macaulay (1908). *See* also Dr. G. Schmeding's *Jacob Thomson, ein vergessener Dichter des achtzehnten Jahrhunderts;* the life prefixed to the Aldine edition of his works in 1897; and an excellent edition of *The Seasons* in the Clarendon Press Series by

J. Logie Robertson. Also A. H. Thompson in *Cambridge History of English Literature,* vol. 10 (1913). (D. C. To.; X)

THOMSON, JAMES (1822–1892), British physicist and engineer, was born in Belfast on Feb. 16, 1822, and, like his younger brother, Lord Kelvin, at an unusually early age began to attend the classes at Glasgow University. He trained for civil engineering but ill-health compelled him to avoid physical exertion. Accordingly, from about 1843, he devoted himself to theoretical work and to mechanical invention. To this period belong his well-known researches in thermodynamics (*q.v.*), which enabled him to predict by the application of Carnot's theorem the variation of the freezing point of a substance with pressure. His results were experimentally verified in the physical laboratories of Glasgow university under Lord Kelvin's direction, and were afterwards applied to give the explanation of regelation. In 1861 he extended them in a paper on crystallization and liquefaction as influenced by stresses tending to change of form in the crystals, and in other studies on the change of state he continued Thomas Andrews's work on the continuity of the liquid and gaseous states of matter, constructing a thermodynamic model in three dimensions to show the relations of pressure, volume and temperature for a substance like carbonic acid (*See* LIQUEFACTION OF GASES)

In 1850 he patented his "vortex water-wheel," and during the next three or four years carried on inquiries into the properties of "whirling fluids," which resulted in improved forms of blowing-fans and water-turbines. (*See* HYDRAULICS) Settling in Belfast in 1851, he was selected to be the resident engineer to the Belfast water commissioners in 1853, and four years later became professor of civil engineering and surveying in Queen's college, Belfast In 1873 he was appointed to the chair of engineering in the university of Glasgow, and retained this position until 1889, when the failure of his eyesight compelled him to resign. He died on May 8, 1892 at Glasgow His contributions to geological science included studies of the parallel roads of Glen Roy and of the prismatic jointing of basalt, as seen at the Giant's Causeway. In 1876 and later years he studied the origin of windings of rivers

THOMSON, JAMES (1834–1882), British poet, best known by his signature "B V.", was born at Port-Glasgow, in Renfrewshire, on Nov. 23, 1834, the eldest child of a mate in the merchant shipping service. His mother was a deeply religious woman of the Irvingite sect. On her death, James, then in his seventh year, was procured admission into the Caledonian Orphan Asylum. In 1850 he entered the model school of the Military Asylum, Chelsea. As assistant army schoolmaster at Ballincollig, near Cork, he encountered the one brief happiness of his life: he fell passionately in love with, and was in turn as ardently loved by, the daughter of the armourer-sergeant of a regiment in the garrison, a girl of very exceptional beauty and cultivated mind. Two years later he suddenly received news of her fatal illness and death The blow prostrated him in mind and body. Henceforth his life was one of gloom, misery and poverty, rarely alleviated

While in Ireland he had made the acquaintance of Charles Bradlaugh, then a soldier stationed at Ballincollig. In 1860 was established the paper with which Bradlaugh was so long identified, the *National Reformer,* in which, among other productions by James Thomson, there appeared (1861) the powerful and sonorous verses "To our Ladies of Death," and (1874) his chief work, the sombre and imaginative *City of Dreadful Night.* In October 1862 Thomson was dismissed the army, in company with other teachers, for some slight breach of discipline. Through Bradlaugh, with whom he lived for some years, he gained employment as a solicitor's clerk. From 1866 to the end of his life, except for two short absences from England, Thomson lived in a single room, first in Pimlico and then in Bloomsbury. He was intemperate in his habits, and made few friends. In 1869 his long poem, "Sunday up the River," appeared in *Fraser's Magazine.* In 1872 Thomson went to the western states of America, as the agent of the shareholders in what he ascertained to be a fraudulent silver mine; and in 1873 he received a commission from the New York *World* to go to Spain as its special correspondent.

On his return to England he continued to write in the *Secularist* and the *National Reformer,* under the initials "B.V."[1] In 1875 he severed his connection with the *National Reformer,* owing to a disagreement with its editor; henceforth his chief source of income (1875–1881) was from the monthly periodical known as *Cope's Tobacco Plant.* Chiefly through the exertions of his friend and admirer, Bertram Dobell, Thomson's best-known book, *The City of Dreadful Night, and other Poems,* was published in April 1880, and at once attracted attention; it was succeeded in the autumn by *Vane's Story, and other Poems,* and in the following year by *Essays and Phantasies.* All his best work was produced between 1855 and 1875 ("The Doom of a City," 1857; "To our Ladies of Death," 1861; *Weddah and Om-el-Bonain,* "The Naked Goddess," 1866–1867; *The City of Dreadful Night,* 1870–1874). He died at University College Hospital, in Gower Street, London, on June 3, 1882, and was buried at Highgate cemetery, in the same grave, in unconsecrated ground, as his friend Austin Holyoake.

To the productions of James Thomson already mentioned may be added the posthumous volume entitled *A Voice from the Nile, and other Poems* (1884), to which was prefixed a memoir by Bertram Dobell. If James Thomson has distinct affinity to any writer it is to De Quincey. The merits of Thomson's poetry are its imaginative power, its sombre intensity, its sonorous music; to these characteristics may be added, in his lighter pieces, a Heine-like admixture of strange gaiety, pathos and caustic irony. The same may be said of his best prose. His faults are a monotony of epithet, the not infrequent use of mere rhetoric and verbiage.

See the *Life,* by H. S. Salt (1905 edition).

THOMSON, JOHN ARTHUR (1861–), British naturalist, was born at East Lothian on July 8, 1861, and was educated at the universities of Edinburgh, Jena and Berlin. He was, for a time, lecturer on zoology and biology at the school of medicine in Edinburgh, and in 1899 he became regius professor of natural history at Aberdeen university. Apart from his purely zoological work, chiefly on alcyonarians, Professor Thomson did much, both by his lectures and his numerous attractive books and writings, to popularise biological science, and he was indefatigable in his efforts to correlate science and religion.

His publications include: *Outlines of Zoology,* 7th ed. (1920); *Introduction to Science* (1911); *The Wonder of Life* (1914); *Secrets of Animal Life* (1919); *The System of Animate Nature,* Gifford Lectures (1920); *Science, Old and New* (1924); *The New Natural History* (1925); *Science and Religion* (1925); *Towards Health* (1927) and many other books and papers on allied subjects.

THOMSON, JOSEPH (1858–1895), Scottish explorer in Africa, was born on Feb. 14, 1858 at Penpont, Dumfriesshire, being the fifth son of William Thomson, originally a working stonemason, who had attained the position of a master builder. In 1868 his father removed to Gatelawbridge, where he rented a farm and a quarry. Joseph Thomson worked in his father's quarry before he went up to Edinburgh University. After completing his course in 1878 he was appointed geologist and naturalist to the Royal Geographical Society's expedition to East Central Africa under Keith Johnston. The latter died at Behobeho, between the coast and the north end of Lake Nyasa, in June 1879, and Thomson then took command. He successfully conducted the expedition across the desolate region of Uhehè and Ubena to the north end of Lake Nyasa, and then by a hitherto unexplored track to Lake Tanganyika, where he investigated the Lukuga outlet. From Tanganyika he started to reach the Congo, but troubles with his carriers, who dreaded the warlike Warua, obliged him to retrace his steps. Going round the south end of Tanganyika he discovered Lake Rukwa, and marched via Tabora to the coast at Bagamoyo, reaching London in August 1880.

About this time the sultan of Zanzibar asked Thomson to report on certain supposed coal-beds on the river Rovuma, but the coal proved to be merely bituminous shale.

For a considerable time the explorer had directed his attention to Masailand, through which ran the shortest route from the sea to the headwaters of the Nile. In 1882 the Royal Geographical Society requested Thomson to report on the practicability of

[1]Bysshe Vanolis: "Bysshe," as the commonly used Christian name of Shelley, Thomson's favourite writer; and "Vanolis," an anagram of Novalis (F. von Hardenberg).

taking a caravan through the Masai country He succeeded in crossing the Njiri desert and exploring the eastern rift-valley. Thence he went with a picked company through Laikipia to Mt. Kenya and Lake Baringo, afterwards traversing the unknown region lying between Baringo and Victoria Nyanza, reached on Dec. 10, 1883.

In 1885 he undertook an expedition to Sokoto for the National African (afterwards the Royal Niger) Company, and obtained the signatures of the sultans of Sokoto and Gando to treaties with which he had been entrusted by the company In 1888 he travelled for pleasure through southern Morocco and explored a portion of the Atlas range

In 1890 he entered the service of the British South Africa Company and starting from Quilimane he traversed the region between lakes Nyasa and Bangweulu and the Zambezi. It was a period of tension between the Portuguese and the British, and Thomson's party on leaving the Portuguese frontier was fired on by the Portuguese who, too late, realized that they had allowed a treaty-making envoy to pass through their territory in the guise of a peaceful trader. Thomson concluded treaties with native potentates which gave to the chartered company political, trading and mining rights over a large part of the district since known as North-East Rhodesia. This journey, in which he covered nearly a thousand miles of hitherto unexplored country, proved disastrous to his constitution. In 1893 he visited South Africa in search of health, but unavailingly. He died in London on Aug. 2, 1895. The accounts of his travels not recorded in the books mentioned were published in magazines or in the *Proceedings of the Royal Geographical Society.* Thomson was the last, as he was one of the most successful, of the great geographical pioneers in Africa. He had an extraordinarily keen topographical instinct which enabled him to comprehend at a glance the natural features of the countries he traversed. To undaunted courage and promptness of decision he added a forbearing and patient disposition.

Thomson wrote accounts of his travels under the titles *To the Central African Lakes and Back* (1881), *Through Masailand* (1884), *Travels in the Atlas and Southern Morocco* (1889), also some articles in the *Proceedings of the Royal Geographical Society* He also wrote, in collaboration with Miss E Harris Smith, *Ulu* (1888), a novel based on his insight into the working of the African mind, *Mungo Park and the Niger* (1890), a sound critical biography and many magazine articles on African politics.

See *Joseph Thomson, African Explorer* (1896), a biography by his brother, the Rev. J. B. Thomson, which contains a list of the published writings of the explorer

THOMSON, SIR JOSEPH JOHN (1856–), British physicist, was born on Dec. 18, 1856 near Manchester, and educated at Owens college, Manchester, and at Trinity college, Cambridge, where he was elected a fellow in 1880 and became lecturer in physics in 1883. In 1884 he was appointed Cavendish professor in the University of Cambridge and in 1919 research professor, holding in addition from 1905–18, the professorship of physics at the Royal Institution, London, and subsequently an honorary appointment. He became master of Trinity college in 1918. He developed at Cambridge a great research laboratory, which attracted workers from many countries, and carried out there epoch-making investigations on the conduction of electricity through gases, the determination of the charge and mass of the electron, and analysis by means of positive rays. He became F R S. in 1884, and was president in 1915 He was knighted in 1908, and was the recipient of many awards and honours During the World War he assisted various Government departments in an advisory capacity (*See* GASES)

In addition to a large number of publications in the *Proceedings of the Royal Society* and *The Philosophical Magazine*, he published *A Treatise on the Motion of Vortex Rings* (1883), *The Application of Dynamics to Physics and Chemistry* (1888); *Recent Researches in Electricity and Magnetism* (1893); *Elements of the Mathematical Theory of Electricity and Magnetism* (1895, 5th ed 1921); *The Discharge of Electricity Through Gases* (1898); *The Conduction of Electricity Through Gases* (1903); *Rays of Positive Electricity and Their Application to Chemical Analysis* (1913, 2nd ed, 1922); *The Electron in Chemistry,* five lectures delivered at the Franklin Institute, Philadelphia (1923); and, with Professor Poynting, a number of general text-books on physics.

THOMSON, THOMAS (1773–1852), Scottish chemist, was born at Crieff, Perthshire, on April 12, 1773. He was educated at the universities of St. Andrews and Edinburgh, and after taking the degree of M.D. at the latter place in 1799 established himself there as a teacher of chemistry. From 1796 to 1800 he was connected with the *Encyclopædia Britannica,* and the chemical and mineralogical articles which he contributed to the supplement to the third edition formed the basis of his *System of Chemistry* (1st ed. 1802; 7th ed. 1831) The third edition (1807) is noteworthy as containing the first detailed account of the atomic theory, communicated to him by John Dalton himself. (*See* CHEMISTRY: *History*; ATOMIC WEIGHTS.) In 1813 he began to edit in London the *Annals of Philosophy,* later *Philosophical Magazine* In 1817 he became lecturer in chemistry at Glasgow university, and in the following year was appointed to the regius professorship This chair he retained until his death (July 2, 1852), at Kilmun, Argyleshire. Thomson was a most energetic professor and founded the first chemical laboratory for students in Great Britain He did much to spread a knowledge of Dalton's atomic theory. In addition to various text-books he published a *History of Chemistry* (1830–1831).

THONGA, a group of Bantu-speaking peoples inhabiting the southern half of Portuguese East Africa and the neighbouring regions. It comprises a number of independent tribes, each governed by a chief assisted by councillors. The people live in small household groups, which are scattered irregularly over the tribal territory They keep cattle and goats, and also raise crops of millet and maize They are organized into exogamous patrilineal clans, and have a classificatory system of relationship. Marriage is polygamous, and involves the payment of a bride-price Their religion is mainly ancestor-worship

See H A. Junod, *The Life of a South African Tribe* (1927).

THOR, one of the chief deities of the heathen Scandinavians, is represented as a middle-aged man of enormous strength, an implacable foe to the harmful race of giants (demons), but benevolent towards mankind. His figure is somewhat secondary to that of Odin, represented as his father. But in Iceland and indeed, perhaps, in all northern countries except among the royal families, he was apparently worshipped more than any other god There is evidence that a corresponding deity named Thunor or Thonar was worshipped in England and on the Continent, but little is known about him beyond his identification with the Roman Jupiter His name is the Teutonic word for thunder Outside the Teutonic area he has close affinities with Jupiter or Zeus, and still more with the Lithuanian god Perkunas, whose name (which likewise means "thunder") appears to be connected with that of Thor's mother (Fiörgyn)

See H Petersen, *Om Nordboern es Gudedyrkelse og Gudetro i Hedenold* (Copenhagen, 1876) For other references *see* TEUTONIC PEOPLES. *Religion* (*ad fin*). (H. M. C)

THORAX, the anatomical term for the chest, that part of the body which contains the heart and lungs (*see* ANATOMY: *Superficial and Artistic,* and SKELETON. *Axial*). For the surgery of the thorax reference may be made to the heading HEART AND LUNG, SURGERY OF.

THORBECKE, JAN RUDOLF (1798–1872), Dutch statesman, was born at Zwolle, in the province of Overijssel, on Jan. 14, 1798. He studied at Leyden, and, on the completion of his course, visited the principal German universities. At Giessen he lectured as an extraordinary professor, and at Göttingen, in 1824, published his treatise, *Ueber das Wesen der Geschichte.* After his return to Amsterdam in 1824 Thorbecke wrote his *Bedenkingen aangaande het Recht en den Staat* ("Objections anent Law and the State"), which procured him in 1825 a chair as professor in Ghent university. The Belgian revolt of that year drove him from Ghent to Leyden, where he became professor of jurisprudence and political science His standard work, *Aanteekeningen op de Grondwet* ("Annotations on the Constitution," 1839; 2nd ed., Amsterdam, 1841–43), became the textbook and the groundwork for the new reform party in Holland, as whose leader Thorbecke was definitely recognized. Thorbecke's political career until his death, which occurred at The Hague on June 4, 1872, is sketched under HOLLAND: *History.*

See biographies by Buys (Tiel, 1876) and J A. Levy (The Hague, 1876). There are two collections of his *Speeches* (6 vols., 1867–70, Deventer; and Gronnigen, 1900). His *Correspondence with Groen van Prinsterer* appeared in 1873.

THOREAU, HENRY DAVID (1817–1862), American recluse, naturalist and writer, was born at Concord (Mass), July 12, 1817. To Thoreau this Concord country contained all of beauty and even grandeur that was necessary to the worshipper of nature; he once journeyed to Canada; he went west on one occasion; he sailed and explored a few rivers; for the rest, he haunted Concord and its neighbourhood as faithfully as the stork its ancestral nest

As a boy, Henry drove his mother's cow to the pastures, and thus early became enamoured of certain aspects of nature and of certain delights of solitude At school and at Harvard University he in nowise distinguished himself, though he was an intelligently receptive student and read widely He was, however, proficient enough in Greek, Latin, and the more general acquirements to enable him to act for a time as a teacher But long before this he had become apprenticed to the learning of nature: when only 12 he had made collections for Agassiz, who had then just arrived in America. Thoreau gave up teaching and became a lecturer and author, though it was the labour of his hands which mainly supported him through many years: professionally he was a surveyor.

He had arrived at the conviction that the less labour a man did, over and above the positive demands of necessity, the better for him and for the community at large; he would have had the order of the week reversed—six days of rest for one of labour In 1845 he made the famous experiment of Walden Desirous of proving to himself and others that man could be as independent of his kind as the nest-building bird, Thoreau retired to a hut of his own construction on the pine slope over against the shores of Walden pond —a hut which he built, furnished and kept in order entirely by the labour of his own hands During his two years in Walden woods he lived by the exercise of a little surveying, a little job-work and the tillage of a few acres of ground which produced him his beans and potatoes He read considerably, wrote abundantly, thought actively if not widely, and came to know beasts, birds and fishes with an intimacy more extraordinary than was the case with St. Francis of Assisi. Birds came at his call, and forgot their hereditary fear of man; beasts lipped and caressed him; the very fish in lake and stream would glide, unfearful, between his hands. His *Walden* (1854), the record of this fascinating two years' experience, must always remain a production of great interest.

Some years before Thoreau took to Walden woods he made the chief friendship of his life, that with Emerson He became one of the famous circle of the transcendentalists, always keenly preserving his own individuality amongst such more or less potent natures as Emerson, Hawthorne and Margaret Fuller. From Emerson he gained more than from any man, alive or dead; and, though the older philosopher both enjoyed and learned from the association with the younger, it cannot be said that the gain was equal There was nothing electrical in Thoreau's intercourse with his fellow men; although he absorbed intensely he gave off no spiritual sparks. With children he was affectionate and gentle, with old people and strangers considerate He loved his kind as animals. but did not seem to find them as interesting as those furred and feathered In 1847 Thoreau left Walden lake abruptly, and for a time occupied himself with lead-pencil making, the parental trade. He never married, thus further fulfilling his policy of what one of his essayist-biographers has termed "indulgence in fine renouncements." At the comparatively early age of 45 he died, May 6, 1862. His grave is in the Sleepy Hollow cemetery at Concord.

Thoreau's fame will rest on *Walden; or, Life in the Woods* (Boston, 1854) and the *Excursions* (Boston, 1863), though he wrote nothing which is not deserving of notice. Up to his 30th year he dabbled in verse, but he had little ear for metrical music, and he lacked the spiritual impulsiveness of the true poet His weakness as a philosopher is his tendency to base the laws of the universe on the experience-born, thought-produced convictions of one man—himself. His weakness as a writer is the too frequent striving after antithesis and paradox If he had had all his own originality without the itch of appearing original, he would have made his fascination irresistible. As it is, Thoreau holds a unique place. He was a naturalist, but absolutely devoid of the pedantry of science; a keen observer, but no retailer of disjointed facts. He thus holds sway over two domains: he had the adherence of the lovers of fact and of the children of fancy. He must always be read, whether lovingly or interestedly, for he has all the variable charm, the strange saturninity, the contradictions, austerities and delightful surprises of Nature herself.

The standard editions of his works are *The Writings of Henry David Thoreau*, Riverside ed (11 vol., Boston, 1894–95), and Manuscript ed. (12 vol, 1907).

Thoreau* (Boston, 1908), *The Heart of Thoreau's Journals* (ed by Odell Shephard, Boston, 1927); Brooks Atkinson, *Henry Thoreau, The Cosmic Yankee* (1927). (W. S.; X)

THORFINN KARLSEFNI or Karlsefne (*fl.* 1002–1007), Scandinavian explorer, leader of the chief mediaeval expedition for American colonization. Thorfinn belonged to a leading Icelandic family In 1002 he came to Greenland, married Gudrid, widow of Red Eric's son Thorstein, and put himself at the head of a great expedition now undertaken from Ericsfiord for the further exploration and settlement of the western Vinland (south Nova Scotia?) lately discovered by Leif Ericsson (*q v.*). Three vessels took part in the venture, with 160 men and some women, including Gudrid, and Freydis, a natural daughter of Red Eric They first sailed north-west to the Vesterbygd or "Western Settlement" of Greenland, thence to Bear island, and thence away to the south till they reached a country they named *Helluland* (some part of Labrador?) from its great flat slabs of stone (*hellur*). Two days' sail farther southward brought them to a thickly-wooded land they called *Markland* (*i e*, Woodland, our Newfoundland?). Two days after this they sighted land to the right hand, and came to a cape, where they found the keel of a ship—perhaps a relic of some earlier, possibly Scandinavian explorer—and which they called therefore *Kialarnes* (Keelness; Cape Breton, or some adjacent point?); the long bleak sandy shores of this coast they called the *Wonderstrands* (on the east coast of Cape Breton island?). After passing the *Wonderstrands* and reaching a coast indented with bays, Thorfinn put two fleet Gael runners ashore, with orders to explore southwards (*see* Leif Ericsson); they returned with grapes and wild wheat, proofs that the Northmen were not far from Vinland

The fleet now stood in to a bay called by the explorers *Streamfiord* or Firth of Currents, and wintered there (1003–04), suffering some privations, and apparently getting no more news of the fruitful country desired. Thorfinn's son Snorri was born this first autumn in the new world. Next spring nine of the party, headed by the chief malcontent Thorhall, Red Eric's huntsman, sailed off northward, intending to come to Vinland by rounding Keelness and thence working round west (and south) Adverse weather drove them to Ireland, where they were enslaved. Meanwhile Thorfinn, with the rest of the venturers, sailed south "for a long time," till they reached a spot they called *Hop*, at the mouth of a river which flows from a lake into the sea.

Here they found the "self-sown" wheatfields and vines of Leif's Vinland, and here accordingly they settled and built their huts above the lake (1004–05). After a fortnight natives, swarthy and ill-looking, with ugly hair, great eyes and broad cheeks (Beothuk or Micmac Indians?) appeared with many skin canoes; in the spring following these *Skraelings* came back and bartered with their visitors. Terrified by a bull belonging to the latter they fled, and after three weeks returned to fight They were beaten off, but two of the Northmen were slain The colony at Hop was therefore abandoned and the whole force returned to Streamfiord Thence Thorfinn revisited Hop, staying two months; and also made a voyage northward in search of Thorhall, rounding Keelness and sailing westward (along the north coast of Cape Breton island?), and apparently southward also, till they came to the

mouth of a river flowing from east to west. Here Thorvald Ericsson was killed by a (Skraeling?) arrow, and the expedition came back to Streamfiord where they passed the next winter (1005–06).

Internal dissensions now broke out, mainly about the women of the colony, and in the next summer (1006) the entire project of Vinland settlement was abandoned and the fleet sailed to Markland. Two Skraeling children were captured here and the expedition divided, Thorfinn making Greenland and Ericsfiord in safety with his own vessel, while the other was lost in the Irish sea, only half the crew escaping to Ireland in the ship's boat. (C R B)

On *Flatey Book, Red Eric Saga* and the whole bibliography for the Vinland voyages, including that of Thorfinn, *see* LEIF ERICSSON and VINLAND The six Vinland voyages of *Flatey,* we may repeat, *Red Eric* reduces to three, wholly omitting the alleged voyage of Biarni Heriulfsson, and grouping those of Thorvald Ericsson and Freydis with Thorfinn Karlsefni's in one great colonizing venture.

THORIANITE, a rare mineral found in the gem-gravels of Ceylon as small, heavy, black, cubic crystals, usually much water-worn It was so named on account of its high percentage of thorium (59–79% ThO_2); it also contains the oxides of uranium (11–33%), and the formula $(Th,U)O_2$ is similar to that of uraninite, but with thorium predominating over uranium. Helium is present, and the mineral is slightly less radio-active than pitchblende. A few isolated crystals of the mineral have been found in Transbaikalia, Siberia and in Madagascar Thorianite contains a higher percentage of thoria than any other known mineral, and it has been employed to a limited extent as a source of thoria for use in incandescent gas-mantles.

THORITE, a rare mineral consisting of thorium silicate, crystallizing in the tetragonal system and isomorphous with zircon. The theoretical formula, $ThSiO_4$, requires 81·5% of thoria, but analyses show only 50–70%, there being also some uranium, cerium, etc. The mineral is almost always altered by hydration and is then optically isotropic and amorphous Owing to differences in composition and to alteration, the specific gravity varies from 4·4 to 5·4. The colour is usually light brown, but in the variety known as "orangite" it is orange-yellow. The mineral occurs as isolated crystals and small masses in the augite-syenite near Brevik in south Norway, also at Arendal, and in the gem-gravels of Ceylon If found in larger amount it would be an important source of thoria for incandescent gas-mantles. (L. J. S.)

THORIUM, a chemical element belonging to a group of metals contained in the oxides known as the rare earths (symbol Th, atomic number 90, atomic weight 232 2). In 1828, Berzelius gave the name thoria (after the god, Thor) to the basic oxide extracted from the thorite of Lovön (Norway). Thorium is present as the main constituent in thorite and orangite, which are thorium silicates, $ThSiO_4$, auerlite, calciothorite, freyalite, mackintoshite and thorianite (ThO_2, 60–78%, with oxides of uranium), but the only commercial source is monazite sand, a complex phosphate of the rare (cerite) earths containing 2 to 10% of thoria. This sand is found in Brazil, Travancore, North and South Carolina, Idaho, Australia and the Malay Archipelago The first two sources are the most important commercially, the Travancore deposits furnishing three-fourths of the world's supply Thoria is extensively used in the construction of incandescent gas mantles (*see* LIGHTING AND ARTIFICIAL ILLUMINATION) this being the main industrial application of thorium.

Metallic Thorium.—Owing to its intense chemical reactivity towards hydrogen, nitrogen, oxygen, carbon and the metals, thorium is isolated only with considerable difficulty. Anhydrous thorium chloride when heated with sodium *in vacuo* furnishes a pure product. Thorium is also obtained (i) by passing the vapour of its iodide over heated tungsten filaments, (ii.) by the action of calcium on thoria, (iii) by passing thorium acetylacetone and sodium vapours through a red hot tube It is a leaden-grey metal of specific gravity 12·16, resembling platinum in hardness and ductility. Its melting point is 1,845° C. Thorium ribbon when heated to red heat continues to burn in air, giving a shower of sparks. At 450° C the metal combines with the halogens and with sulphur, and at 650° C with hydrogen and nitrogen. Thorium is dissolved by strong hydrochloric acid or aqua regia but other acids attack it only slowly. It is not affected by alkalis but alloys with aluminium, copper and nickel; the thorium-tungsten alloy is of industrial use for making filaments for incandescent electric lamps. Tungsten containing 0·5 to 10% of thorium, when used as the cathode of an electric discharge apparatus, gives at 1,030° C an electron emission equal to that furnished by pure tungsten at 1,700° C. Thorium is strongly radioactive.

Extraction of Thoria.—Thorite and thorianite are dissolved in mineral acid and the solution evaporated down to render silica insoluble. Ammonium sulphide is added to the aqueous extract to precipitate such common metals as iron and lead. The thoria remaining in solution is separated through its carbonate, sulphate or oxalate.

Monazite is broken up with strong sulphuric acid, the solution diluted and partially neutralised with alkali (ammonia, caustic soda or magnesia), when thorium phosphate is precipitated. This phosphate is dissolved in hydrochloric or sulphuric acid and the thorium reprecipitated as oxalate. Further purification may be effected by means of (i) thorium carbonate, which is more soluble than other rare-earth carbonates in sodium carbonate; (ii) ammonium thorium oxalate which is soluble; or (iii.) fractional crystallisation of thorium sulphate, $Th(SO_4)_2,8H_2O$ Finally, the purified thoria is converted into thorium nitrate, the salt employed in the mantle industry The world's annual consumption of monazite is about 3,000 tons, and of this, 200 tons are worked up in Great Britain, ilmenite (*see* TITANIUM) and mesothorium being useful by-products Each kilogram of monazite on acid treatment evolves one litre of helium, also obtainable by heating the mineral to redness.

Gas Mantles.—Incandescent mantles are manufactured by impregnating a woven stocking of combustible fabric (cotton or ramie) with the nitrates of thorium and cerium The impregnated stocking is ignited to convert these nitrates into oxides, the mixture of nitrates being adjusted so that the mixed oxides consist of 99% of thoria, and 1% of ceria, this mixture giving optimum luminosity at comparatively low temperatures About 300 millions of incandescent gas mantles are consumed annually, of which the United States takes approximately 80 millions

Thorium Compounds—Thorium in combination is uniformly quadrivalent. Thoria (thorium dioxide), ThO_2, a white powder of specific gravity 10·20, is obtained by heating thorium salts of volatile acids or by igniting the hydroxide, $Th(OH)_4$, a heavy white powder precipitated by alkali from thorium solutions Thoria is a refractory material utilisable in making cupels and crucibles. Thorium tetrachloride is obtained in colourless prisms melting at 820° C by heating thoria in the vapour of carbon tetrachloride or sulphur chloride. Thorium sulphate, $Th(SO_4)_2$, crystallises with 4, 8 and 9 molecules of water, and the nitrate with 5, 6 and 12 H_2O. Commercial thorium nitrate should contain a minimum of 48% ThO_2.

Thorium acetylacetone, $Th\{CH(CO{\cdot}CH_3)_2\}_4$, a white crystalline product melting at 171° C and soluble in alcohol or chloroform, is distillable *in vacuo* without decomposition. Thorium salts of organic acids have been employed medicinally for skin trouble and in cholera and dysentery on account of their radioactive character Thoria is used as a catalyst in organic syntheses (ketones from acids). Inhalations of thorium emanation (thoron) are stated to be efficacious in diseases of the respiratory organs.

THORN or, better, **TORUN,** a town of Poland, in the province of Pomorze, situated on the right bank of the Vistula, 85 m. by rail N E. of Poznan, and 92 m. S. of Danzig. Pop. (1921), 39,300. Torun has always been an important town owing to its position between Pomerania, Poland Proper and East Prussia, and its strategical importance as a bridge head commanding the passage of the Vistula. The old town and the new town, founded in the 13th century, were united in the 15th, and both retain a number of interesting buildings dating from the 14th, 15th and 16th centuries, when Torun was a flourishing

member of the Hanseatic League. The ruined castle of the Teutonic knights, part of the old walls, the town hall, the churches of St. John, of the Virgin and of St. James, are the most interesting edifices. There is a monument to Kopernik (Copernicus) who was born in Torun. The old wooden bridge has been succeeded by a massive iron railway viaduct 3,300 ft. long. Torun carries on an active trade in grain, timber and foodstuffs, and has ironworks, saw-mills and other manufactures.

Torun was founded in 1231 by the Teutonic Order, which was given land there and invited to help the Poles against the heathen Prussians. It became a subject city of the Order and an important member of the Hanseatic League, but political and commercial interests bound it to Poland. In 1454 the city revolted against the Order and was annexed to Poland in 1466 at the Peace concluded there Religious differences were always strong in Torun, and a riot in 1724, terminating in a brutal execution, made a great stir in Europe. The town was seized by Prussia at the Second Partition, was returned to the Grand Duchy of Warsaw, and again granted, in 1815, to Prussia, in which it remained till 1918

THORN, in botany, a hard pointed structure, also termed a "spine," generally representing a small branch, as in hawthorn, where a normal branch arising in the axil of a leaf is replaced by a sharply pointed thorn, accessory buds on each side of the thorn and developed in the same leaf-axil will grow in the next season into ordinary branches. The similarly developed thorns of the honey-locust (*Gleditschia*) are branched In other cases, as the sloe or the wild pear, branches become spiny at the apex tapering into a stiff leafless point. On a cultivated tree these branches disappear owing to their more vigorous growth. Leaves may be modified into spines, as in barberry, the leaves of which show every gradation between a leaf with a spiny-toothed edge and those which have been reduced to simple or multiple spines. In some species of *Astragalus* the petiole of the pinnately compound leaf persists after the fall of the leaflets as a sharp spine In the false acacia (*Robinia*) the stipules are represented by spines

THORNABY-ON-TEES, a municipal borough in the North Riding of Yorkshire, England, 3 m S.W of Middlesbrough, on the L.N E. railway Pop (1921) 19,826 It lies on the river Tees, opposite Stockton-on-Tees, with which it is connected by a bridge. The town was formerly known as South Stockton and is still included in the parliamentary borough of Stockton, but it was incorporated as a separate municipal borough in 1892. The population is employed in blast furnaces, iron foundries, engineering works, iron ship-building yards, extensive saw-mills, flour-mills and manufactures of "blue and white" pottery.

THORNDIKE, EDWARD LEE (1874–), American psychologist, was born at Williamsburg, Mass., on Aug. 31, 1874 He prepared for college in the Roxbury Latin school. He received the A B. degree in 1896 and the A.M. degree in 1897 from Harvard His first teaching appointment was instructor in Western Reserve in 1898–99, followed by an appointment as instructor in genetic psychology at Teachers college, Columbia university, in 1899 Since that date he has remained at Teachers college and has taken a leading part in the development of that institution, having been promoted to adjunct professor of educational psychology in 1902, and professor in 1904 During the World War Thorndike was chairman of the committee on classification of personnel in the army, and in that capacity was instrumental in establishing an efficient system for the classification and distribution of troops. In 1921 he became director of the division of psychology of the institute of educational research at Teachers college. A recent compilation of his writings shows over 300 titles, more than 30 of which are well known books. Among these are *Mental and Social Measurements* (1904); *Principles of Teaching* (1905); *Elements of Psychology* (1905); *Educational Psychology* (1914); and *Measurement of Intelligence* (1926).

THORNDIKE, SYBIL (1885–), British actress, was born at Gainsborough, Lincolnshire, and educated at the high school, Rochester, when her father, Rev. A. J. W Thorndike, was a canon of the cathedral. From 1903–07 she toured America in Shakespearian repertory with Ben Greet. Returning to England she became a member of Miss Horniman's company at the Gaiety theatre, Manchester, 1908–09. In 1914, she became attached to the "Old Vic" company in London. She remained there until 1918, and acted in many principal Shakespearian parts. In 1919 she appeared in a series of matinées at the Holborn Empire, in which she played the parts of Hecuba in *The Trojan Women* and of Candida, in Bernard Shaw's play of that name. Henceforward her success was assured. Among her principal parts were those of Jane Clegg in St. John Ervine's play, and Joan of Arc in Bernard Shaw's *Saint Joan.* From 1920–22 she sustained a number of leading parts in Grand Guignol at the Little theatre, London In 1908 Miss Thorndike married Lewis Thomas Casson

THORNE, a market town in the West Riding of Yorkshire, England, 10 m. N E of Doncaster, by the L N E. railway. Pop (1921) 6,076. It lies near the right bank of the river Don, in a low, flat district, which was formerly a marshy waste. Hatfield Chase, a portion of this tract south of Thorne, was partly drained by the Dutch engineer Vermuyden in the 17th century and there were in the district numerous Dutch settlers. To-day "the levels," as the surrounding district is generally named, is drained by numerous canals, and the town has a water communication with Goole and the Humber This latter fact, together with the remarkable fertility of "the levels," contributes to the importance of Thorne as an agricultural centre and market town.

Hatfield Chase is generally considered to have been the scene of the battle of Heathfield in 633, when King Edwin of Northumbria fell before the heathen King Penda of Mercia.

THORNHILL, SIR JAMES (1676–1734), knighted 1715, English historical painter, was born at Melcombe Regis, Dorset He obtained the patronage of Queen Anne, and was in 1719–20 appointed her serjeant-painter in succession to Highmore The queen ordered him to decorate the interior of the dome of St Paul's with a series of eight designs, in chiaroscuro heightened with gold, illustrative of the life of the apostle. He also designed and decorated the saloon and hall of Moor Park, Herts, and painted the great hall at Blenheim, the princesses' apartments at Hampton Court, the hall and staircase of the South Sea Company, the chapel at Wimpole, the staircase at Easton-Neston, Northamptonshire, and the hall at Greenwich hospital, usually considered his most important and successful work, upon which he was engaged from 1708 to 1727 Among his easel pictures are the altar-pieces of All Souls and Queen's college chapels, Oxford, and that in Melcombe Regis church, the portrait of Isaac Newton, in Trinity college, Cambridge, and the picture of the House of Commons in 1730, in which he was assisted by Hogarth, who married Jane, his only daughter. He executed careful full-size copies of Raphael's cartoons, which now belong to the Royal Academy About 1724 he opened a drawing-school in his house in Covent Garden. He died on May 4, 1734

THORNHILL, an urban district in the West Riding of Yorkshire, England, 2 m. S of Dewsbury on the L M S railway Pop. (1921) 11,722 The church of St. Michael has a modern nave, but the chancel with aisles is of good Decorated work, and the tower is Perpendicular The east window contains fine fragments of stained glass of the 15th century The large industrial population is employed in the woollen mills and manufactures of shoddy and carpets.

THORNHILL, village of the parish of Morton, Nithsdale, Dumfriesshire, Scotland, 14 m. N.N W. of Dumfries by the L.M.S. railway Pop. (1921), 1,577. It lies among tree-clad hills and is watered by the Nith and such streams as the Carron, Cample and Crichope Morton parish church lies in the village. There is a natural history museum with a statue of Richard Cameron, the covenanter (1680) in the grounds There are weekly sales of livestock, and an agricultural show is held every September. Near the town are freestone quarries, and a bacon factory. Three miles N N.W. stands Drumlanrig castle, a seat of the duke of Buccleuch, begun in 1679. The fourth duke of Queensberry, "Old Q," incurred the wrath of Robert Burns and Wordsworth by his wanton destruction of the magnificent woods. On the death of "Old Q" without issue in 1810, Henry, third duke of Buccleuch, succeeded to the dukedom of Queensberry, and the property has since been adequately cared for. The gardens and park are very fine. The

ruins of Tibber's castle, dismantled in 1311 by Robert Bruce, stand in the grounds, about 1 m. from the mansion

THORNYCROFT, SIR JOHN ISAAC (1843–1928), British naval architect, brother of Sir Hamo Thornycroft (*q v.*), was born in Rome, on Feb 1, 1843, and educated privately and at Glasgow university In 1866 he established shipbuilding works at Chiswick, which later became known for the production of high-speed launches and torpedo craft In his yards was built the first British naval torpedo-boat, the "Lightning" (1877). The growing size of the torpedo-boats necessitated the removal of the works to Woolston, Southampton, in 1906 In 1916 Thornycroft built a large number of high-speed torpedo boats, constructed to skim the water, which proved very successful. He was elected F R.S. in 1893, and was knighted in 1902. He died on June 28, 1928, at Bembridge, Isle of Wight

THORNYCROFT, SIR WILLIAM HAMO (1850–1925), British sculptor He assisted his father, Thomas Thornycroft in carrying out the fountain in Park lane, London, and modelled the figures of Shakespeare, Fame and Clio, in 1871 In 1872 he exhibited at the Royal Academy, "Professor Sharpley" in marble, for the memorial in University college His "Warrior Bearing a Wounded Youth from the Field of Battle" gained the gold medal at the Royal Academy schools in 1875 In this and in "Lot's Wife" in marble (1878) and "Artemis" (1880) Thornycroft turned towards the Greek school In 1880 he was elected A R A, and R A in 1888. He was awarded a medal of honour at the Paris exhibition in 1900 He was knighted in 1917, and died in 1925

Thornycroft's sculptures include "The Mower" (1884), "Teucer" (1881), a bronze figure now in the Tate gallery, London; statues of "General Charles Gordon" (1885), in Trafalgar square, "Oliver Cromwell," at Westminster (1899), and the "Gladstone Monument," in the Strand, London. *See* M. H. Spielmann, *British Sculpture and Sculptors of To-day.*

THÓRODDSEN, THORVALDUR (1855–1921), Icelandic geographer, was born on the island of Flatey, in Breidifjördr, Iceland, on June 6, 1855, the son of Jón Thóroddsen. He was educated at Reykjavik and at the university of Copenhagen, where he studied natural science and geography In 1876 he was sent to Iceland by the Danish government with Professor Johnstrup to investigate the causes of the eruption which had occurred in 1875 at Askja in Dyngjufjoll, and this was the beginning of a long series of Icelandic explorations In 1880 he was appointed master at the school of Modruvellir in northern Iceland, and in 1882–84 made extensive explorations into the interior He travelled in England and on the Continent from 1884 until 1886 when he was appointed schoolmaster at Reykjavik Until 1898 he made a journey of exploration nearly every year, the later expeditions being undertaken from Copenhagen, where he settled in 1895

His works include several volumes on the Volcanoes of Iceland, the last being *Die Geschichte der isländischen Vulkane* (1925); other works are *Land fraedissaga Island* (1892); *Geschichte der islandischen Geographie* (2 vols, 1898); and *Island Grundriss der Geographie and Geologie* (1905).

THORPE, SIR THOMAS EDWARD (1845–1925), British chemist, was born at Harpurhey, Manchester, on Dec. 8, 1845; he studied at Owen's college and then under Bunsen at Heidelberg. In 1870 he became professor of chemistry at Anderson's college, Glasgow, and four years later at the Yorkshire college, Leeds In 1885 he obtained the chair at the Normal School of Science (now the Imperial College of Science), London, and remained there until appointed director of the Government laboratories in 1894 On his retirement, in 1909, he returned to the Imperial college for a period of three years. He was elected to the Royal Society in 1876, was made a C.B. in 1900 and knighted in 1909. He died on Feb. 23, 1925.

Thorpe is perhaps best known for his work as an organizer in connection with the Government laboratories, and as a brilliant lecturer and writer His *Essays in Historical Chemistry* is an attractive and interesting work. He also brought out, with the co-operation of a number of specialists, the well-known *Dictionary of Applied Chemistry*, a new edition of which was completed in 1927 (1st ed, 1890). His contributions to chemical knowledge include a very accurate series of measurements of the specific volumes of chemical substances of related composition. With A.E.H. Tutton, he studied the oxides of phosphorous (*q.v.*) (1886 *et seq.*); they discovered P_2O_4 and investigated this and P_4O_6. From 1884 to 1886 he made a long series of measurements (with J. W. Rodger) of the viscosities of organic substances, and attempted to correlate fluidity and composition. With Sir A. Rucker, he carried out a magnetic survey of the British Isles. See *Proc. Roy. Soc.* (1925).

THORWALDSEN, BERTEL (1770–1844), Danish sculptor, the son of an Icelander who had settled in Denmark, and there carried on the trade of a wood-carver, was born in Copenhagen on Nov. 19, 1770. He entered the Copenhagen school of art, and in 1792 won the highest prize, the travelling studentship. In 1797 he went to Rome, where Canova was at the height of his popularity. Thorwaldsen's first success was the model for a statue of Jason, highly praised by Canova, which he was commissioned to execute in marble by Thomas Hope, a wealthy English art-patron. From that time Thorwaldsen's success was assured, and he did not leave Italy for twenty-three years. In 1819 he returned to Denmark, where he was commissioned to make the colossal series of statues of Christ and the twelve apostles which are now in the Fruenkirche in Copenhagen These were executed after his return to Rome, and were not completed till 1838, when Thorwaldsen again returned to Denmark He died suddenly on March 24, 1844, bequeathing a great part of his fortune for the building and endowment of a museum in Copenhagen. His collection of works of art and the models for all his sculpture went to furnish the museum, in the courtyard of which he is buried under a bed of roses, by his own special wish.

On the whole Thorwaldsen was the most successful of all the imitators of classical sculpture, and many of his statues of pagan deities are modelled with much of the antique feeling for breadth and purity of design. For Christian sculpture he had no real feeling, and the tomb of Pius VII. in St. Peter's and the "Christ and Apostles" at Copenhagen are less successful Thorwaldsen worked sometimes with feverish eagerness; at other times he was idle for many months together A great number of his best works exist in private collections in England

See Eugène Plon, *Thorwaldsen, sa vie,* etc. (Paris, 1880); Andersen, *B Thorwaldsen* (Berlin, 1845); Killerup, *Thorwaldsen's Arbeiten,* etc. (Copenhagen, 1852), Thiele, *Thorwaldsen's Leben* (Leipzig, 1852–1856); C A Rosenberg, *Thorwaldsen . mit 146 Abbildungen* (1896, "Künstlermonographien," No. 16), S Trier, *Thorvaldsen* (1903), A Wilde, *Erindringer om Jerichau og Thorvaldsen* (1884); F. Oppermann, *Thorvaldsen, hans Barndom og Ungdom* (1924).

THOTH, the Greek name of the Egyptian god of letters, invention and wisdom, the mouthpiece and recorder of the gods, and arbiter of their disputes. Thoth is found on the earliest monuments symbolized by an ibis (*Ibis aethiopica,* still not uncommon in Nubia), which bird was sacred to him

See E. A. W. Budge, *The Gods of the Egyptians.*

THOU, JACQUES AUGUSTE DE [THUANUS] (1553–1617), French historian, was the grandson of Augustin de Thou, president of the parlement of Paris (d 1544). He studied law at Orleans and at Bourges, where he made the acquaintance of Hotman, and finally at Valence, where he had Cujas for his master and Scaliger as a friend. He was at first intended for the Church; he received the minor orders, and on the appointment of his uncle Nicolas to the episcopate succeeded him as a canon of Notre-Dame As *conseiller d'état* he served faithfully both the effeminate, bigoted and cruel Henry III. and Henry IV, a sceptic and given to love-intrigues, because they were both the representatives of legitimate authority. He succeeded his uncle Augustin as *président à mortier* (1595), and used his new authority in the interests of religious peace, negotiating, on the one hand, the Edict of Nantes with the Protestants, while in the name of the principals of the Gallican Church he opposed the recognition of the Council of Trent This attitude exposed him to the animosity of the League party and of the Holy See, and to their persecution when the first edition of his history appeared.

This history was the work of his whole life. His materials

for writing it were drawn from his rich library, which he established in the Rue des Poitevins in the year 1587, with the two brothers, Pierre and Jacques Dupuy, as librarians. His object was to produce a purely scientific and unbiassed work, and for this reason he wrote it in Latin, giving it as title *Historia sui temporis.* The first 18 books, embracing the period from 1545-1560, appeared in 1604 (1 vol. folio), and the work was at once attacked by those whom the author himself calls *les envieux et les factieux.* The second part, dealing with the first wars of religion (1560–1572), was put on the *Index librorum prohibitorum.*

The third part (up to 1574), and the fourth (up to 1584), which appeared in 1607 and 1608, caused a similar outcry, in spite of de Thou's efforts to remain impartial. In answer to his detractors, he wrote his *Mémoires,* which are a useful complement to the *History of his own Times* After the death of Henry IV., the queen-regent refused him the position of first president of the parlement, appointing him instead as a member of the *Conseil des finances.* He continued to serve under Marie de Medicis, and took part in the negotiations of the treaties concluded at Ste Menehould (1614) and Loudun (1616) He died at Paris on May 7, 1617.

Three years after the death of de Thou, Pierre Dupuy and Nicolas Rigault brought out, with pt. v., the first complete edition of the *Historia sui temporis,* comprising 138 books, they appended to it the *Mémoires,* also given in Latin (1620). A hundred years later, an Englishman, Samuel Buckley, published a critical edition, the material for which had been collected in France itself by Thomas Carte (1733). De Thou's history is a model of exact research, drawn from the best sources, and presented in a style both elegant and animated. The standard translation is *Histoire universelle,* by Le Beau, Le Mascrier, the Abbé Des Fontaines, 1734. The *Mémoires* had already been translated by Le Petit and Des Ifs (1711), in this form they have been reprinted in the collections of Petitot, Michaud and Buchon. To de Thou we also owe certain other works a treatise *De re accipitraria* (1784), a *Life,* in Latin, of Papyre Masson, some *Poemata sacra, etc.*

For his life may be consulted the recollections of him collected by the brothers Dupuy (*Thuana, sive Excerpta J A Thuani per ff P P,* 1669, reprinted in the edition of 1733), and the biographies by J. A. M. Collinson (*The Life of Thuanus,* 1807), and Duntzer, (*De Thou's Leben,* 1837) Finally, *see* Henry Harrisse, *Le Président de Thou et ses descendants, leur célèbre bibliothèque* (1905).

THOUARS (tōō-ar), a town of W France, in the department of Deux-Sèvres, on the right bank of the Thouet, 24 m S by W. of Saumur on the railway to Bordeaux Pop. (1926) 7,419. Thouars, which probably existed in the Gallo-Roman period, became in the 9th century the seat of powerful viscounts, who in later times supported the English In 1372 the latter were expelled from the town by Bertrand du Guesclin. In 1563 Charles IX created Louis III, the head of the family of La Trémoille, duke of Thouars. In 1793 the Vendeans took the town by assault. A massive stronghold built in the early 17th century by the La Trémoille family stands on a rocky hill overlooking the river. The adjoining 16th century Sainte-Chapelle is in the Gothic style with Renaissance details The church of St Médard, rebuilt in the 15th century, has a Romanesque doorway That of St Laon (12th and 15th centuries) was formerly attached to an abbey, the buildings (17th century) of which serve as town-hall Remains of the 13th century ramparts of the town, flanked by huge towers, are still to be seen, and a bridge of the same period crosses the Thouet. The manufacture of shoes, and the preparation of veterinary medicine and lime, are carried on. Wine, live stock and agricultural produce are the chief articles of trade

THOUGHT, LAWS OF. Logicians usually formulate certain ultimate principles or assumptions implied in all consistent thinking and reasoning. These principles are known as the "laws of thought" in the narrower and more usual sense of the expression, though in a wider sense the rules of the syllogism and of induction, etc., might be called laws of thought Three or four such fundamental principles are usually formulated. Perhaps a fifth ought to be added. They are as follows (1) *The Principle of Identity:* "A is A," or "a thing is what it is" or "everything has a certain character which it retains more or less" (*see* IDENTITY). (2) *The Principle of Contradiction:* "A is not non-A," or "A cannot both be B and not be B," or "A cannot be both B and non-B," "a thing cannot both have and not have a certain attribute," or "the same predicate cannot be both affirmed and denied of the same subject." (3) *The Principle of Excluded Middle:* "A either is or is not B," or "A is either B or non-B," or "a thing must either have or not have a certain character," or "of two contradictory predicates one can be asserted of every relevant subject." (4) *The Principle of Sufficient Reason:* "Nothing occurs for which one having sufficient knowledge might not be able to give a reason sufficient to determine why it is as it is and not otherwise" (Leibniz). (5) *The Principle of Uniformity of Reasons:* "Whatever is regarded as a sufficient reason in any one case must be regarded as a sufficient reason in all cases which are essentially of the same kind," or, expressed negatively, "nothing can be regarded as a sufficient reason in any one case unless it can also be regarded as a sufficient reason in all cases of that kind" (A. Wolf)

These principles are indemonstrable assumptions or postulates. If they cannot be proved, neither can they be disproved Any one, who chooses to challenge, say, the principle of contradiction, would only put himself in an absurd position. For, by refusing to accept its validity, he admits the possibility that those who accept it and those who reject it may both be right. So he has nothing to object to. Again, in describing these principles as laws of *thought* it is not intended to contrast thought with things, and to suggest that they are mere peculiarities of human ways of thinking without foundation in objective fact—as Nietzsche and some pragmatists or sceptics would maintain. Normally what we really think we believe to be true of the facts referred to. The laws of thought were originally assumed to hold good of things as well as of thought; and they are still so regarded by many thinkers. *See* LOGIC and the bibliography given there

THOUGHT-READING, the perception of another person's thoughts in the absence, or apparent absence, of normal means of communication (*See* PSYCHICAL RESEARCH.)

THOUGHT TRANSFERENCE: *see* TELEPATHY

THOUSAND AND ONE NIGHTS. In 1704 there appeared at Paris the first four volumes of a collection of Arabic stories called *Les Mille et Une Nuits,* translated by Antoine Galland (1646–1715; *q v*), an orientalist and archaeologist of high reputation in his day, but now remembered chiefly for this translation in which the *Nights* were first introduced to the Western world In 1705 volumes v and vi appeared in 1706 volume vii; in 1709 volume viii, only half of which was by Galland or from the *Nights;* in 1712 volumes ix and x, wholly by Galland; in 1717, two years after Galland's death, volumes xi and xii, from his papers The book had an enormous success pirated editions at once appeared in Holland; there were many European versions made from it At least as early as 1707, six of the volumes were rendered into English by an unknown translator, often called "the Grub Street translator," under a long descriptive title beginning with *Arabian Nights Entertainments* It is safe to say that the *Arabian Nights* of the childhood of all of us was some form or other, complete or incomplete, of a version from Galland's French.

At two points the *Nights* were fortunate in their introduction to Europe First, Galland was a born story-teller and he was able to adapt these Oriental tales not only to the taste of the France of his time but to the universal story-reading public of all countries and times Some of his versions have been rendered back even into Oriental languages and received with favour in the East. It cannot be claimed that he was a faithful translator—no one in his time was—and his recasting belongs more to French than to Arabic literature. But he produced a great French story-book and without his genius it is conceivable that the *Nights* would never have taken the place with us that they have done And, second, fortune placed in his hands excellent materials. He had begun with a translation of Sinbad the Sailor; then he learned that this was only part of a larger collection and there were sent to him from Syria three volumes of a manuscript of the *Nights* which is still the oldest manuscript known and in many respects the best and the most authentic Later, when in his seventh volume he had exhausted the material in this manuscript, fortune again favoured him and introduced him to a Maronite

from Aleppo, named Hanna, brought to France by the traveller Paul Lucas. Hanna related to him in Arabic some of the stories which fill his last four volumes and gave him copies of some of them in writing The Galland version is thus highly composite. Further details on it should be sought in H. Zotenberg's *Histoire d' 'Alâ al-Dîn ou la Lampe Merveilleuse, Texte arabe publié avec une notice sur quelques manuscrits des Mille et une Nuits* (Paris, 1888) In this volume Zotenberg gave the Arabic text of "Aladdin," known until then only in Galland's translation; and in the *Journal of the Royal Asiatic Society* (April 1910; Jan 1913) the present writer gave the only known Arabic text of "Ali Baba and the Forty Thieves," discovered by him in the Bodleian For the place which the Galland manuscript takes among the manuscripts of the *Nights*, reference may be made to an article by the present writer, "A Preliminary Classification of Some Manuscripts of the Arabian Nights" in the *Volume of Oriental Studies* presented to E. G Browne in 1922.

Early History.—But what do we know of the earlier history of this collection of tales? It is unfortunate that the Mohammedan world has never regarded it as belonging to polite literature; it fell rather into the class of recitations in the coffee-house and indicated an uncultivated, almost depraved taste in those who cared for it This has had two results (1) We are thrown back for the history of the collection on stray allusions often difficult to interpret (2) The collection has never been stable but highly fluid, consisting at different times of different stories; it has been subject to the caprice of different redactors who drew upon the vast reservoir of popular tales to fill out the number of a thousand and one nights; and it may be said, in short, that the introductory framework story and the division in consequence into nights are about the only certain features in these different recensions There is thus no such thing as a standard text of the *Nights* which has existed through its long history The text, which seems now to have attained to the dignity of a Vulgate and which is known to all through the translations of Lane, Torrens, Payne, Burton and Littmann, is quite modern. It was compiled in Egypt by an unknown redactor toward the end of our 18th century, as Zotenberg has shown in his *Notice* cited above There are numerous manuscripts of it in existence and all the printed texts are derived from it except two, the edition of the first 200 nights, known as Calcutta I, which is a remote descendant of the Galland manuscript (*see* "Classification" above, pp. 311 ff), and the Breslau edition (Breslau 1826–38) which is a compilation by the editor Habicht from a number of manuscripts including a large section from the Galland manuscript (*see* article in *Journal of Royal Asiatic Society,* July 1909, pp. 635 ff.). Of this modern Egyptian Vulgate the first Būlāq edition (A H. 1252, A D 1835) gives the most trustworthy text. The generally parallel second Calcutta edition (1839–42), also from an Egyptian manuscript, has been contaminated from Calcutta I. and Breslau.

The oldest testimony we have, apart from Indian folk-lore evidence, to the existence of a collection of stories held together by a framework story like that of our *Nights* is in the historical encyclopaedia of Mas'ūdī (d. A H. 345 = A D 956) commonly called "The Golden Meadows." In it (Paris ed iv, pp 89f), speaking of lying stories told by pseudo-traditionalists and by the popular purveyors of edifying legends, he says: "These are like the books transmitted to us and translated for us from the Persian, Indian and Greek, the origin of which was similar to these, such as 'The Book of *hazār afsāna*,' or, translated from Persian to Arabic, 'of a thousand *khurāfas*,' for a *khurāfa* is called in Persian an *afsāna*. The people call this book 'A Thousand Nights and a Night.' " He, then, goes on to give an outline of the framework story which resembles that of our *Nights* but is not quite the same. *Khurāfa* is a rather disrespectful Arabic word for a pleasant and strange but incredible story. The exact usage of it has varied at different times. As to the framework story in its different forms, Cosquin (*Revue Biblique,* January to April, 1909) has shown that a number of similar frames exist in Indian stories. It can be traced definitely back indeed to Indian folklore. Another form of the same passed into North Africa and is the framework story of a collection called *The Hundred and One Nights* (Gaudefroy-Demombynes *Les Cent et Une Nuits*, traduites de l'Arabe, Paris, no date). These folk-lore investigations show that any connections between this story and the Book of Esther and Persian national legends, according to De Goeje's hypothesis in earlier editions of this encyclopaedia, can only have been *en passant* when the story was on its way from the extreme east of Asia to the west of North Africa Cosquin has removed the whole question from literary to folk-lore tradition Further, it is to be observed that there is no evidence that this *Thousand and One Nights* of Mas'ūdī contained any of the stories which are in our manuscripts of the *Nights,* except the framework story.

The next witness to a *Nights* is the *Fihrist,* a *catalogue raisonné* of Arabic literature, compiled between A.H. 377 and 400, or, perhaps, slightly later. The author gives a wealth of information as to the origins and development of story-literature in Arabic. He describes the Persian *Hazār afsāna* with its origin; it contained 1,000 nights and less than 200 stories. It existed also in an Arabic translation, but he does not specifically call that "The Thousand and One Nights," as the earlier (Mas'ūdī) does He regarded it as a worthless and stupid book, although it is evident that he had not the learned Moslem prejudice against entertaining stories We may fairly deduce from the evidence that the first Arabic *Nights* was a straight translation of the Persian *Hazār afsāna*; that it was a comparatively small book in which each story averaged about five nights; and that it was not of much value Again, there is no evidence as to what its stories were except that they must have been of Persian origin

The next scrap of evidence is derived from an al-Qurṭī who wrote a history of Egypt under the last Fāṭimid Caliph al-'Āḍid (A.H. 555–567) In it he named specifically a book called *A Thousand and One Nights* and compared its stories to popular tales current in his time among the people We have not his history but we know this passage because it was quoted twice by al-Maqrīzī (d A H. 845) in his *Khiṭaṭ,* i, p. 485; ii, p. 181 and by al-Maqqarī (d A.H 1041) in his *Nafḥ aṭ-ṭīb, i*, p 653 This means that a *Nights,* of some form or other, was well known in Egypt in Fāṭimid times

Next comes the manuscript which Galland used It was sent to him from Syria after A D. 1700, but had evidently been written in Egypt From a note in it, it seems that it was at the Syrian Tripoli in A H. 943, A D 1536–37, and it was at Aleppo in A H 1001, A D. 1592–93. When the manuscript was written, before these dates, we do not know But we can give dates before which it could not have been written, from allusions in certain of the stories in it. In the Cycle of the Porter of Baghdad, at the beginning of the story of the second calendar, that prince tells that part of his education was in the *Shāṭibiya,* the author of which died A H 590, after al-Qurṭī's date. On the date of the story of the two Viziers, Nūr ad-Dīn 'Alī and Shams ad-Dīn Muhammad Prof. William Popper has recently gathered (*Journal of Royal Asiatic Society,* Jan. 1926) a mass of valuable material He concludes that this story cannot be earlier than the reign of Baibars, A.H. 650–76 (A D. 1260–77), and he is inclined to a date later than A.H. 706 On historical references he would also date the Hunchback Cycle after A H. 819. Further, in that Cycle, when the Barber makes his apologia in reply to the story told by the young man it is plain that he is speaking after the capture of Baghdad by Hūlāgū in A.H. 656 (A.D. 1258). But, further again, in the story told by the Christian broker, a Cairene Copt, about his dealings with the young man of Baghdad, the Khān of al-Jāwalī is mentioned. This Jāwalī died A.H. 745 (A D. 1344–45), and the date of the story can hardly be pushed back before that date and may be considerably after that date. *See* details on all these points in the present writer's article "Earlier History of the Arabian Nights" in *Journal of the Royal Asiatic Society* pp. 353–97 (July 1924).

From the above it is plain that the *Nights* to which al-Qurṭī testifies as being current in Fāṭimid times cannot have been the *Nights* of the Galland manuscript. But the Egyptian recension which Zotenberg has shown was compiled in the later 18th century and which is the present Vulgate of the *Nights,* so far as editions and translations are concerned, was based demonstrably on a sister

manuscript to that of Galland but one more complete as to the number of *Nights;* the Galland manuscript reaches only *Night 281.* On the other hand, this modern Egyptian recension has lost grievously in the course of transmission in freshness of vocabulary and wealth of details. We are left then with the apparent result that some time after A.D. 1400 an Egyptian lover of stories took the framework story of the *Nights* and built it up into a thousand and one nights, inserting the best stories current in his time that he could find An incomplete manuscript derived from his recension wandered up into Syria; others more complete remained in Egypt and formed the basis for the 18th century recension which Zotenberg identified. Still undefined is the relationship of these to certain old Syrian manuscripts which are preserved in libraries at Tübingen and Paris, and in the Rylands library at Manchester.

For the long and complicated bibliography of the *Nights* reference can be made to Victor Chauvin's *Bibliographie des Ouvrages Arabes,* pt. iv to vii (Liége, 1900–03) This is a thesaurus of the whole subject. Still worth reference is J Østrup's *Studier over Tusind og en Nat* (Copenhagen, 1891). Of this there is an abbreviated French translation by E. Galtier in *Memoires de l'Institut Français du Caire,* vol. xxvii, and a German translation by O Rescher (Stuttgart, 1925) with valuable additions bringing it to that date. English is fortunate in its direct translations from the Arabic; all, however, from the printed texts of the modern Egyptian Recension. In 1838, Henry Torrens published a very remarkable version (Calcutta and London) of the first 50 *Nights,* giving the feeling of the original in prose and verse better than almost any other Lane's incomplete version (3 vol. London, 1839–41) is from the Būlāq edition and shows his deep knowledge of Cairene Arabic; the commentary is very valuable. The version by John Payne (Villon Society, 9 vol. 1882–84) from the Calcutta edition is a faithful and complete rendering into rather sophisticated translator's English The prose part of Burton's version (*Benares,* 10 vol, 1885) is largely dependent upon Payne, but treated after Burton's fashion; the verse is his own An excellent and complete German translation by Enno Littmann is in course of publication at Leipzig; it is from the Calcutta text with additions, and five volumes out of six have appeared. The French version of J. C. Mardrus (Paris, 1899 ff.), professedly from the Būlāq edition, is unfaithful to an extensive degree and represents no known Arabic text; the same holds of the various versions derived from it in English, Spanish and Polish. (D. B. M)

THRACE, a name applied at various periods to areas of different extent. Since 1923 Thrace has been divided between Greece (Western Thrace) and Turkey (Eastern Thrace). The boundaries of the Roman province of Thrace were—north, the Haemus; east, the Euxine sea; south, the Propontis, the Hellespont and the Aegean; and west, the Nestus. The distinguishing features of the country were the chain of Rhodope (Despotodagh) and the river Hebrus (Maritza) The former separates from the Haemus at right angles, and runs southward, parallel to the Nestus, until it approaches the sea, when it takes an easterly direction. Several of the summits of this chain are over 7,000ft. in height. The Hebrus, with its tributaries, drains almost the whole of Thrace. It starts from near the point of junction of Haemus and Rhodope, and takes an easterly direction, but at Hadrianopolis it makes a sharp bend towards the south, and enters the sea nearly opposite the island of Samothrace The greater part of the country is hilly and irregular; besides Rhodope two other tolerably definite chains intersect it, one of which descends from Haemus to Adrianople, while the other follows the coast of the Euxine at no great distance inland. One district in the extreme north-west of Thrace lay beyond the watershed separating the streams that flow into the Aegean from those that reach the Danube: this was the territory of Sardica, the modern Sofia. In the later Roman period two main lines of road passed through the country. One of these skirted the southern coast, being a continuation of the Via Egnatia, from Dyrrhachium to Thessalonica, connecting the Adriatic and the Aegean; it became of the first importance after the foundation of Constantinople. The other followed a north-westerly course through the interior, from Constantinople by Hadrianopolis and Philippopolis to the Haemus, and thence through Moesia in the direction of Pannonia, taking the route by which the railway now runs from Constantinople to Belgrade.

The climate of Thrace was regarded by the Greeks as severe, and that country was spoken of as the home of the north wind, Boreas. The coast of the Euxine was feared by sailors, as the harbours were few and the sea tempestuous; but on the southern shore we find the Greek colonies of Abdera and Mesambria on the Aegean, Perinthus on the Propontis, and, the most famous of all, Byzantium (*q.v.*). Colonies were also planted in the Thracian Chersonese, between the Hellespont and the Bay of Melas; among its cities were Sestos and Callipolis (Gallipoli). In order to prevent the incursions of the Thracians, a wall was built across its isthmus, which was less than 5m. in breadth.

History.—The most striking archaeological monuments of the prehistoric period are the sepulchral mounds, which are found especially in the neighbourhood of the ancient towns. Roman implements and ornaments have been found in some of them The country was overrun several times by Darius and his generals, and the Thracian Greeks contributed 120 ships to the armament of Xerxes (Herod. vii. 185). The most powerful Thracian tribe was the Odrysae, whose king, Teres, extended his dominion so as to include the greater part of Thrace During the Peloponnesian War his son Sitalces was an ally of the Athenians against the Macedonians During the early period of the Roman empire the Thracian kings were allowed to maintain an independent sovereignty, while acknowledging the suzerainty of Rome, and it was not until the reign of Vespasian that the country was reduced to the form of a province. It was much exposed to the inroads of barbarian invaders, was overrun by the Goths on several occasions, and subsequently by the Huns; but its proximity to Constantinople caused its fortunes to be closely connected with the capital of the Eastern empire In the middle ages the northern parts of Thrace were occupied by Bulgarians; in 1361 the Turks made themselves masters of Adrianople, which became the Turkish capital. When Constantinople fell in 1453, the whole country passed into the hands of the Turks, and in their possession it remained until 1878, when the northern portion of it was placed under a separate administration, with the title of Eastern Rumelia; this province has now become a part of Bulgaria

Ancient Peoples.—The name "Thracians," from being used both ethnically and geographically, has led to confusion There were the indigenous Thracians, and also Celtic tribes, such as the Getae. These were the "red" Thracians of Greek writers, and they differed not merely in complexion, but also in their customs and religion, from the native Thracians (Herod., v. 14). The native Thracians were inferior in morals, allowing their girls complete licence until marriage. The chief native deities were Dionysus, Ares and Bendis (Artemis). The ancient Dionysiac rites, including a ritual play by "goat-men" carrying a wooden phallus, may still be seen at Bizye, the old residence of the Thracian kings (*see* R. M. Dawkins in *Hellenic Journal,* 1906, p. 191). The true Thracians were a dark-complexioned, long-skulled race, which had been in the Balkan peninsula from the stone age, closely akin to the Pelasgians (*q.v.*), to the Ligurians, and to the Iberians. In Homer, the term Thracian is applied to all the tribes dwelling from Pieria to the Euxine. There is no well-defined difference between aboriginal Thracians and Illyrians (*see* ILLYRIA). Thus there was an Illyrian tribe, Brygi; a Thracian tribe, Bryges, and, in Strabo's time, a tribe called Dardanii, then reckoned Illyrian, living next the Thracian Bessi (in whose land was the oldest oracle of Dionysus), were probably as much Thracian as Illyrian. All the Thracian and Illyrian tribes tattooed, thus being distinguished from the Celtic tribes. The Thracians differed only dialectically from the Illyrians, their tongue being closely allied to Greek. The Thracians of the region from Olympus to the Pangaean district, worked the gold and silver of that region, began to strike coins almost as early as the Greeks, and displayed on them much artistic skill. Alexander I. of Macedon, on his conquest of the Bisaltae, adopted the native coinage of their country placing on the coins his own name (*see* NUMISMATICS.) (X)

THE 20th CENTURY

Thrace was one of the three theatres of the first Balkan war of 1912, when the Bulgarians entered it and defeated the Turks in the great battle of Lule Burgas, subsequently marching up to the ramparts of Chatalja, where the armistice with the Turks was signed. With the assistance of Serbian troops the Bulgarians took Adrianople, and the Treaty of London of May 30, 1913 put back the frontier of European Turkey to a line drawn from Enos on the Aegean to Midia on the Black Sea Nearly all Thrace had thus fallen to the share of Bulgaria, but her quarrel with her allies over the spoils in Macedonia led to the second Balkan war of 1913, and the Turks took the opportunity to recapture Adrianople, to reoccupy Western Thrace and create the "independent government of Gümuljina," a mainly Moslem district.

The treaty of Constantinople of Sept 29, 1913 set back the Turco-Bulgarian frontier in Thrace to the mouth of the river Rezvaya on the Black Sea, considerably to the north of Midia, and, while making the right branch of the Maritsa the frontier on the Aegean, so drew the line between those points as to include Kirk Kilisse and Adrianople within Turkish Thrace But Gümüljina was restored to Bulgaria, with the result that 14 Moslem deputies of Western Thrace held the balance of power in Bulgaria and, under the influence of their compatriot Talaat, helped to bring Bulgaria over to the Central Empires Meanwhile the third Treaty of Bucharest fixed the Greco-Bulgarian frontier at the mouth of the Mesta; thus the Thracian coast from the Mesta to the Maritsa gave Bulgaria her coveted outlet on the Aegean. But the frontier cut the latter river and the Mustafa-Pasha (Svilen) Adrianople-Dedeagach railway so that Bulgarian trains had to traverse Turkish territory before reaching their Bulgarian port The Maritsa was consequently declared free to the transit of both states till they had made fresh lines on their own territories. The cession of this awkward bend in the railway to Bulgaria in 1915 was a further inducement to enter the War on the Turkish side. Thrace was not long left in peace, for the operations at the Dardanelles brought her again within the war zone. The Treaty of Neuilly of 1919 again changed her boundaries Bulgaria was moved back from the Thracian sea coast in favour of Greece, which by Article 27 of the Treaty of Sèvres of 1920 obtained the lion's share of Thrace as far as "a point near the mouth of the Biyuk Deré" on the Black Sea, and "a point on the sea of Marmora about one kilometre southwest of Kalikratia"—in other words, up to the Chatalja lines.

But the Allies undertook to make the Maritsa an international river and "to ensure the economic outlet of Bulgaria to the Aegean" by Article 48 of the Treaty of Neuilly This they effected —in theory—by "the Thracian Treaty," signed on the same day as that of Sèvres, which decreed, as a condition of the recognition of Greek sovereignty over the former Bulgarian territories in Thrace, that Bulgaria should have "freedom of transit over the territories and in the ports assigned to Greece in the present Treaty," that "in the port of Dedeagach Bulgaria will be accorded a lease in perpetuity, subject to determination by the League of Nations, of a zone," and that Dedeagach be "declared a port of international concern," free to all members of the League. In practice, Bulgaria did not avail herself of this provision, rejecting Venizelos' offer in 1922 of a lease of the port and preferring a corridor and actual possession. The Greek tenure of Eastern Thrace was brief After the disaster in Asia Minor, Article 2 of the second Treaty of Lausanne of July 24, 1923 restored Eastern Thrace up to the Maritsa to Turkey, leaving Western Thrace, *minus* the enclave of Karagach, to Greece. By conventions 3 and 6, on either side of these Greco-Turkish and Bulgaro-Turkish frontiers in Thrace demilitarized zones of about 30 km. were established and existing fortifications ordered to be dismantled, and the Moslem inhabitants of Western Thrace were exempted from the obligatory exchange of populations. Thus Thrace became divided between Turkey, Greece and Bulgaria.

Economic Conditions.—Heavy damage was inflicted on south-western Thrace, the most fertile portion of the country, during the Balkan wars of 1912–13. Railway communications are complicated by the unscientific frontier near Adrianople, whereby the line from Western Europe to Constantinople traverses a tiny strip of Turkish territory, re-enters Greece and then recrosses into Turkey The Turks have in hand (1928) a scheme to build a line farther to the north, which will obviate the necessity of passing through Greek territory Thrace is in a primitive condition, but amongst the steps taken by the Turkish Government to improve the position is the establishment of a modern sugar factory and the encouragement of modern methods in the cheese manufacture of the Adrianople area. Turkish Thrace is now ethnologically overwhelmingly Turkish, while the Greeks find the remaining Muslims of the western half useful for the tobacco culture. The demilitarization of the Gallipoli peninsula by the Lausanne Treaty should spare Thrace the spectacle of hostile armies. But the situation created by the treaties following the World War must be regarded as provisional and artificial

THRASEA PAETUS, PUBLIUS CLODIUS, Roman senator and Stoic philosopher. lived during the reign of Nero He was the husband of Arria the daughter of Arria (*q.v.*), father-in-law of Helvidius Priscus, and a friend and kinsman of the poet Persius At first he was treated with great consideration by Nero, probably owing to the influence of Seneca, and became consul in A D. 56 and one of the keepers of the Sibylline books. In 59 Thrasea retired from the senate without voting after the emperor's letter justifying the murder of Agrippina had been read. In 62 he prevented the execution of the praetor Antistius, who had written a libel upon the emperor, and persuaded the senate to pass a milder sentence. From this time (63) till his death in 66 Thrasea retired into private life and did not enter the senate-house again Various charges were brought against him, and the senate, awed by the presence of large bodies of troops, condemned him to death When the news was brought to Thrasea at his house, where he was entertaining a number of friends, he retired to his room and had the veins of his arms opened He wrote a panegyric on Cato of Utica, largely used by Plutarch

See Tacitus, *Annals* (ed Furneaux), xiii 49, xiv 12, 48, xv. 20–22, xvi. 21–35, containing a full account of his trial and condemnation.

THRASHER, a group of birds belonging to the same American family *Mimidae* as the mocking-bird (*q v.*). Perhaps the best of these accomplished songsters is Sennett's thrasher (*Toxostoma longirostre*) of south-east Texas and north-east Mexico, but the brown thrasher (*T. rufum*) of eastern North America also has a fine song A third species is the sage thrasher (*Oroscoptes montanus*) of the South-western States of the United States

THRASHING or **THRESHING,** the process by which the grain or seed of cultivated plants is separated from the husk or pod which contains it. The flail was the chief means of threshing grain until about 1860

The flail consisted of two pieces of wood, the handstaff or helve and the beater, fastened together loosely at one end by a thong of rawhide or eelskin, which made a very durable joint. The handstaff is a light rod of ash about 5 ft. long, slightly increasing in girth at the farther end to allow for the hole for the thong to bind it to the beater; its length enabled the operator to stand upright while working The beater is a wooden rod about 30 in. long, made of ash, though a more compact wood such as thorn is less likely to split. This also has a hole at one end for the thong to bind it to the handstaff. The shape of the beater was cylindrical, of about 1¼ in. diam. and constructed so that the edge of the grain of the wood received the force of the blow; 30 to 40 strokes per min. was the average speed.

After the grain had been beaten out by the flail or ground out by other means the straw was carefully raked away and the corn and chaff collected to be separated by winnowing when there was

a wind blowing. This process consisted in tossing the mixture of corn and chaff into the air so that the wind carried away the chaff while the grain fell back on the thrashing floor. The best grain fell nearest while the lightest was carried some distance before falling, thus a rough-and-ready grading of the grain was obtained. It was also performed when there was no wind by fanning while pouring the mixture from a vessel. Later on a fanning or winnowing mill was invented.

The flail is still in use for special purposes such as flower seeds and also where the quantity grown is so small as to render it not worth while to use a thrashing mill For a day's work with it a fair average quantity was 8 bushels of wheat, 30 bushels of oats, 16 bushels of barley, 20 bushels of beans, 8 bushels of rye or 20 bushels of buckwheat.

Meikle's Machine.—The first really successful thrashing machine—the type which is embodied in modern thrashers—was invented by a Scotsman named Andrew Meikle in 1786 In this the loosened sheaves were fed, ears first, from a feeding board between two fluted revolving rollers to the beating cylinder This cylinder or "drum" was armed with four iron-shod beaters or spars of wood parallel to its axle, and these striking the ears of corn as they protruded from the rollers knocked out the grain The drum revolved at 200 to 250 revs. per min. and carried the loose grain and straw on to a concave sieve beneath another revolving drum or rake with pegs which rubbed the straw on to the concave and caused the grain and chaff to fall through Another revolving rake tossed the straw out of the machine The straw thus passing under one peg drum and over the next was subjected to a thorough rubbing and tossing which separated the grain and chaff from it These fell on to the floor beneath, ready for winnowing

The present-day thrashing machine embodies the main features of Meikle's and will thrash up to 16 qrs. of oats per hr, according to its size For further details *see* HARVESTING MACHINERY

Thrashing Work.—The minimum number of hands required in Great Britain are: An engine-driver, a feeder, a sackman and ten other men to handle the sheaves, straw, chaff, grain, etc., while half as many more may be needed where the sheaves or grain have to be carted, as when the thrashing is done in the field in harvest time An 8-h p steam engine is the usual motive power, but the development of the oil engine has provided a very satisfactory substitute. The engine is usually of the "traction" type, so that it can move the thrashing machine or "barn work" (as it is sometimes called) and elevator from place to place, but a further advance has been to combine oil engine and thrasher in one so that the combination is self-moving. The usual quantities thrashed with a "double blast finishing machine," as described, in the United Kingdom are, with a 5 ft. wide drum, from 60 to 80 bushels per hour of wheat and one-third to one-half more of oats and barley.

Sometimes the straw is stacked loose, while sometimes it is tied up with twine by a tier exactly like that on a "string binder" and then stacked up. Where all the straw is used at the farm for fodder, etc., the fixed thrashing machine set up in the barn is the most convenient The sheafed corn has to be carried to it, but, on the other hand, everything is under cover, the work can be done on a wet day, and all the products of thrashing in the shape of grain, straw, cavings, chaff, etc, are kept dry. In the great corn districts, however, the portable thrasher is most convenient; it is set alongside the stack and only the grain and chaff are carried under cover, while the thrashed straw, etc., is restacked up on the spot as the work goes on. (P. McC.)

THRASYBULUS, an Athenian general, whose public career began in 411 B.C., when he frustrated the oligarchic rising in Samos (*see* PELOPONNESIAN WAR). Elected general by the troops, he effected the recall of Alcibiades and assisted him in the ensuing naval campaigns, contributing to the victories of Cynossema (411) and Cyzicus (410). He commanded a ship at Arginusae and after the engagement was commissioned with Theramenes (*q.v.*) to rescue the men on the wrecks.

In 404, when exiled by the Thirty Tyrants he retired to Thebes. Late that year, with seventy men, he seized Phyle, a hill fort on Mt. Parnes. A force sent by the Thirty was routed by a surprise attack Thrasybulus then gained the Peiraeus, 1,000 strong, and held Munychia against the oligarchs. Eventually a Spartan expedition under king Pausanias arrived and effected a settlement by which the democracy was restored. Thrasybulus was now the hero of the people; but a decree by which he secured the franchise for all his followers, including many slaves, was rescinded as illegal

In 395 Thrasybulus induced Athens to join the Theban league against Sparta, and in 389 he led a new fleet of 40 ships against the Spartans at Rhodes. Sailing first to the Bosporus he effected a democratic revolution at Byzantium and renewed the corn-toll After a successful descent on Lesbos and the renewal of the 5% import tax at Thasos and Clazomenae he sailed south in quest of further contributions, and was killed in a skirmish at Aspendus

See Thucydides, viii 75–105; Xenophon, *Hellenica;* Lysias, *c. Eratosth* 55–61 and *c Ergocl* 5, 8; and *Const ath.* xl Diodorus xiii., xiv, Justin v. 9, 10, and Nepos depend almost wholly on Xenophon.

THREAT, a statement made for the purpose of overcoming the will of the person to whom it is addressed. The employment of threats or other forms of intimidation to induce a person to enter into a contract will give the right to sue for its rescission or avoidance, or to sue for damages occasioned by entering into the contract. (*See* COERCION; CONTRACT.)

In criminal law the sending of threatening letters (or causing them to be received), demanding with menaces and without reasonable cause money or other valuable thing, is a felony It is also a felony to threaten to accuse a person of a crime for the purpose of extorting money, or merely to demand money or other property, without having any claim to it, by means of a threat. (*See* BLACKMAIL, LARCENY)

In the United States, threat very largely is covered by statutes in the several States, with variations, but following in the main the English law.

THREE BODIES, PROBLEM OF, the problem of determining the motion of three bodies moving under no influence but that of their mutual gravitation. No general solution of this problem is possible. As practically attacked it consists in the problem of determining the perturbations or disturbances in the motion of one of the bodies around the principal or central body, produced by the attraction of the third Examples are the motion of the moon around the earth as disturbed by the action of the sun, and of one planet around the sun as disturbed by the action of another planet.

THREE-COLOUR PROCESS: *see* COLOUR PRINTING.

THREE RIVERS or TROIS RIVIÈRES, a city and port of entry of Quebec, Canada, and capital of St. Maurice county, situated at the confluence of the rivers St Maurice and St Lawrence The St Maurice flows in from the north, and, being divided at its mouth by two islands, the channels give the town its name. It is on the line of the Canadian Pacific and Canadian National railways, 78 m S.W. of Quebec and 92 m. N E. of Montreal. Founded in 1634 by Champlain, Three Rivers is one of the oldest towns in Quebec. It is the centre of a large lumber trade, which is carried on along the St. Maurice and its tributaries. Some miles from the city are the St. Maurice forges, where iron wares were manufactured as early as the 17th century. The city is the seat of a Roman Catholic bishopric. A large trade is carried on in lumber, grain, cattle, etc., which are shipped to South America, the West Indies, Great Britain and the United States, and a great development has been caused by the utilization of the water-power of the St Maurice at Shawinigan, Grand'Mère and other falls, for the manufacture of wood pulp. As a result, the population, long stationary or slightly declining, increased from 8,334 (1891) to 9,981 (1901) and 22,367 (1921).

THRING, EDWARD (1821–1887), English schoolmaster, was born at Alford, Somerset, on Nov. 19, 1821. He was educated at Eton and at King's college, Cambridge. On leaving the university in 1846 he was ordained, and served for a short time in two curacies. In 1853 he became headmaster of Uppingham school, a post which he retained until his death in 1887 Thring found only 25 boys in the school, but he raised it, both in numbers and repute, to the rank of the best English public schools

Among the distinctive features of his plans and achievements were: (1) his strong sense of the need for a closer study of the characteristics of individual boys than is generally found possible in large public schools; (2) his resolute adherence to the discipline of the ancient languages, in connection with English, as the staple of a liberal education; (3) his provision of additional employments and interests, in studies and in games, to suit the aptitudes of different pupils; (4) the value he attached to the aesthetic side of school training, to music and to drawing and to the artistic decoration of the schoolrooms; and above all (5) his rebellion against mere routine, and his constant insistence on the moral purpose of a school as a training-ground for character

See J. H. Skrine, *Uppingham by the Sea* (1878) and *A Memory of Edward Thring* (1889); J. G. Fitch, *Educational Aims and Methods* (1889); G R Parkin, *Life of Edward Thring* (1898), H. D Rawnsley, *Edward Thring, Teacher and Poet* (1900), W F. Rawnsley, *Edward Thring, Maker of Uppingham School* (1926).

THROAT, the term applied to the front external part of the neck from below the chin to the collar-bone in human and animal anatomy, and to the internal parts, which include the gullet, viz. the fauces, pharynx and oesophagus and the windpipe, viz, the larynx and trachea (*see* PHARYNX, ALIMENTARY CANAL and RESPIRATORY SYSTEM. *Anatomy;* and for diseases *see* PHARYNGITIS, LARYNGITIS, DIPHTHERIA, TONSILLITIS and OESOPHAGUS)

THROAT, DISEASES OF: *see* EAR, NOSE AND THROAT, DISEASES OF

THROCKMORTON (or THROGMORTON), **FRANCIS** (1554–1584), English conspirator, was the son of Sir John Throckmorton of Feckenham in Warwickshire, and his wife Margery Puttenham. Sir John had been concerned in Wyat's rebellion against Queen Mary Tudor, but was afterwards known as a sympathizer with the Roman Catholic party in the reign of Queen Elizabeth, and in 1580 was removed from his office of chief justice of Chester for irregularities in his office, but probably because he was suspected of disloyalty by the government Francis entered Hart Hall, Oxford in 1572, and in 1576 he was enrolled in the Inner Temple. At Oxford he came under the influence of the Roman Catholics, and when Campion (*q v*) and Parsons came to England in 1580 to conduct the Jesuit propaganda against Queen Elizabeth, Francis Throckmorton was one of a society of members of the Inner Temple who united to hide and help them. In that year he went abroad where he consorted with exiled papists, and engaged in treasonable intrigues In 1583 he returned to act as the confidential agent of a conspiracy which had for its object the invasion of England by a French force for the purpose of releasing Mary Queen of Scots and restoring the papal authority.

Throckmorton occupied a house on Paul's wharf, London, which served as a meeting-place for the conspirators The suspicions of the government being aroused, Throckmorton was arrested in October 1583. He was ciphering a letter to Queen Mary when the constables came upon him, but he found time to send a casket of compromising papers to Mendoza, and a card in cipher in which he promised to reveal nothing On being threatened with a second application of the torture, however, his strength and courage failed and he made a full confession His trial, took place on May 21, 1584, and he was executed at Tyburn on the 10th of July The arrest and confession of Throckmorton eventually led to the expulsion of the Spanish ambassador and so to war with Spain

THROCKMORTON (or THROGMORTON), **SIR NICHOLAS** (1515–1571), English diplomatist and politician, was the son of Sir George Throckmorton of Congleton in Warwickshire, and uncle of the conspirator Francis Throckmorton (*See* above.) Brought up in the household of Catherine Parr, the last wife of Henry VIII., he was favourable to the reformers in religion. He sat in parliament from 1545 to 1567. During the reign of Edward VI. he was in high favour with the regents. In 1547 he was present at the battle of Pinkie during the invasion of Scotland. When on the death of Edward VI. an attempt was made to place Lady Jane Grey on the throne, he contrived to appear as the friend of both parties, and secured the favour of Queen Mary Tudor. He was, however, suspected of complicity in Wyat's rebellion in 1554, was brought to trial but was acquitted.

Throckmorton was, however, detained in the Tower till the following year. But he made his peace with Queen Mary. After the accession of Elizabeth he rose rapidly into favour. He became chamberlain of the exchequer, and from May 1559 to April 1564 he was ambassador in France. During this period, in which he was associated with Sir Thomas Smith, Throckmorton became acquainted with Mary Queen of Scots. He conducted the negotiations which accompanied her return to Scotland, and though he supported the reformers on political grounds, he became her personal friend. On returning to England he was sent as ambassador to Scotland in May 1565, to prevent Queen Mary's marriage with Darnley, which however he was unable to do After the murder of Darnley he was again sent to Scotland in June 1567 with the still more hopeless task of persuading the Scottish barons who had just imprisoned the queen to restore her to her authority.

Throckmorton's known friendship for Queen Mary and his constant support of her claim to be recognized as Elizabeth's successor, made him an unwelcome representative of England in that crisis In Edinburgh Throckmorton could effect little, but he exerted himself to secure the personal safety of the queen He offended his mistress by showing his instructions to the Scottish barons, and was recalled in August. In 1569 he fell under suspicion during the duke of Norfolk's conspiracy in favour of Mary, and was imprisoned for a time at Windsor, but was not further proceeded against He died on Feb. 12, 1571. Sir Nicholas married Anne Carew, and his daughter Elizabeth became the wife of Sir Walter Raleigh.

THROMBOSIS AND EMBOLISM. Under normal circumstances the blood within a blood-vessel remains fluid so long as the lining endothelium is living, but if from injury, or extension of inflammation from outside or circulatory failure from weakness of heart action the nutrition of the endothelium in any vessel is impaired, coagulation of blood or thrombosis occurs. Since the veins have thinner walls than arteries and the blood flow is slow in them owing to their relative greater diameter spontaneous thrombosis is far commoner in veins than in arteries

A thrombus is always most extensive in that direction in which the blood pressure is least; hence with reference to the heart, the greater part of an arterial thrombus is distal, a venous thrombus is proximal. On the proximal and distal sides respectively thrombosis extends at least as far as the nearest lateral branch The effect of thrombosis depends upon the seat of blockage and its extent as well as on the character of the vessels affected and on the question whether the clot is aseptic or septic. In advanced old age when heart action is feeble thrombosis is apt to occur in the cerebral and meningeal veins leading to local death of brain matter (cerebral softening). When the formation of clot once begins the process is liable to extension partly because the primary cause is central, partly because every portion of clot is foreign material upon which more clot will be deposited. Hence in old age cerebral thrombosis in time—it may be a week or more—ends fatally.

In another condition in which the wall of arteries is the seat of advanced calcareous degeneration (atheroma) even a fairly normal degree of heart action is unable to prevent extensive clotting in arteries of distal parts (*e g.*, leg) and collateral circulation being unattainable gangrene on the part occurs. Where the vessel is larger and particularly where it is the seat of aneurism (*q.v*) this same process of thrombus-formation is conservative, for the deposited blood clot strengthens the weakened vessel wall and sometimes even brings about complete filling up of a saccular aneurism.

Where the thrombus is septic the whole series of changes is dominated by the local presence of bacteria; in most cases a local abscess forms and the character of the morbid condition is determined by that fact (*see* ABSCESS; INFLAMMATION; PATHOLOGY). In "white leg," a condition usually met with in women after childbirth, in which thrombosis extends from the uterine sinuses into the iliac veins and thence into the femoral vein the seriousness of the condition is infinitely greater if the clot be septic.

The cohesion of a thrombus varies widely and is much reduced where suppurative changes are involved. Moreover the thrombus is rarely attached to the vessel wall over its whole extent; usually

the greater portion is non-adherent and simply occupies the lumen of the vessel Hence variations in posture, sudden movement, even such variations as are occasioned by cardiac action are apt to detach portions of thrombus. Such detached portions are then carried in the blood stream (embolism) to distant parts. Where they will become lodged and what will happen at the seat of their lodgement depends upon their size, the site of their parent thrombus and above all on their aseptic or septic character

If the parent thrombus be formed in the systemic veins or the right side of the heart (particularly the auricular appendix) the embolus will be carried to the lungs and may be large enough to block a main pulmonary artery and cause sudden death Many cases of sudden death after childbirth or surgical operation are due to such "pulmonary embolism." If smaller the clot may be arrested in the substance of the lung itself leading to localized obliteration of the corresponding amount of pulmonary tissue This will give rise to a variable degree of distress, but recovery is not impossible particularly if the clot be aseptic If septic it occasions local abscess or gangrene and empyema (*q v*) If the parent thrombus be in the left side of the heart (*q.v*), left auricular appendix or on a diseased mitral or aortic valve (*see* HEART, DISEASES OF) the embolus is carried into one of the systemic arteries and the effect depends upon whether the blocked vessel is an "end artery" or has anastomotic branches (*see* ARTERIES) If an end artery, *e g*, the middle cerebral or the arteries of kidney or spleen, local death of the part normally supplied by the blocked artery occurs and an "infarct" results; if the blocked artery has free anastomoses, *e g*, superior mesenteric artery, practically no ill effects follow unless the embolus be septic

When septic emboli are carried from the left ventricle, whether locally formed or carried thither from a focus in the lung, they cause abscesses wherever lodged and produce the form of blood poisoning known as pyaemia (*see* SEPSIS). Since venous blood from the greater part of the alimentary tract is carried to the liver by the portal system, thrombosis in the alimentary tract is liable to be followed by hepatic embolism; hepatic abscess in association with amoebic dysentery (*q v*) and pylephlebitis following appendicitis (*see* LIVER, DISEASES OF, APPENDICITIS) essentially depend upon lodgement in the liver of an infected embolus carried in the portal stream from the intestine

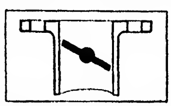
Though blood clot is the commonest material of which an embolus is composed, fat emboli and air emboli are known, the former occurring when severe fracture of bone has liberated fat from the bone marrow, the latter when air has gained entrance to a vein. (W. S. L-B)

THRONE. The throne is the ancestor of all chairs, which were originally symbols of authority and rule. In early days and in Oriental countries thrones were of barbaric magnificence. Solomon's was of ivory "overlaid with the best gold" There were two figures of lions at the sides, with two other lions on each of the six steps The remains of a throne in rock-crystal were found in the ruins of Sennacherib's palace The Persian throne made for Abbas the Great was of white marble This monarch in 1605 presented a throne to the Russian Tsar Boris, covered with sheets of gold and decorated with precious stones and pearls. Michael Feodorovitch, grandfather of Peter the Great, had a "golden throne" set with 8,000 turquoises, 1,500 rubies, 4 great amethysts and 2 large topazes. One of the glories of Delhi, until it was sacked by Nadir Shah, was the "peacock throne," which was ascended by silver steps and stood on golden feet set with jewels. It was adorned with two open peacocks' tails composed of magnificent diamonds, rubies and other stones.

The mediaeval emperors of Byzantium had a throne, which is supposed to have been imitated from, as well as named after, that of Solomon, was guarded by golden lions, which rose to their feet and roared when some artful mechanism was set in motion An exceedingly ancient chair of State is the so-called throne of Dagobert. The most recent writers on this remarkable relic suggest that it is a bronze copy of Dagobert's golden throne. However that may be, there can be no doubt that it possesses at least one illustrious modern association, for Napoleon sat in it when he distributed the first decorations of the Legion of Honour in his camp at Boulogne in 1804. The throne which Napoleon had made for himself was a heavy gilded chair with an abundance of Egyptian ornament, lions' heads and imperial eagles. One of the many curiosities of a conclave for the electing of a pope is that every cardinal present occupies a throne, since, during the vacancy of the Holy See, each member of the Sacred college is a potential sovereign. When the election has taken place the canopy of every throne is lowered, with the exception of that occupied by the new pontiff The palaces of the great Roman nobles contained—and still in some cases contain—a throne for use in the event of a visit from the pope. The papal throne itself is an antique bronze chair which stands in St Peter's. The British coronation chair is not, properly speaking, a throne, since it is used only during a portion of the coronation ceremonies The actual throne of Great Britain is the oaken Gothic chair in the House of Lords occupied by the sovereign at the opening and prorogation of parliament.

THROOP, an anthracite-mining borough of Lackawanna county, Pennsylvania, U S A., on the Lackawanna river, 3 m N E. of Scranton; served by the Lackawanna and the New York, Ontario and Western railways Pop. (1920) 6,672 (35% foreign-born white); 1928 local estimate 9,500 The borough was incorporated in 1894

THROTTLE is a valve which controls admission of steam to an engine or turbine or of an explosive mixture to an internal-combustion engine or of draught to a boiler furnace The amount of opening can be variously regulated by hand, by foot or by a governor in different cases The butterfly throttle is an established type for large valves, and is a favoured type in the small passages which lead from carburettors in automobile and aero-engines (*see* fig) The turning of the spindle causes the valve gradually to close the passage An altitude cock is employed in conjunction with the throttle for aero-engines to provide compensation for the different conditions at various heights Large throttle-valves for steam engines have a piston-valve construction with packing rings, and the action is such that opening and closing can be performed with great ease Governor control acts on a throttle to regulate the engine speed, in winding engines the safety overwinding apparatus closes the throttle and applies the brakes in case of neglect on the part of the driver to reduce speed or stop at the correct times. Big rolling-mill engines are throttled and reversed with great precision by a steam servo-motor mechanism set in motion by the driver's control lever



THE BUTTERFLY THROTTLE PIVOTED IN THE OUTLET TUBE OF A CARBURETTOR

THROWING THE DISCUS: *see* DISCUS THROWING

THRUSH, the name of two English species of the genus *Turdus,* the type of the family *Turdidae;* and of six American species of the family The first of these is the song thrush or mavis (*T. philomelus*), one of the finest songsters in Europe Common throughout Europe, this bird has a brown back and a speckled breast in both sexes

It feeds very largely on worms and snails, which latter it "shells" by beating on a stone and then rubbing off the fragments of the mollusc's "house" It is an early breeder, rearing two broods a year; the nest, a deep cup, is lined with mud, cow-dung and rotten wood, formed into a smooth layer by the pressure of the bird's breast The eggs, four or five in number, are a bluish green, spotted with black

The second species is the missel thrush (*T viscivorus*) also called mistletoe thrush, from its fondness for the berries of that plant, and storm-cock, from its habit of singing in squally weather. It is larger than the last species, reaching a length of 11 in. Otherwise it resembles its relative in appearance, but is greyer and has a white edge to the tail Its song is loud and wild, but less sweet than that of the mavis. The bird boldly attacks marauding crows, jays and even cats, driving them away from its nest. The hermit thrush (*Hylocichla guttata*) of North America is the finest songster of the continent. The rufous tail and whitish eye ring are distinctive features. The wood-thrush (*H. mustelina*), is little inferior to the last as a singer and has spotted sides as well as breast. The olive-backed thrush (*H. ustu-*

lata) has a similar lovely song.

The genus *Turdus* includes also the blackbird (*q.v.*), ring-ousel (*see* OUSEL), fieldfare (*q.v.*), redwing (*q.v.*), and others. Included in the *Turdidae* are the wheatears, stonechats and whinchats (*see* WHEATEAR), redstarts (*q.v.*), robins (*see* REDBREAST), and hedge sparrows (*see* SPARROW). The "ant-thrushes" belong to a different family (*see* PITTA).

THRUSH, a contagious disease of nursing infants, known also as sprue or infantile sore mouth It is caused by a fungus (*Oidium albicans* or *Saccharomyces albicans*) which produces small, roundish, white patches on the lining membrane of the mouth and throat and also on the surface of the tongue. These patches, called *aphthae*, consist of slight elevations of the outer (epithelial) layer of the mucous membrane, covering a small quantity of watery (serous) fluid. When this outer layer, which contains the fungoid growth, peels off, a raw surface is exposed. During an attack, which is of about 10 days' duration, crops of *aphthae* usually succeed each other at brief intervals, rendering the mouth very sore, so that sucking becomes extremely painful The onset of the disease is accompanied by fever, colic and diarrhoea. Thrush rarely occurs in infants of normal health, and is dangerous only when the *aphthae* develop a gangrenous condition. However, nursing infants whose normal vigor has been depressed by eruptive diseases, pneumonia or intestinal disorders, are liable to attack. Effective preventive measures require not only absolute cleanliness of nipples and nursing bottles but also sterilization of milk and other food. When the characteristic *aphthae* have appeared a thorough but gently managed washing of the mouth with a solution of boracic acid, potassium permanganate or other mild antiseptic is recommended.

THRUST BLOCK: *see* BEARINGS, SHIPBUILDING.

THUBURBO MAIUS (mod HENCHIR-KASBAT), an ancient city of Roman North Africa, in the province of Africa proper; 2 m. N. of the station of Pont-du-Fahs on the railway from Tunis to Kef. Octavian founded it near a native town, which was fused with it under Commodus The forum and its surroundings have been completely excavated The Capitolium is well preserved

See A. Merlin, *Le Forum de Thuburbo Maius* (1922).

THUBURSICU NUMIDORUM (mod. KHAMISSA), some 20 m. by road S W. of South Ahras, the junction of the railway to Tebessa from the main line from Algiers to Tunis It was originally a native town, and became a Roman municipality under Trajan There are extensive Roman remains, including two temples, a large civil basilica, and a well preserved theatre

THUCYDIDES (Θουκυδίδης), Athenian historian. Materials for his biography are scanty, and the facts are of interest chiefly as aids to the appreciation of his life's labour, the *History of the Peloponnesian War.* He was anciently believed to have been born in or about 471 B C, but modern criticism inclines to a later date, about 460 (*see* Busolt, *Gr Gesch* iii, pt 2, p. 621) Thucydides' father Olorus, a citizen of Athens, belonged to a family which derived wealth from the possession of gold-mines at Scaptē Hylē, on the Thracian coast opposite Thasos His supposed connection with Miltiades's family was presumed from a similarity of names (Olorus was the name of Miltiades's father-in-law), and rests on no surer evidence It is plain, too, that the statement that his tomb was at Athens, a statement containing one manifestly anachronistic detail, is not to be trusted No one knew where or how he died. Even in antiquity there were three or four legends on the question, all of them obvious guesses As to the date of his death, it cannot have been very long after his return to Athens either at, or shortly after the time of the Tyranny of the 30.

The development of Athens during the middle of the 5th century was, in itself, the best education which such a mind as that of Thucydides could have received The expansion and consolidation of Athenian power was completed, and the inner resources of the city were being applied to the embellishment and ennoblement of Athenian life (*see* CIMON; PERICLES). Yet the *History* tells us nothing of the literature, the art or the social life under whose influences its author had grown up. The "Funeral Oration" contains, indeed, his general testimony to the value and the charm of those influences But he leaves us to supply all examples and details for ourselves. Beyond a passing reference to public "festivals," and to "beautiful surroundings in private life," he makes no attempt to define those "recreations for the spirit" which the Athenian genius had provided in such abundance. He alludes to the newly-built Parthenon only as containing the treasury; to the statue of Athena Parthenos which it enshrined, only on account of the gold which, at extreme need, could be detached from the image; to the Propylaea and other buildings with which Athens had been adorned under Pericles, only as works which had reduced the surplus of funds available for the war He makes no reference to Aeschylus, Sophocles, Euripides, Aristophanes; the architect Ictinus, the sculptor Pheidias; the physician Hippocrates, the philosophers Anaxagoras and Socrates Herodotus, if he had dealt with this period, would have found countless occasions for invaluable digressions on men and manners, on letters and art The difference between the methods of the two historians arises from the fact that Thucydides was writing of events which were contemporary with the audience for which he wrote, whereas Herodotus dealt with the story of a war which had taken place 30 years before the time of his writing, and of preliminaries of that war which extended into an unstoried past.

The biography which bears the name of Marcellinus states that Thucydides was the disciple of Anaxagoras in philosophy and of Antiphon in rhetoric. There is no evidence to confirm this tradition But Thucydides and Antiphon at least belong to the same rhetorical school and represent the same early stage of Attic prose It is probable that both of them were fired with enthusiasm for that Sicilian Greek rhetoric with which Gorgias amazed the Athens of 427. Both writers used words of an antique or decidedly poetical cast; both point verbal contrasts by insisting on the precise difference between terms of similar import, and both use metaphors somewhat bolder than were congenial to Greek prose in its riper age The differences, on the other hand, between the style of Thucydides and that of Antiphon arise chiefly from two general causes. First, Antiphon wrote for hearers, Thucydides for readers; the latter, consequently, can use a degree of condensation and a freedom in the arrangement of words which would have been hardly possible for the former Again, the thought of Thucydides is often more complex than any which Antiphon undertook to interpret, and the greater intricacy of the historian's style exhibits the endeavor to express each thought[1]. Few things in the history of literary prose are more interesting than to watch that vigorous mind in its struggle to mould a language of magnificent but immature capabilities The obscurity with which Thucydides has sometimes been reproached often arises from the very clearness with which a complex idea is present to his mind, and his strenuous effort to present it in its entirety. He never sacrifices thought to language, but he will sometimes sacrifice language to thought. A student may always be consoled by the reflection that he is not engaged in unravelling a mere rhetorical tangle Every light on the sense will be a light on the words; and when, as is not seldom the case, Thucydides comes victoriously out of this struggle of thought and language, having achieved perfect expression of his meaning in a sufficiently lucid form, then his style rises into an intellectual brilliancy (thoroughly manly, and also penetrated with intense feeling) which nothing in Greek prose literature surpasses In one sense, a moral sense, Thucydides is unique among Greek authors. To him the "good" is not a term with the peculiar Greek connotation of it, but one which he uses with the same meaning which it possesses to-day.

The uncertainty as to the date of Thucydides' birth renders futile any discussion of the fact that before 431 he took no prominent part in Athenian politics. If he was born in 455, the fact needs no explanation; if in 471, it is possible that his opportunities were modified by the necessity of frequent visits to Thrace, where the management of such an important property as the gold-mines must have claimed his presence. The manner in which he refers to his personal influence in that region is such as to suggest that he had sometimes resided there (iv. 105, 1). He was at Athens in the spring of 430, when the plague broke out. If his account of the symptoms has not enabled physicians to

[1]*See* Jebb's *Attic Orators*, i. 35.

agree on a diagnosis of the malady, it is at least singularly full and vivid. He had himself been attacked by the plague; and, as he briefly adds, "he had seen others suffer."

The turning point in the life of Thucydides came in the winter of 424. He was then 47 (or, according to Busolt, about 36), and for the first time he is found holding an official position. He was one of two generals entrusted with the command of the regions towards Thrace (τὰ ἐπὶ Θρᾴκης), a phrase which denotes the whole Thracian seaboard from Macedonia eastward to the vicinity of the Thracian Chersonese, though often used with more special reference to the Chalcidic peninsula His colleague in the command was Eucles. About the end of Nov 424 Eucles was in Amphipolis, the stronghold of Athenian power in the north-west To guard it with all possible vigilance was a matter of peculiar urgency at that moment. The ablest of Spartan leaders, Brasidas (*q v*), was in the Chalcidic peninsula, where he had already gained rapid success; and part of the population between that peninsula and Amphipolis was known to be disaffected to Athens Under such circumstances we might have expected that Thucydides who had seven ships of war with him, would have been ready to cooperate with Eucles It appears, however, that, with his ships, he was at the island of Thasos when Brasidas suddenly appeared before Amphipolis Eucles sent in all haste for Thucydides, who arrived with his ships from Thasos just in time to beat off the enemy from Eion at the mouth of the Strymon, but not in time to save Amphipolis The profound vexation and dismay felt at Athens found expression in the punishment of Thucydides, who was exiled.

From 423 to 404 Thucydides lived on his property in Thrace, but much of his time appears to have been spent in travel He visited the countries of the Peloponnesian allies (*cf.* his account of the battle of Mantinea in 418, the Spartan version of the story), recommended to them by his quality as an exile from Athens; and he thus enjoyed the rare advantage of contemplating the war from various points of view He speaks of the increased leisure which his banishment secured to his study of events He refers partly, doubtless, to detachment from Athenian politics, partly also, we may suppose, to the opportunity of visiting places signalized by recent events and of examining their topography The local knowledge which is often apparent in his Sicilian books was acquired at this period He visited Syracuse after the siege was over This is shown by the accuracy of his topography, and by the fact that his knowledge of affairs at Athens contemporary with the siege came to an end at the time of the departure from Athens of the last reinforcements sent to Syracuse, showing that he drew information from the Athenian prisoners The mind of Thucydides was naturally judicial, and his impartiality (which seems almost superhuman by contrast with Xenophon's *Hellenica*) was in some degree a result of temperament. But it cannot be doubted that the evenness with which he holds the scales was greatly assisted by his experience during these years of exile

His own words make it clear that he returned to Athens, at least for a time, in 404, though the precise date is uncertain. The older view was that he returned some six months after Athens surrendered to Lysander More probably he was recalled by the special resolution carried by Oenobius prior to the acceptance of Lysander's terms (Busolt, *ibid*, p. 628). The preponderance of testimony certainly goes to show that he died in Thrace, and by violence It would seem that, when he wrote chapter 116 of his third book, he was ignorant of an eruption of Etna which took place in 396 There is indeed, strong reason for thinking that he did not live later than 399 The abruptness with which the *History* breaks off agrees with the story of a sudden death. The historian's daughter is said to have saved the unfinished work and to have placed it in the hands of an editor This editor, according to one account, was Xenophon, to whom Diogenes Laërtius (ii 6, 13) assigns the credit of having "brought the work into reputation, when he might have suppressed it." The tradition is, however, very doubtful; it may have been suggested by a feeling that no one then living could more appropriately have discharged the office of literary executor than the writer who, in his *Hellenica*, continued the narrative

The History.—At the outset of the *History* Thucydides indicates his general conception of his work, and states the principles which governed its composition His purpose had been formed at the very beginning of the war, in the conviction that it would prove more important than any event of which Greeks had record. The leading belligerents, Athens and Sparta, were both in the highest condition of effective equipment. The whole Hellenic world (including Greek settlements outside of Greece proper) was divided into two parties, either actively helping one of the two combatants or meditating such action Nor was the movement confined within even the widest limits of Hellas; the "barbarian" world also was affected by it—the non-Hellenic populations of Thrace, Macedonia, Epirus, Sicily and, finally, the Persian kingdom itself The aim of Thucydides was to preserve an accurate record of this war, not only in view of the intrinsic interest and importance of the facts, but also in order that these facts might be permanent sources of political teaching to posterity. His hope was, as he says, that his *History* would be found profitable by "those who desire an exact knowledge of the past as a key to the future, which in all probability will repeat or resemble the past The work is meant to be a possession for ever, not the rhetorical triumph of an hour." As this context shows, the oft-quoted phrase, "a possession for ever," had, in its author's meaning, a more definite import than any mere anticipation of abiding fame for his *History* It referred to the permanent value of the lessons which his *History* contained

Such being the spirit in which he approached his task, it is interesting to enquire what were the points which he himself considered to be distinctive in his method of executing it His Greek predecessors in the recording of events had been, he conceived, of two classes First, there were the epic poets, with Homer at their head, whose characteristic tendency, in the eyes of Thucydides, is to exaggerate the greatness or splendour of things past Secondly, there were the Ionian prose writers whom he calls "chroniclers" (*see* Logographi), whose general object was to diffuse a knowledge of legends, preserved by oral tradition, and of written documents (usually lists of officials or genealogies) preserved in public archives; and they published their materials as they found them, without criticism Thucydides describes their work by the word ξυντιθέναι but his own by ξυγγράφειν—the difference between the terms answering to that between compilation of a somewhat mechanical kind and historical composition, in a higher sense The vice of the "chroniclers," in his view, is that they cared only for popularity, and took no pains to make their narratives trustworthy Herodotus was presumably regarded by him as in the same general category

In contrast with these predecessors Thucydides has subjected his materials to the most searching scrutiny The ruling principle of his work has been strict adherence to carefully verified facts "As to the deeds done in the war, I have not thought myself at liberty to record them on hearsay from the first informant or on arbitrary conjecture My account rests either on personal knowledge or on the closest possible scrutiny of each statement made by others The process of research was laborious, because conflicting accounts were given by those who had witnessed the several events, as partiality swayed or memory served them"

The Speeches—It might be supposed that the speeches which Thucydides has introduced into his *History* conflict with this standard of scientific accuracy; it is, therefore, well to consider their nature and purpose rather closely The speeches constitute between a fourth and a fifth part of the *History* If they were eliminated, an admirable narrative would indeed remain, with a few comments, usually brief, on the more striking characters and events But we should lose all the most vivid light on the inner workings of the Greek political mind, on the motives of the actors and the arguments which they used—in a word, on the whole play of contemporary feeling and opinion To the speeches is due in no small measure the imperishable intellectual interest of the *History*, since it is chiefly by the speeches that the facts of the Peloponnesian War are so lit up with keen thought as to become illustrations of general laws, and to acquire a permanent suggestiveness for the student of politics When Herodotus made his persons hold conversations or deliver speeches, he was following the precedent of epic poetry; his tone is usually colloquial rather

than rhetorical; he is merely making thought and motive vivid in the way natural to a simple age. Thucydides is the real founder of the tradition by which historians were so long held to be warranted in introducing set speeches of their own composition. His own account of his practice is given in the following words: "As to the speeches made on the eve of the war, or in its course, I have found it difficult to retain a memory of the precise words which I had heard spoken; and so it was with those who brought me reports But I have made the persons say what it seemed to me most opportune for them to say in view of each situation; at the same time I have adhered as closely as possible to the general sense of what was actually said" So far as the language of the speeches is concerned, then, Thucydides plainly avows that it is mainly or wholly his own. As a general rule, there is little attempt to mark different styles The case of Pericles, whom Thucydides must have repeatedly heard, is probably an exception: the Thucydidean speeches of Pericles offer several examples of that bold imagery which Aristotle and Plutarch agree in ascribing to him, while the "Funeral Oration," especially, has a certain majesty of rhythm, a certain union of impetuous movement with lofty grandeur, which the historian has given to no other speaker Such strongly marked characteristics as the curt bluntness of the Spartan ephor Sthenelaidas, or the insolent vehemence of Alcibiades, are also indicated. But the dramatic truth of the speeches generally resides in the matter, not in the form. In regard to those speeches which were delivered at Athens before his banishment in 424 (and seven such speeches are contained in the *History*) Thucydides could rely either on his own recollection or on the sources accessible to a resident citizen In these cases there is good reason to believe that he has reproduced the substance of what was actually said In other cases he had to trust to more or less imperfect reports of the "general sense"; and in some instances, no doubt, the speech represents simply his own conception of what it would have been "most opportune" to say. The most evident of such instances occur in the addresses of leaders to their troops. The historian's aim in these military harangues (which are usually short) is to bring out the points of a strategical situation; a modern writer would have attained the object by comments prefixed or subjoined to his account of the battle The comparative indifference of Thucydides to dramatic verisimilitude in these military orations is curiously shown by the fact that the speech of the general on the one side is sometimes as distinctly a reply to the speech of the general on the other as if they had been delivered in debate. We may be sure, however, that, wherever Thucydides had any authentic clue to the actual tenor of a speech, he preferred to follow that clue rather than to draw on his own invention Why, however, did he not content himself with simply stating in his own person, the arguments and opinions which he conceived to have been prevalent? The question must be viewed from the standpoint of a Greek in the 5th century B C Epic poetry had then for many generations exercised a powerful influence over the Greek mind. Homer had accustomed Greeks to look for two elements in any complete expression of human energy—first, an account of a man's deeds, then an image of his mind in the report of his words. The Homeric heroes are exhibited both in action and in speech Further, the contemporary readers of Thucydides were men habituated to a civic life in which public speech played an all-important part. Every adult citizen of a Greek democracy was a member of the assembly which debated and decided great issues. The law courts, the festivals, the drama, the market-place itself, ministered to the Greek love of animated description. To a Greek of that age a written history of political events would have seemed strangely insipid if speech "in the first person," had been absent from it, especially if it did not offer some mirror of those debates which were inseparably associated with the central interests and the decisive moments of political life. In making historical persons say what they might have said, Thucydides confined that oratorical licence to the purpose which is its best justification; with him it is strictly dramatic, an aid to the complete presentment of action, by the vivid expression of ideas and arguments which were really current at the time. Among later historians who continued the practice, Polybius, Sallust and Tacitus most resemble Thucydides in this particular

Divisions of the Book.—The present division of the *History* into eight books is one which might well have proceeded from the author himself, as being a natural and convenient disposition of the contents. The first book, after a general introduction, sets forth the causes of the Peloponnesian War. The first nine years of the war are contained in the second, third and fourth books —three years in each The fifth book contains the tenth year, followed by the interval of the "insecure peace." The Sicilian expedition fills the sixth and seventh books The eighth book opens that last chapter of the struggle which is known as the "Decelean" or "Ionian" War, and breaks off abruptly in the year 411.

The principal reason against believing that the division into eight books was made by Thucydides himself is the fact that a different division, into 13 books, was also current in antiquity, as appears from Marcellinus (§ 58) It is very improbable (indeed hardly conceivable) that this should have been the case if the eight-book division had come down from the hand of the author We may infer, then, that the division of the work into eight books was introduced at Alexandria—perhaps in the 3rd or 2nd century B C That division was already familiar to the grammarians of the Augustan age. Dionysius of Halicarnassus, who recognizes it, has also another mode of indicating portions of the work, viz, by *stichometria,* or the number of lines which they contained Thus, in the ms which he used, the first 87 chapters of book i contained about 2,000 lines (equivalent to about 1,700 lines in Bekker's stereotyped 8vo. text). (On the order of composition, *see* PELOPONNESIAN WAR, *ad init*; and GREECE: *Ancient History,* § Authorities)

The division of the war by summer and winter (κατὰ θέρος καὶ χειμῶνα)—the end of the winter being considered as the end of the year—is perhaps the only one which Thucydides himself used, for there is no indication that he made any division of the *History* into books. His "summer" includes spring and autumn and extends, generally speaking, from March or the beginning of April to the end of October His "winter" (November to February inclusive) means practically the period during which military operations, by land and sea, are wholly or partly suspended When he speaks of "summer" and "winter" as answering respectively to "half" the year (v. 20, 3), the phrase is not to be pressed; it means merely that he divides his year into these two parts The mode of reckoning is essentially a rough one, and is not to be viewed as if the commencement of summer or of winter could be precisely fixed to constant dates. For chronology, besides the festivals, he uses the Athenian list of archons, the Spartan list of ephors and the Argive list of priestesses of Hera

There is no reference to the *History* of Thucydides in the extant Greek writers of the 4th century B.C.; but Lucian has preserved a tradition of the enthusiasm with which it was studied by Demosthenes. The great orator is said to have copied it out eight times, or even to have learnt it by heart. The Alexandrian critics acknowledged Thucydides as a great master of Attic Sallust, Cornelius Nepos, Cicero and Quintilian are among the Roman writers whose admiration for him can be traced in their work, or has been expressly recorded. The most elaborate ancient criticism on the diction and composition of Thucydides is contained in three essays by Dionysius of Halicarnassus.

BIBLIOGRAPHY—Among the best mss. of Thucydides, the Codex Vaticanus 126 (11th century) represents a recension made in the Alexandrian or Roman age. In the first six books the number of passages in which the Vaticanus alone has preserved a true reading is comparatively small; in book vii. it is somewhat larger; in book viii. it is so large that here the Vaticanus, as compared with the other mss., acquires the character of a revised text. Other important mss. are the Palatinus 252 (11th century); the Casselanus (A D. 1252); The Augustanus Monacensis 430 (A.D. 1301). A collation, in books i., ii., of two Cambridge mss. of the 15th century (NN. 3, 18; KK. 5, 19) has been published by Shilleto. Several Parisian mss. (H. C. A. F.) and a Venetian mss. (V.) collated by Arnold, also deserve mention. The Aldine ed. was pub. in 1502. It was formerly supposed that there had been two Juntine eds. Shilleto, in the "Notice" prefixed to bk. i, first pointed out that the only Juntine ed. was that of 1526, and that the belief in an earlier Juntine of 1506, arose merely from the accidental omission of the word *vicesimo* in the Latin

version of the imprint. Some papyrus fragments were published in Grenfell and Hunt's *Oxyrhynchus papyri* (1908), vi., which also contains an anonymous commentary (pub. 1st century) on Thuc. ii. A useful ed. is Classen's, in the Weidmann series (1862–78, new ed. by Steup, 1882–92); each book can be obtained separately. Arnold's ed. (1848–51) contains much that is still valuable. For bks. i. and ii. Shilleto's ed. (1872–76) furnishes a commentary which, though not full, deals admirably with many difficult points. Among other important complete eds., it is enough to name those of Duker, Bekker, Goeller, Poppo and Krüger. For eds. of separate books and selections (up to 1895) *see* J. B Mayor's *Guide to the Choice of Classical Books.* Special mention may be made of those by E. C. Marchant. Later eds. of the text are by H Stuart Jones (1900–01), in the Oxford *Scriptorum classicorum bibliotheca,* and C. Hude ("Teubner Series," 1901; ed. minor, 1903). Bétant's lexicon to Thucydides (1843) is well executed. Jowett's trans. (1883) is supplemented by a vol. of notes. Dale's version (Bohn) also deserves mention for its fidelity, as Crawley's (1876) for its vigour. *Thucydides and the History of His Age* by G. B. Grundy, discusses various general questions connected with the history of the time, and has a long summary of the controversy on the mode and times in which the historian composed his work. *Hellenica* (1880) contains an essay on "The Speeches of Thucydides," which has been trans. into German (*see* Eduard Meyer, *Forschungen zur alten Geschichte* Bd. ii. pp. 269–436). The best clue to Thucydidean bibl. is in Engelmann's *Scriptores graeci* (1880), supp. by the arts by G Meyer, in Bursian's *Jahresbericht* (1895) lxxix., (1897) lxxxviii. Busolt, *Griechische Geschichte,* iii. 616–693, is invaluable. For the life of Thucydides, U. von Wilamowitz-Moellendorff, "Die Thukydides-Legende," *Hermes* (1878) xii., is all important All works on ancient Greek history contain discussions of Thucydides, and see J B Bury's *Anc Greek Historians* (1909) and *Cambridge Anc History,* vol iv and v (1926–27) (R C J , X)

THUGGA (mod Dougga), an ancient city of North Africa, lying on a commanding site about 1 m. W. of the military road from Carthage to Tebessa (68 m by road S W. of Tunis) Its importance dates from Punic times, and it appears to have been taken from Carthage by the Numidian king Masinissa in the 2nd century B C Its most important buildings date from *c.* A D 150–250 and it only became a municipality under Septimius Severus, and a colony even later The well preserved Capitolium, or Temple of Jupiter, Juno and Minerva, built by Marcus Aurelius, occupies the finest position in the city; to the west of it lies the forum, and to the east the Temple of Mercury West of the forum, which is surrounded by fortifications of the Byzantine period, lies the beautiful crescent-shaped Temple of Caelestis, the Phoenician Tanit, built in the time of Alexander Severus.

To the north-east of the forum is a well preserved theatre, built in A D 166–169, with a splendid view over the surrounding country. To the north is a large temple of Saturn (A D 195), the Romanized form of Baal-Hammon, with six large columns, and close to it is a small Christian church; while to the west lie the remains of what may have been the pre-Roman acropolis, with native tombs, dolmenic in form, beyond it, and further on again are the remains of a circus. To the south-east of the forum, built against the hill side, is a group of interesting private houses decorated with mosaics and fountains.

THUGS, a well-organized confederacy of professional assassins, who travelled in gangs through India, wormed themselves into the confidence of wayfarers and, when a favourable opportunity occurred, strangled them by throwing a handkerchief or noose round their necks, and then plundered and buried them (Sanskrit *sthag,* to conceal, hence *sthaga,* a cheat, in modern vernaculars *thag*). All this was done according to certain ancient and rigidly prescribed forms and after the performance of special religious rites, in which the consecration of the pickaxe and the sacrifice of sugar formed a prominent part. From their using the noose they were also frequently called *Phansigars,* or "noose-operators." Though they themselves traced their origin to seven Mohammedan tribes, Hindus appear to have been associated with them at an early period; at any rate, their religious creed and practices as staunch worshippers of Kali (Devi, Durga), the Hindu goddess of destruction, had certainly no flavour of Islam. The fraternity possessed also a jargon of their own (*Ramasi*), as well as certain signs by which its members recognized each other.

Though sporadic efforts were made towards the extinction of the gangs, it was not till Lord W. Bentinck (1828–35) took vigorous steps that the system was seriously attacked. His chief agent, Captain (afterwards, Sir William) Sleeman, with the co-operation of a number of native states, succeeded so well in grappling with the evil that, up to Oct. 1835, no fewer than 1,562 Thugs had been committed, of whom 382 were hanged and 986 transported or imprisoned for life. According to the *Thuggee and Dacoity Report* for 1879, the number of registered Punjabi and Hindustani Thugs then still amounted to 344; but all of these had already been registered as such before 1852, and the whole fraternity may now be considered as extinct.

Full particulars concerning the system of Thagi are given by Dr. Sherwood, *On the Murderers called Phansigars,* and J. Shakespear, *Observations regarding Budheks and Thegs* (both treatises in vol xiii. (1820), of the *Asiatic Researches*); W. N Sleeman, *Ramaseeana, or a Vocabulary of the Language used by the Thugs, with an Introduction and Appendix* (Calcutta, 1836); Meadows Taylor, *Confessions of a Thug* (1839; new ed. 1879).

THUGUT, JOHANN AMADEUS FRANCIS DE PAULA, Baron (1736–1818), Austrian diplomatist, was born at Linz on May 24, 1736. In 1769 he was appointed chargé d'affaires at Constantinople, and in that capacity secured a grant of money and a promise of the territory of Little Wallachia from the Turks during the negotiations connected with the first partition of Poland. (*See* Poland· *History.*) In 1771 he was ennobled and appointed internuncio at Constantinople and was actively engaged, under the direction of Prince Kaunitz, in all the diplomacy of Austria in Turkey and Poland until he secured the cession of the Bukovina on May 7, 1775.

After 1775 Thugut travelled in France and Italy, partly on diplomatic service In 1778 he acted as intermediary in Maria Theresa's negotiations with Frederick the Great In 1780 he was Austrian envoy in Warsaw, but in 1783 applied for leave and spent four years in Paris, where he invested his savings and became acquainted with many of the leaders in the Revolution. From 1787 to 1789 he was minister at Naples In 1790 he was sent by the emperor Joseph II to Bucharest, nominally as commissioner with the hospodar of Wallachia, but in reality in order that he might open negotiations for peace with the Turks In 1792 he was associate diplomatic agent at the headquarters of the allied army which invaded France, and was then appointed "director of the foreign affairs of Austria" (March 25, 1793), becoming chancellor in 1794, on the death of Kaunitz

The selfish policy which Thugut followed (1793–1800) in Austria was bitterly resented by her allies, and although Thugut probably thought that he was only doing his duty, he committed many acts which were more than dubious. After the defeats of Austria in Italy in 1796–97 and the Peace of Campo Formio, it became a fixed object with the French, and with a growing party in Austria who held him responsible for the disasters of the war, to secure Thugut's removal.

The battle of Hohenlinden (Dec. 3, 1800) made his position untenable He retired from public life, and left Vienna for Pressburg. He afterwards returned to Vienna and lived quietly on a pension of 7,000 florins till his death on May 28. 1818

THUILLE, LUDWIG (1861–1907), German composer, was born at Bozen (Bolzano) on Nov 30, 1861 After being taught by his father, an amateur, and by Pembour at Innsbruck, he went to Munich in 1879 to finish his studies under Barmen and Rheinberger In 1883 he was appointed professor at the Munich school of music, and while there became a close friend of Alexander Ritter and Richard Strauss. His first opera, *Theuerdank,* was produced in Munich in 1897; a second, *Lobetanz,* at Mannheim in 1898 and a third, *Gugeline,* at Bremen in 1901. Two interesting choral works are *Traumsommernacht,* for female voices, and *Weihnacht im Walde,* for men's chorus (op. 14) His chamber music includes a sextet, op. 6, for piano and wind instruments (1887) and a violoncello sonata.

See Friedrich Munter, *Ludwig Thuille* (Munich, 1923).

THULE (thōō'lē), Greek and Roman name for the most northerly known land in the Atlantic. Pytheas (*c.* 300 B.C.) calls it the most northerly of the British Isles, reached after 6 days' sail from Britain; it was inhabited, but corn grew there sparingly and ripened ill; in summer the nights were long and bright. The few surviving fragments of his works do not determine where his Thule was, but Müllenhoff is probably right in thinking it

was the Shetlands The Faeroes, Iceland and Norway are much less likely Agricola's fleet in A.D 84 sailing up the east coast of Scotland is said to have espied but not to have reached Thule (*dispecta est Thule*) but the phrase is merely literary. The actual point meant may be the Orkneys or the Shetlands, or even some fragment of Scotland seen across the water. In some later writers (Procopius, etc) Thule seems sometimes used to denote Scandinavia The phrase "ultima Thule" is commonly used to describe the farthest limit possible.

THULIUM, a very rare metallic element (symbol Tm, atomic number 69, atomic weight 169 4) of the rare-earth group, was discovered by Cleve in 1879 while examining crude erbium oxide It was first obtained in the form of a pure compound by C James in 1911 by the fractional crystallization of its bromate Thulium occurs to a very slight extent along with its commoner associates in the minerals gadolinite, euxenite, xenotime, etc. Very large quantities of the minerals must be employed to obtain a little pure salt. The oxide, of a greenish-white colour, gives a beautiful carmine glow when gently heated in the Bunsen burner Salts of thulium possess a pale green colour and solutions show a very characteristic absorption spectrum. (*See* RARE EARTHS) (C J)

THUN, a picturesque town in the Swiss canton of Bern, built on the banks of the Aar, just as it issues from the Lake of Thun, and by rail 19 m S E of Bern Its population in 1920 was 14,162, mostly German-speaking and Protestants, in 1928 (Jan. 1st) it was estimated at 18 450 From 1798 to 1802 Thun was the capital of the canton Oberland of the Helvetic Republic. It is now the capital of the Bernese Oberland

THUN, LAKE OF, in the Swiss canton of Bern, the second lake (the first being that of Brienz) into which the river Aar (*q v*) expands. These two lakes occupy an ancient terminal basin of a glacier and are separated by a lacustrine delta on which Interlaken stands. Lake Thun (with the town of Thun at its north-western end) is 11½ m. long, 2 m. wide, its maximum depth is 712 ft, while its area is 18½ sq m, and its altitude 1,837 ft

THUNDER, the noise which accompanies or follows a flash of lightning (*q v*), on account of the air disturbance caused by the sudden heating and expansion of air during the electrical discharge (*See* ATMOSPHERIC ELECTRICITY and METEOROLOGY.)

THUNDERSTORMS. Since the middle of the 18th century it has been realized that lightning is an electric spark, and that thunder is the noise produced by the spark The natural tendency was to assume that the meteorological phenomena of the thunderstorm, and especially the heavy rainfall, were produced by electricity The modern view is that the rainstorm is the primary phenomenon and that the electricity is incidental.

AS METEOROLOGICAL PHENOMENA

The common feature of thunderstorms is their great vertical extent. The base of a cloud may be between 1 and 2 km. above the ground The summit may reach the level of the cirrus clouds, at a height of 9 km. or more

To explain the motive power required for the production of such a cloud we must consider the behaviour of dry air and moist air when subject to changes of pressure. Air is heated by compression and cooled by expansion If, however, the air contains drops of water, the rise of temperature causes evaporation, and some of the energy used in compressing the air is converted into latent heat The same increase of pressure produces less rise of temperature in wet air than in dry air Conversely, the expansion of saturated air in which condensation is taking place will be accompanied by a smaller fall of temperature than the expansion of dry air Further, if two masses of air have the same temperature initially, and both are cooled by the reduction of pressure, the wet air will not only be the warmer at the end of the process but will also be lighter, and occupy more space. In the atmosphere, where masses of air can move freely, those masses which contain cloud tend, on the whole, to be the more buoyant. Thus we have a general explanation of the formation of cumulus cloud. The air in the lower part of the atmosphere is warm, and contains water in the form of vapour. If some of this air is carried upwards to a level where the pressure is lower, the temperature falls, and at a certain height condensation begins. The air brought from below may be at the same temperature as the surrounding air at this height, but as condensation proceeds the rising air remains comparatively warm, and it may be lighter than its surroundings. A cloud has begun to form, and, as the top of the cloud rises, air from below takes its place, and the cloud tends to grow The conditions favourable for the growth of a cumulus cloud are. (1) The upper air into which the cloud grows is cold, preferably with a lapse rate approaching the limiting value 10° C per kilometer (2) The lower air contains much water vapour, and is not too stable; if vigorous convection is taking place, the lapse rate in this lower air may even exceed 10° C per kilometer By the time the cloud has grown to a height of some kilometers, the difference between the pressure at the bottom of the cloud and at other points at the same level will be very great, and the upflow of air through the cloud very violent In the rising air condensation proceeds rapidly. Some of the drops are carried up by the air They are frozen to form soft hail, and then covered by more ice to become true hail. The raindrops or hailstones get thrown out of the more vigorous ascending currents and are able to fall through and out of the clouds

Experience shows that these are the circumstances in which the electrical phenomena which characterize thunderstorms occur According to some observers there is no true thunderstorm without the formation of false cirrus at the top of the cloud In the early stages of growth the air surrounding the top of a cloud is comparatively dry, and the parts of the cloud carried away by eddies re-evaporate When the cloud towers up to the cirrus level, where the temperature is so low that very little moisture can be held in the gaseous state, evaporation can no longer take place at the top of the cloud, and when the ascending air mixes with the other air of that height, numerous ice crystals build up the cap of false cirrus.

Types of Thunderstorms.—Thunderstorms can be divided into four classes:—

(*a*) *Storms Produced in Air Which Is More or Less Stationary* —The condition for the production of these storms is the development of instability by the warming of the ground; water evaporated from the ground and from vegetation is carried up by the convection currents to the level at which condensation takes place If the air originally above this level is cold enough, the lapse of temperature being greater than in a nascent cloud, these thunder clouds will develop freely

(*b*) *Storms Produced in Air Which Has Travelled from a Colder Region to a Warmer* —When air flows over warm ground or warm water, heat may be communicated to the air sufficiently rapidly for the stratification to become unstable Under these conditions, thunder showers develop. They are usually of small extent.

(*c*) *Storms Produced by the Interaction of Converging Air Currents* —When a current of cold air meets a current of warm air, the warmer air, being lighter, is forced upwards. As the warm air reaches the condensation level, cloud is formed, and if conditions are favourable the clouds tower upwards so that the passage of the "cold front" is marked by a brief thunderstorm.

(*d*) *Storms Produced by the Interaction of Parallel Currents.*—If the general distribution of pressure is such that a current of polar air flows alongside a current of warmer air, a travelling area of instability is produced. Thunderstorms of great intensity develop and may extend for a hundred miles or more in the direction of the currents

The Distribution of Thunderstorms.—The storms of class (*a*) are most frequent in the Tropics; they occur also in summer in the temperate zone. These storms show a well-marked diurnal variation, they develop generally during the afternoon.

The storms of class (*b*) are characteristic of the rear of barometric depressions, and occur over the sea, in winter, when air from high latitudes is blowing over comparatively warm water. On the western coasts of the British Isles such storms are not infrequent The storms which occur at night on certain coasts in the Tropics, when the off-shore breezes set in, may also be included in class (*b*).

The "cold-front" storms of class (*c*) are met with in the tem-

perate zone. They are associated with line-squalls. The progress of a cold-front and its attendant thunderstorms can sometimes be followed for hundreds of miles by observers of "atmospherics."

Thunderstorms are most frequent in the Tropics. The average number of days in which thunder is reported, annually, is as high as 143 at Leon, in Mexico, and 133 at Batavia, in Java On the other hand, in the desert countries thunderstorms are almost unknown. They are rare in high latitudes For numerous land stations in the Northern Hemisphere, Brooks has computed the annual average of 25; for the land of the Southern Hemisphere (excluding Antarctica), the average is 44. His estimate for the whole globe, land and sea, is 16 As in all such statistics, the number is intended to refer to the number of days on which thunder is audible at any time.

In many parts of the world thunderstorms are not most frequent in summer because that is a dry season This is the case in Mediterranean countries. At Barcelona and at Rome, thunderstorms are most common in September. Similar influences are felt in Switzerland, where thunderstorms are less frequent at the end of June than at its beginning, or in the last part of July

AS ELECTRICAL PHENOMENA

To the eye, a lightning flash is instantaneous, and it cannot be seen whether it begins at one end or the other. It is clear, however, that the resistance of the air to the electric stress must break down, in the first instance, at one definite point The air at this point is ionized and becomes a conductor, and the greatest electric stress is transferred to a neighbouring point. The discharge is therefore progressive From theoretical considerations and from laboratory experiments, G C Simpson has proved that such a progressive discharge always proceeds from a positively charged body towards a negatively charged body The spark is frequently branched, and it is the rule for the branches to lead away from the positively charged body When a branched lightning flash is seen, the direction in which electricity is passing can, therefore, be stated

The absence of branches indicates that the flash has passed from a positive charge spread over a wide area to a more concentrated negative charge Simpson classified numerous photographs of lightning, amongst which were 418 flashes which appeared to be approximately vertical In 242 of these flashes there were branches pointing downwards; in only three were branches pointing upwards In the former cases the clouds from which the lightning proceeded must have been positively charged, in the latter cases the cloud must have been negatively charged Even if negatively charged clouds preponderated in the cases in which the flashes were unbranched, the positively charged clouds were in the majority

The colour of lightning flashes varies considerably According to Trabert's observations at the mountain station on the Sonnblick, where the electric field during a thunderstorm is so strong that brilliant St Elmo's fire can be observed, blue lightning is to be seen when negative electricity is being discharged by St Elmo's fire, and red lightning is associated with the positive discharge It may be noted that the difference between the types of St Elmo's fire is striking The negative fire is concentrated; an object like a flagstaff may be completely enveloped in fire. On the other hand, the positive fire takes the form of streamers, some as much as 10 cm long.

The quantity of electricity which is transferred in a lightning flash can be estimated from the change which occurs in the electric field near the ground. The quantity is generally between 10 and 50 coulombs As the discharge takes about one-thousandth of a second to pass, the maximum current is comparable with 50,000 amperes. The difference of potential between the cloud and the earth before the discharge is of the order 10^9 volts. The energy dissipated by the discharge of 20 coulombs through such a voltage is 10^{10} joules, or about 3,000 kilowatt hours. This energy would suffice to lift 500 tons through 2 kilometers.

The Electrical Structure of a Thundercloud.—As to what should be regarded as the typical distribution of electricity in a thundercloud, agreement has not yet been reached. The majority of investigators favour the view that, in general, the positive charges are at greater heights than the negative

When a lightning discharge occurs there is an immediate change in the electric force. The change is appreciable even at distances of 100 m. or more In the case of nearby disturbances, there is in the interpretation of the observations some ambiguity. This disappears, however, when the distance of the electric charges is great compared with their height. In a series of observations made at Khartum on April 23, 1924, and lasting four-and-a-quarter hours, the appearance of lightning estimated at between 30 and 300 km away was noted at the same time as changes in the electric field. There were 37 discharges accompanied by a descent of negative electricity, and 444 accompanied by a descent of positive electricity. With regard to the discharges of the former type, it was observed: (1) That they appeared to reach the earth, whereas the others appeared to be in the clouds; (2) that they were of greater brilliance; (3) that the illumination from the lightning lasted longer (as long as three seconds)

Some observations seem to imply that, throughout the storm a structure is being built up continuously in which there is a positive charge high in the cloud and a negative charge near the base. According to this view, the majority of flashes pass between the upper and lower charged regions, the minority between the lower charged region and the earth Simpson maintains, however, that the downward discharges of positive electricity do not originate very high in the cloud He believes that many of these discharges terminate in the free air below the cloud The most direct evidence in favour of this view is the frequency with which branching discharges occur in photographs.

The Electric Field Near Thunderstorms. *Discharges from the Earth*—The interchange of electricity between the ground and the atmosphere is carried on, to a large extent, by the discharges from pointed objects. When a pointed object stands up high above its surroundings, the discharge seen after dark is luminous, and is then known as St. Elmo's fire.

Measurements of the strength of the discharges from pointed objects have been undertaken Wormell, working at Cambridge, used a single point 8·3 metres above the ground Schonland, in South Africa, used a small tree, the top of which was 4 metres above the ground The largest discharge recorded by Wormell in a single shower was 30 millicoulombs, Since the electricity displaced in a single lightning flash is of the order 30 coulombs, we may say that the current from a thousand such points would provide enough electricity to make a flash

Schonland gives the following table, showing the relation between the strength of the electric field over level ground and the current passing through his tree

Field (volts per metre)	3,500	5,500	11,000	16,000
Current (microamperes)	·07	·20	1·00	4·00

It will be seen that the current increases much more rapidly than the field This is in accordance with other observations of the discharge from points.

The Electrification of Rain.—The electric charge carried by rain can be positive or negative. Moreover, either sign can occur with a positive potential gradient, and equally with a negative potential gradient According to Gschwend, the charge on individual raindrops varies between ·005 and 1 electrostatic units On the whole, the positive charges predominate This is especially the case in heavy rain In Simla, Simpson found the ratio of the total positive charge to the total negative charge brought down by rain was 2·9 For Potsdam, the corresponding ratio is given by Kähler as 1·4 The highest charge measured at Potsdam was 40 electrostatic units per cubic centimetre

The Net Displacement of Electricity.—Schonland compares the discharge from points with the quantity of electricity carried from earth to cloud by lightning and by charged rain The total current for the whole area affected by a thundercloud is made up as follows: Point discharges 2·1 ampere. Lightning discharges 0·1 ampere. Charged rain—·02 amperes; total about 2·2 amperes.

The observations confirm Wilson's remark that "of the three kinds of electric current which may accompany precipitation, the convection current of lightning discharges and continuous currents

due to the intense electric fields, it is quite possibly the last which contributes most to the interchange of electricity between the earth and the atmosphere." The thunderstorms studied by Schonland produced little rainfall, but the preponderance of positively charged rain in his experiments is consistent with general experience. If the rainfall over the area of his hypothetical storm, 20 km.^{2}, had been at the rate appropriate to heavy thunderstorms, say 1 mm. per minute, and if the rain had been highly charged so as to carry four electrostatic units per cubic centimetre of water, the average current would have been of the order 0.4 amperes. Other observers have found strong positive gradients as frequent as strong negative ones during storms.

If the conclusions of Schonland can be accepted as generally true, it will follow that the net flow of positive electricity from ground to atmosphere in thunderstorms is adequate to supply the electricity needed to maintain the air-earth current over the parts of the globe enjoying fine weather. According to Wilson, positive electricity and negative are separated in the cloud, the positive charge being uppermost Between this upper charge and the Heaviside layer there is a conduction current, facilitated by the comparatively high conductivity of the air. The Heaviside layer may be regarded as a perfect conductor. The current between this layer and the ground in the fine-weather regions is downwards That there is such a connection as is postulated by Wilson is borne out by the striking agreement between the daily changes of potential gradient over the oceans and the variations in the number of thunderstorms which are likely to be in progress

Simpson's Theory of Thunderstorm Mechanism.—Of the explanations which have been suggested for the production of electrification in clouds, the only one which appears at all adequate is that proposed by G C. Simpson This theory is based on the observation that, when water-drops are broken by an air-blast the spray is electrified positively, the air negatively. In a cumulo-nimbus cloud there are regions in which the upward currents are powerful enough to prevent any rain falling through them. Simpson contends that such currents are so persistent that the water accumulates in them for several minutes As the raindrops are continually breaking up and recombining, they acquire large positive charges The air currents convey the negative charge to less turbulent regions, and the droplets which form in such regions become negatively charged Thus negatively charged rain is to be expected in the greater part of the cloud

Simpson has applied numerical tests to prove that the causes are adequate to produce the observed effects. In his typical thunderstorm, the region in which water accumulates is equivalent to a sphere 2 km in diameter, and is about one-hundredth part of the whole cloud It is supposed that, after a quarter-of-an-hour, there is enough water to make 10 cm. of rain on the ground immediately below. This estimate is arrived at by consideration of the volume of air carried up by a current of 8 metres per second, and of the amount of water vapour contained in the air at the temperatures prevailing at 2 km. and 4 km above the ground. The accumulated water is equivalent to 4.4×10^{12} drops 5 millimetres in diameter. If all these drops were broken into spray, about 7 coulombs of positive electricity would remain on the spray, and an equal quantity of negative electricity would be carried away by the air currents.

To explain the great strength of the electric field necessary to start a lightning flash, Simpson supposes that the density of the electric charge in one part of the region of separation is very great. A sphere 500 metres in diameter would occupy one sixty-fourth of the whole region in which electrification was taking place. If the water drops in the sphere were broken up 256 times a charge of 28 coulombs would be developed, and if the process took 4 minutes, the strong air-currents of 8 metres per second would remove the complementary negative charge to a distance averaging about a kilometre.

Now, 28 coulombs are rather less than the average quantity of electricity in a lightning discharge. Further, it is easily proved that the force due to the 28 coulombs in a sphere with diameter 500 metres is, at the surface of the sphere, equivalent to 4×10^6 volts per metre, and therefore sufficient to break down the resistance of the air and initiate a lightning flash. It is supposed that the lightning does not discharge the whole cloud.

The theory accounts for the flashes which convey positive electricity downwards from the lower part of the cloud towards the earth or upwards inside the cloud.

The lightning flashes by which positive electricity is conveyed upwards to the cloud, are thought by Simpson to be rather rare.

Criticisms of Simpson's Theory.—The theory is based on the observed facts that water drops which are uncharged or slightly charged, acquire positive charges when broken up, and that charged drops, when they collide, will combine. There is, however, no experimental evidence that the processes of breakage and combination can be so active simultaneously that all the water passes through the two processes each second. Such a rate seems to be necessary to account for the frequency of lightning flashes Moreover, it is difficult to believe that the persistence for a quarter-of-an-hour of a vertical current localized in one small part of the cloud is an essential feature of a thunderstorm.

The theory has been attacked more generally on the ground that the natural interpretation of observations of the changes in the electric field in a storm is that the upper part of a thundercloud is usually the seat of a positive charge. Simpson's reply to this criticism is that the observations in question can be explained on the assumption that the most frequent discharges are those in which positive electricity is displaced from the region of separation inside the cloud to the air between the cloud and the ground To the criticism that observations such as those of Wormell and Schonland imply a great transfer of positive electricity from the ground upwards during a thunderstorm, Simpson's reply is that the observations are not representative, being taken under such circumstances that positive fields were exceptionally infrequent More observations are needed, especially in parts of the world where tropical storms occur.

The literature of thunderstorms is extensive. The following list is almost confined to works quoted in the foregoing article.

THURET, GUSTAVE ADOLPHE (1817–1875), French botanist, was born in Paris on May 23, 1817. He spent a great part of his time, up to 1857, on the Atlantic coast of France, assiduously observing the marine Algae in their natural habitat and at all seasons. He and his friend Édouard Bornet, became the recognized authorities on this group of plants. Their work, while remarkable for taxonomic accuracy, was more especially concentrated on the natural history, development and modes of reproduction of the plants investigated The discovery of sexual reproduction in seaweeds is almost wholly the work of these two men The researches on the fecundation of the Fucaceae were published by Thuret in 1853 and 1855; the complicated and difficult question of the sexual reproduction in Floridae was solved by the joint work of Thuret and Bornet (1867). These great discoveries—of far-reaching biological significance—stand out as the chief, but every group of marine Algae was elucidated by the researches of Thuret and his colleague The *Notes algologiques* (1876–1880), and the *Études phycologiques* (1878) were posthumously published. In 1857 Thuret removed to Antibes, where he established a botanic garden which became famous He died at Nice, on May 10, 1875.

See notices by Bornet in *Ann. des Sci. Nat.* (1876) and Farlow in *Journ. of Bot.* (1876).

THURGAU, a canton of north-east Switzerland, bordered by the Lake of Constance and, for a short distance, by the Rhine below the lake. It is in contact with Schaffhausen and Zürich to the west and St. Gall to the south. Thurgau is divided into three well-wooded hill masses running north-west to south-east by the middle course of the river Thur (rising in the Toggenburg, *q v*) and by its affluent, the Murg

The canton is traversed by the main railway line from Winterthur to Romanshorn (with branches to Constance, to the Toggenburg and to St Gall); another important line extends from Rorschach along the lake shore via Constance, thence to Schaffhausen. The canton is a highly prosperous agricultural area, and though termed the "garden and granary of Helvetia" it also possesses an important cotton-spinning, dyeing and printing industry Its estimated pop. in 1926 was 139,100 Of its pop in 1920, 131,815 were German-speaking, 3,187 Italian-speaking and 537 French-speaking, while there were 90,665 Protestants, 44,467 Catholics and 157 Jews Its capital is Frauenfeld (pop 8,711) on the Murg, other towns are Arbon (9,393), Kreuzlingen and Romanshorn (6,474), which is the chief lake port of the canton

History.—The Thurgau originally took in all the country, roughly speaking, between the Reuss, the Lake of Lucerne, the Rhine and the Lake of Constance, but many smaller districts (Zurichgau, Toggenburg, Appenzell, St. Gall) were gradually carved out of it, and the county was reduced to about the size of the present canton when in 1264 it passed by the gift of the last count of Kyburg to his nephew Rudolph of Habsburg, chosen emperor in 1273 In 1460–61 it was seized by the Confederates and henceforth it was ruled as a "subject district" by seven members of the League—Bern occupied in the west, not being admitted to a share in the government till 1712, after one of the wars of religion In 1499 the Confederation obtained from the emperor the supreme jurisdiction

In 1798 it became free, and was one of the 19 cantons of the Helvetic republic, being formally received (like the other "subject lands") as a full member of the Swiss Confederation in 1803 by the Act of Mediation The very advanced Cantonal Constitution dates to 1869 (*See* SWITZERLAND, *Administration*)

BIBLIOGRAPHY—J A Pupikofer, *Der Kanton Thurgau* (St. Gall and Bern, 1835), and *Geschichte des Thurgaus* (to 1830; 2nd ed., 1884–89), *Beitrage (Thurg) zur vaterland Geschichte* (published by the Cantonal Hist Soc; from 1861).

THURIBLE, the ecclesiastical term for a censer, a portable vessel in which burning incense (*q.v.*) can be carried The censer, to use the more general term, is a vessel which contains burning charcoal on which the aromatic substances to be burned are sprinkled The early Jewish portable censer would seem to have been a bowl with a handle, resembling a ladle. A similar form was used by the ancient Egyptians long prior to the Jewish use. The Greek and Roman censers (*θυμιατήριον* and *turibulum* or *thuribulum*) are of quite different shape. They are small portable braziers (*foculi*) of bronze or sometimes of silver and of highly ornate design.

The censers or thuribles in Christian usage have been specially adapted to be swung, though many early specimens of heavy weight were obviously not meant to be used in this way.

THURII or THURIUM, a city of Magna Graecia on the Gulf of Tarentum, near the site of the older Sybaris (*q.v*). It owed its origin to an attempt made in 452 B.C. by Sybarite exiles and their descendants to repeople their old home. The new settlement was crushed by Crotona, but the Athenians lent aid to the fugitives, and in 443 Pericles sent out to Thurii a mixed body of colonists from various parts of Greece, among whom were Herodotus and the orator Lysias. In 390 it was severely defeated by the Lucanians, and at length called in the help of the Romans against the Lucanians, and then in 282 against Tarentum. Thenceforward it was dependent, and in the Second Punic War it was depopulated and plundered by Hannibal (204). In 194 a Roman colony was founded, known for a time as Copiae, but afterwards as Thurii.

THURINGIA (Ger. Land Thüringen), a Republic and a component state of the German Republic It consists of the former Thuringian States of Saxe-Weimar-Eisenach, Saxe-Meiningen, Reuss, Saxe-Altenburg, Saxe-Gotha (Coburg having been merged with Bavaria), Schwarzburg-Rudolstadt, and Schwarzburg-Sondershausen, which decided in 1919 to combine into one State. They maintained their identity as administrative districts until April 1, 1923, but were then completely merged into Thuringia. The country falls into two main divisions: the southern division is bounded on the north and west by Prussia, on the east by Saxony and on the south by Bavaria, while the smaller northern division is surrounded by Prussia. Its total area is 4,540·5 sq m

A considerable part of the country is occupied by the picturesque, rounded hills of the Thuringian forest Among the chief elevations are the Beerberg (3,225 ft), the Schneekopf (3,179 ft.) and the Inselberg (2,957 ft), on the northern slopes of the Thuringian forest The Altenburg district in East Thuringia is traversed by the westerly offshoots of the Erzgebirge, while the Rhön mountains extend into West Thuringia The south-eastern portion of Thuringia belongs to the bleak, mountainous region of the Frankenwald and the Vogtland The principal river is the Saale, which runs in a north-westerly direction as far as Saalfeld, and then flows north-east by Rudolstadt and Jena. Among the other rivers are the Werra, Ilm, Gera, Unstrut, Elster, Weisse, Wipper, Helbe and Pleisse The district watered by the Pleisse contains some of the richest agricultural soil in Germany

Of the total area of Thuringia, about 44% is occupied by arable land, 33% by forest, and 10% by pasture land. The chief mineral resources of Thuringia are lignite (found mainly in the Altenburg district), and potash in the valley of the Werra and in the Sondershausen district Iron ore, marble, cobalt, copper, slates, chalk and basalt are also found, and there are salt works at Salzungen and Neusalza, and brine springs at Heinrichshall and elsewhere Among the principal industrial products of Thuringia are textiles, glass and porcelain, iron goods and machinery, paper and leather goods, musical instruments, beer, chemicals, wooden toys, etc The manufacture of toys and textile goods is largely carried on under the domestic system The optical instruments of Jena and the scientific instruments of Ilmenau are well known

In 1925 Thuringia had 1,624,675 inhabitants, or 357·8 to the sq m. The population is mainly Teutonic, but there is a Wendish or Slavonic element The population is 90% Protestant. The University of Jena is the chief centre for higher education.

The constitution of Thuringia dates from March 11, 1921. The Landtag consists of 72 members For administrative purposes the country is divided into 10 town and 15 country districts (Kreise), and one sub-district (Kreisabteilung) The capital is Weimar, but Gera and Jena are larger towns and Gotha, Eisenach, Altenburg and Greiz are also noteworthy

History.—In the 5th century the Thuringians lived between the Harz mountains and the Thuringian Forest They were tributary to Attila the Hun, under whom they served at the battle of Châlons in 451 In the 6th century they were conquered by the Franks and remained under the direct rule of the Frankish kings until 634, when King Dagobert I appointed Radulf duke of the Thuringians, under whom they became virtually independent They were again brought under Frankish rule by Charles Martel, who abolished the office of duke and divided the country among Frankish counts. About 804 Charlemagne, in order to defend the line of the Saale against the Slavs, founded the Thuringian mark In 849 King Louis the German recognized Tlakulf as duke and some of his successors bore the title of margrave until the death of Burkhard in 908, when the country was seized by Otto the Illustrious, duke of Saxony. Thuringia was retained by Otto's son and successor, Henry I. the Fowler

In the 11th century a new dominion was founded by Louis the Bearded, who by purchase, gift or marriage obtained several counties in Thuringia. These passed on his death in 1056 to his son Louis the Springer (d. 1123), who took part in the Saxon risings against the emperors Henry IV. and Henry V. His son Louis was appointed landgrave of Thuringia in 1130 by the emperor Lothair II.; by his marriage with Hedwig of Gudensberg in 1137 he obtained a large part of Hesse. Louis was succeeded in 1140 by his son Louis II the Hard, who married Judith, a sister

of the emperor Frederick I., and on his behalf took a leading part in the opposition to his powerful neighbour Henry the Lion, duke of Saxony. In 1172 he was succeeded by his son Louis III. the Pious He acquired the Saxon palatinate in 1179, on the death of Adalbert, count of Sommerschenburg, went to Italy to assist Frederick I. in 1157, joined in the war against Henry the Lion in 1180, and distinguished himself at the siege of Acre in the Third Crusade, on the return from which he died at Cyprus in 1190. He was succeeded by his brother Hermann I., during whose reign Thuringia suffered greatly from the war between Philip duke of Swabia and Otto of Brunswick The next landgrave (1217–27) was his son Louis IV., a celebrated figure in mediaeval German literature, who married St. Elizabeth, daughter of Andrew II, king of Hungary, and died at Otranto while accompanying the emperor Frederick II. on crusade The next ruler was Henry Raspe, who made himself regent on behalf of his nephew Hermann II from 1227 to 1238 and in 1241 succeeded his former ward as landgrave.

After a disputed succession to the landgraviate it fell in 1263, together with the Saxon palatinate, to Henry III. margrave of Meissen Two years later Henry apportioned Thuringia to his son Albert the Degenerate, who sold it in 1293 to the German king Adolph of Nassau for 12,000 marks of silver Albert's sons Frederick the Undaunted and Dietrich contested this transaction, and the attempts of Adolph and his successor Albert I to enforce it led to the infliction of great hardships upon the Thuringians Frederick defeated Albert decisively and in 1314 was formally invested with Thuringia by the emperor Henry VII His son Frederick II the Grave (1323–49) consolidated the power of his dynasty against rebellious vassals and the neighbouring counts of Weimar and Schwarzburg His son Frederick III the Strong (1349–81) and his grandson Balthasar (1381–1406) further extended their dominion by marriage and conquest, and the latter of these founded the university at Erfurt (1392). Balthasar's son, Frederick the Peaceful, became landgrave in 1406 but left the government largely to his father-in-law Gunther, count of Schwarzburg He died childless in 1440, and Thuringia then passed to the electoral dynasty of Saxony After a joint rule by Frederick II and his brother William, the latter in 1445 became sole landgrave as William III and died without sons in 1482. In 1485 his nephews and heirs Albert and Ernest made a division of their lands, and Thuringia was given to the Ernestine branch of the family of Wettin, with which its history down to 1918 is identified (*see* SAXONY)

THURLES, a town of Co. Tipperary, Ireland, on the Suir and on the main line of the Great Southern and Western railway, 87m S.W of Dublin Pop (1926) 4,796. Originally the town was called Durlas O'Fogarty In the 10th century it was the scene of a defeat of the Irish by the Danes. A preceptory was founded here by the Knights Templars, who held a 13th century castle, of which there are remains A castle was subsequently erected by James Butler, first lord palatine of Tipperary, of which the keep collapsed in 1868. The Cistercian abbey of Holy Cross stands 3½ m. S.W of the town It was founded by Donnell O'Brien (1168–94) Thurles is the seat of the Roman Catholic archdiocese of Cashel.

THURLOE, JOHN (1616–1668), English politician, son of Thomas Thurloe, rector of Abbot's Roding in Essex, was baptized on June 12, 1616 He studied law, entered the service of Oliver St John, through whose interest he was appointed a secretary to the parliamentary commissioners at Uxbridge in 1645; other employments followed. On March 29, 1652, he was appointed secretary to the council of state. His duties included the control of the intelligence department and of the posts, and his perfect system of collecting information and success in discovering the plans of the enemies of the administration astonished his contemporaries. In the parliaments of 1654 and of 1656 he represented Ely; he was appointed a member of Cromwell's second council in 1657.

After Oliver's death Thurloe supported Richard Cromwell's succession, and took part in the administration, sitting in the parliament of January 1659 as member for Cambridge University. Appointed secretary of state on Feb. 27, 1660, he appears to have steadily resisted the Restoration, and his promises of support to Hyde in April inspired little confidence On May 15, 1660, he was arrested on the charge of high treason, but was freed on June 29, subject to the obligation of attending the secretaries of state "for the service of the state whenever they should require." He subsequently wrote several papers on the subject of foreign affairs for Clarendon's information He died on Feb. 21, 1668.

His extensive correspondence, the originals of which are in the Bodleian Library at Oxford and the British Museum (*Add MSS* 4156, 4157, 4158), is one of the chief sources of information for the period A portion was published with a memoir by T Birch in 1742, and other correspondence is printed in R. Vaughan's *Protectorate of Oliver Cromwell* (1836).

THURLOW, EDWARD THURLOW, 1ST BARON (1731–1806), English lord chancellor, was born at Bracon Ash, in the county of Norfolk, on Dec. 9, 1731, the eldest son of the Rev Thomas Thurlow. He was educated at Canterbury Grammar school and Caius college, Cambridge, but went down without a degree. In 1754 he went on the western circuit and after a successful brush with Fletcher Norton his reputation rose. He took silk in 1761, and in 1768 became M.P. for Tavistock in the Tory interest. The next year he led for the plaintiff in the Douglas peerage case. In 1770 he was made solicitor-general, and supported the Government views against the rights of juries in libel cases (*R.* v. *Miller,* 20 *St. Tr.* 870) and the liberty of the press (16 *Parl. Hist.* 1144), in 1770, he became attorney-general Politically he was factious and violent, he was a venomous opponent of the American colonies, he made a savage speech in aggravation of punishment in the Horne Tooke case (20 St. Tr 777), and was opposed to all interference with the slave trade In 1778 he became lord chancellor with a peerage. His position in the Lords was almost autocratic, and he continued to oppose the reforming schemes of Burke. Under Rockingham and Shelburne he remained chancellor; under the coalition he worked in opposition for the king; got the India bill rejected; and returned to the woolsack under Pitt (1783) Finally he came out openly in opposition to the National Debt Redemption scheme Pitt then insisted on his dismissal (1792), and he retired with the title of Baron Thurlow of Thurlow. He continued to speak in the Lords till 1802 and died at Brighton on Sept. 12, 1806

Thurlow was a master of caustic wit, habitually displayed in profanity. His judicial and his ecclesiastical patronage were wisely exercised; he was the patron of Dr. Johnson and of Crabbe; and was the first to detect the great legal merits of Eldon. Thurlow's personal appearance was striking. His dark complexion, harsh but regular features, severe and dignified demeanour, piercing black eyes, and bushy eyebrows, doubtless contributed to his political eminence, and provoked the sarcasm of Fox that he *looked* wiser than any man ever *was*.

See Lord Campbell's *Lives of the Chancellors,* vii. 153–333; Foss's *Judges of England,* viii. 374–385; *Public Characters* (1798); *Notes and Queries,* 2nd series, vol. iii p. 283, 3rd series, vol. iii p 122, *Reports* of his decisions by Brown, Dickens and Vesey (Jun); Brougham's *Statesmen of the Time of George III.*

THURMAN, ALLEN GRANBERY (1813–1895), American jurist and statesman, was born at Lynchburg (Va.), on Nov. 13, 1813. In 1819 he removed with his parents to Chillicothe (O.), where he attended the local academy for two years, studied law in the office of his uncle, William Allen, and in 1835 was admitted to the bar, becoming his uncle's law partner. He began to take an active part in politics in 1844, and in 1845–47 was a Democratic representative in Congress, where he advocated the Wilmot Proviso.

He was Democratic candidate for governor of Ohio in 1867, and was defeated by Rutherford B. Hayes by a majority of less than 3,000 votes; but the Democrats gained a majority in both branches of the State legislature, and Thurman was elected to

the United States Senate, where he served from 1869 until 1881—during the 46th Congress (1879–81) as president *pro tempore.* Here he became the recognized Democratic leader and in 1879–81 was chairman of the judiciary committee. He introduced the Thurman bill, for which he was chiefly responsible, which became law in May, 1878, and readjusted the Government's relations with the bond-aided Pacific railways.

Thurman was a member of the electoral commission of 1877, and was one of the American delegates to the international monetary conference at Paris in 1881 In 1876, 1880 and 1884 he was a candidate for the presidential nomination, and in 1888 was nominated for vice-president on the ticket with Grover Cleveland, but was defeated in the election. He died at Columbus (O.), on Dec. 12, 1895.

THURSDAY ISLAND, a small island belonging to Queensland, Australia, situated 30 miles to the north-west of Cape York in Torres Straits. It has an excellent harbour (Port Kennedy) which is the centre for the pearl, etc, fleets of the north-east. (*See* AUSTRALIA. *Fisheries.*) Pop (1926) 1,700.

THURSO, burgh of barony, police burgh, parish and seaport of Caithness, Scotland Pop (1921), 3,039 It is situated at the mouth of the Thurso, on Thurso bay, 21 m N W of Wick, and 319 m N of Edinburgh, by rail, on a branch line of the L.M.S. railway from Georgemas junction, the most northerly town on the mainland of Scotland.

In Macdonald square there is a statue of Sir John Sinclair The town-hall contains a public library and museum, which possesses the geological and botanical specimens of Robert Dick (1811–1866), the "Thurso baker," and a collection of northern birds To the east is Thurso castle, home of the Ulbster branch of the Sinclairs, and near it is Harold's tower, built over the grave of Earl Harold, once owner of half of Caithness, and half of the Orkneys and Shetlands, who fell in battle with Earl Harold the Wicked in 1190 About three-quarters of a mile west stand the ruins of the bishop's palace, which was destroyed by fire in 1222 Thurso was the centre of the Norse power on the mainland when at its height under Thorfinn (1014), and afterwards till the battle of Largs (1263) Count Modach, nephew of King Duncan, quartered his army for a time at Thurso and despoiled it till he was surprised and slain by Thorfinn in 1040.

THURSTAN or TURSTIN (d. 1140), archbishop of York, was the son of a certain Anger, or Auger, prebendary of St Paul's, London, and a brother of Audoen (d. 1139), bishop of Evreux. He himself was a prebendary of St. Paul's, and was also a clerk in the service of William II and then of Henry I., who secured his election as archbishop of York in Aug 1114. He now entered upon the great controversy which occupied him during a large part of his subsequent life and made him for several years an exile from England Archbishop Ralph of Canterbury refused to consecrate him unless he made a profession of obedience to the southern see; this Thurstan refused and asked the king for permission to go to Rome to consult Pope Paschal II. Henry I. declined to allow him to make the journey, while Paschal declared against Archbishop Ralph At the Council of Salisbury in 1116 the English king ordered Thurstan to submit, but instead he resigned his archbishopric, although this did not take effect. The new pope, Gelasius II, and also his successor, Calixtus II., espoused the cause of the stubborn archbishop, and in Oct. 1119, he was consecrated by Calixtus at Reims

Enraged at this the king refused to allow Thurstan to enter England, and he remained for some time in the company of the pope At length, however, his friends succeeded in reconciling him with Henry, and, after serving the king in Normandy, he was recalled to England. In 1138 he made a truce at Roxburgh between England and Scotland, and took active part in gathering together the army which defeated the Scots at the Battle of the Standard in Aug. 1138. Early in 1140 he entered the order of the Cluniacs at Pontefract and here he died on Feb. 6, 1140. Thurstan displayed marked generosity toward the churches of his diocese during his bishopric and was also the founder of a number of religious houses.

See his life in the *Fasti eboracenses*, ed. J. Raine (1863)

THYLACINE or **TASMANIAN WOLF** (*Thylacinus cynocephalus*). The only living species of this genus, though smaller than a wolf, is the largest predaceous marsupial existing. Its remarkable resemblance to a dog or wolf is entirely due to convergent evolution It is confined to the island of Tasmania, although a closely allied species once inhabited the Australian mainland. (*See* MARSUPIALIA.)

THYMBRA, BATTLE OF. This battle of 546 B C. was the decisive act in Cyrus the Great's overthrow of Croesus, king of Lydia, which in turn led to his subjugation of Asia Minor, and thus brought the Persians in contact with the Greeks—with momentous consequences to both (*See* GRAECO-PERSIAN WARS) As described in Xenophon's *Cyropaedia* the battle is rather instructional than historical, yet even so of far-reaching historical importance For this projection on to an historical screen of Xenophon's conception of the "model" commander and the "model" battle, affected the course of many wars yet undreamt of It served as the foundation of the study and reflection of the great captains of antiquity—Scipio, for example, is said to have carried the *Cyropaedia* with him throughout his campaigns. And with the Renaissance, and the revival of Greek studies, it lightened afresh the path of the great captains of the 16th, 17th and 18th centuries. As pictured by Xenophon, Croesus draws up his army in the customary single line many ranks deep, while Cyrus forms his in a deep series of lines, each only a few deep, capable of mutual support and manoeuvre When Croesus uses his superiority of numbers to wheel inwards his far-stretching wings in order to crush Cyrus's wedge-like formation between them, Cyrus fends them off by lines of scythed chariots charging outwards, while his cavalry and camelry reserve attacks the flanks of the inwheeling Lydian wings Then under cover of a frontal chariot attack on Croesus's centre, a small picked reserve of horse and foot is hurled at the point where one of the enemy wings joins on to the centre This pierced, the cut off centre is "played on" by arrows and javelins until it surrenders

There is an extraordinary parallel between this sequence of action—distention of the enemy's line, dislocation of a joint, followed by a disruption which decides the issue—and the fundamentals of Napoleon's tactic more than 2,000 years later

See Herodotus, i 79–80; Xenophon, *Cyropaedia*

THYME. The genus *Thymus* (family Labiatae) comprises a number of fragrant aromatic undershrubs, with very small leaves and whorls of small, purple, honey-bearing flowers in the axils of the leaves or at the ends of the branches The common garden thyme, a native of the Mediterranean region, is *T. vulgaris;* the wild thyme of English banks is *T serpyllum*, now naturalized in eastern North America from Nova Scotia to Pennsylvania Marjoram (*Origanum*) is also closely allied All these plants are remarkable for their essential oil, from which thymol is produced.

THYMOL: *see* CAMPHORS

THYMUS: *see* DUCTLESS GLAND, LYMPHATIC SYSTEM, DISEASES OF

THYROID, in anatomy, a term applied (1) to the largest of the cartilages of the larynx (*see* RESPIRATORY SYSTEM), (2) to one of two arteries which lie near the thyroid cartilage and gland (*see* ARTERIES), and (3) to a vascular ductless gland, which rests on the larynx and upper part of the trachea In human beings two conditions may occur both the result of a lack of thyroid secretion, but differing according as the condition is congenital or has started in early life, *i.e*, cretinism (*q v*), or occurs later in life, *i.e*, myxoedema (*q v*) (*See* also DUCTLESS GLAND)

The thyroid gland is used in medicine in two forms *Thyroideum siccum* is a light, dull brown powder, prepared by drying the thyroid gland of a sheep Its chief constituent is a proteid known as thyreoglobulin, the active principle of which contains 9·3% of iodine and 0·5% of phosphorus, and is known as iodothyrin or thyroiodin The dried gland easily becomes damp and deteriorates. *Liquor thyroidei* is a pink turbid liquid made by macerating the fresh gland of a sheep with glycerin and phenol The active principle in pure form—thyroxin—was isolated in 1914 by E. C. Kendall at the Mayo Clinic, Rochester, Minnesota.

Thyroid gland administered to man increases the pulse rate, causes increased and enfeebled cardiac beat and leads to increased metabolism, consequently excess of urea, uric acid and phosphates are excreted in the urine; it therefore reduces the body weight. Glycosuria develops from the inability of the body to ingest glucose. Overdoses of thyroid cause rapid pulse, headache and vomiting, together with diarrhoea and pruritus, emaciation and weakness These symptoms are known as *thyroidism*

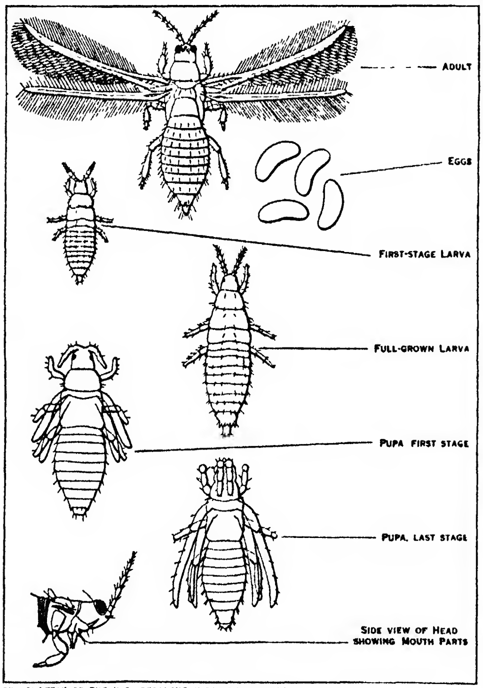
Thyroid gland was introduced for the treatment of goitre, myxoedema and cretinism (*q.v*). It has also been used in dwarfism, excessive obesity, psoriasis and scleroderma.

Rodagen is a white powder consisting of the dried milk of thyroidectomized goats, mixed with 50% of milk sugar In exophthalmic goitre this preparation causes a reduction of the swelling and of the pulse rate, and an increase of body weight

THYRSUS, a kind of staff carried by Dionysus (*q.v.*) and his votaries (Gr. θύρσος). It was a reed, sometimes having a spear-point at one end, topped with a pine-cone

See F. J. M. de Waele, *The Magic Staff or Rod* (1927).

THYSANOPTERA, the name used in zoological classification for a small order of the class Hexapoda commonly known as thrips The majority of these creatures are very small, varying in length from $\frac{1}{50}$ to $\frac{1}{3}$ of an inch, and they are mostly yellow, yellow-brown or black in colour. They are found among all kinds of growing vegetation—on the buds, flowers or foliage: others frequent decaying plant-remains especially wood and fungi. A small number are predators and suck the body fluids of aphides and Acari They are elongate, slender-bodied insects, with short six- to nine-jointed antennae, and asymmetrical piercing mouth-parts. The wings are very narrow and strap-like with greatly reduced venation and long fringes of marginal hairs. The tarsi are one- or two-jointed and the apex of each tarsus is terminated by a minute protrusible bladder or vesicle which enables them to climb almost any surface. The young forms closely resemble the adults in their general form and they ultimately pass into a resting stage or incipient pupa prior to becoming adults. Numerous thrips are wingless and some species consist of both winged and wingless individuals. Parthenogenesis is frequent in the order and males are either unknown, or very rare, in several species: in others the eggs are capable of developing parthenogenetically, although males are common.



BY COURTESY OF THE U S DEPARTMENT OF AGRICULTURE

LIFE HISTORY OF THE PEAR THRIPS (TAENIOTHRIPS PYRI)

Thysanoptera are divided into two sub-orders (1) *Terebrantia* in which the last segment of the abdomen is conical, that of the male being rounded, and the female has a saw-like ovipositor most of the species feed on living plants. (2) *Tubulifera* in which the last segment of the abdomen is tubular in both sexes and the female is without a saw-like ovipositor· the species chiefly feed upon dead organic matter, fungi, etc , or form galls in a few cases

Only a few hundred members of the order have been described, and in most tropical lands thrips, as yet, have been very little studied, but the order is probably world-wide in its range. Australia contains numerous species including some of the largest forms, but no indigenous species have been found in New Zealand

BIBLIOGRAPHY—For the British species, *see* the papers by R Bagnall in *Journ Econ. Biology* (1911–13) and other journals; C B. Williams' account of the pea thrips in *Annals Applied Biology* (1915) is also valuable. For the North American species, *see* W. E Hinds, *Proc , U S Nat Museum* (vol xxvi, 1902) and for the structure of the mouth-parts, *see* A. Peterson, *Annals Entom Soc America* (vol. viii 1915) ; *see* also H. Priesner, *Thysanopteren Europas* (1926–28). (A. D. I)

THYSANURA, the name of an order of primitive wingless insects known as springtails and bristletails. They are recognizable by their elongate feelers and tail-processes (*cerci*). *Campodea* (*q v.*) *Machilis* and *Lepisma*—to which belongs the "silver-fish" (*q v.*)—are the best known genera. (*See* also APTERYGOTA)

THYSDRUS, an ancient city of North Africa (the site is occupied by the modern village of EL DJEM, 43 m S of Sousse by rail). It acquired importance owing to the fertility of its environs, and also as the meeting place of six ancient roads The amphitheatre, 163 by 133 yd., is the finest Roman monument in North Africa, and is second in size only to the Flavian amphitheatre (the Colosseum) in Rome.

THYSSAGETAE, an ancient tribe described by Herodotus (iv. 22, 123) as occupying a district to the north-east of Scythia separated from the Budini by a desert seven days' journey broad

THYSSEN, AUGUST (1842–1926), German industrialist, was born at Eschweiler on May 17, 1842, and, with his brother Josef, founded a firm in Duisburg for the manufacture of hoop iron, which became exceedingly prosperous during the Franco-Prussian war. After the war Thyssen established a factory at Mulheim, and then began the policy of grouping interdependent industries. In 1903 he began the formation of a metal "vertical" trust, which had interests in the iron-fields of Lorraine, in other raw materials of heavy industry, in shipping and in electrical power. The power of the group was consolidated in the World War of 1914–18 August Thyssen himself conducted the business personally until 1922. He died on April 15, 1926.

TIARA, the papal crown, a bee-hive shaped, somewhat bulging head-covering, ornamented with three crowns (whence *triregnum* or "triple crown"). It has no sacral character, being solely the ensign of sovereign power (*cf.* Innocent III. Serm. vii. *in S. Silvest*), and is therefore never worn at liturgical functions, when the pope always wears the mitre. The tiara is first mentioned, under the name of *camelaucum,* in the *Vita* of Pope Constantine (d 715), and next under the name of *pileus phrygius* or *phrygium,* or the *Constitutum Constantini,* the so-called "Donation of Constantine." In the 9th century it appears in the 9th *Ordo* of Mabillon in connection with the description of the consecration of the pope. On papal coins it first appears on those of Sergius III. (d. 911) and then on those of Benedict VII. (d. 983). At this period it was, according to the *Ordo* above mentioned, a sort of cap of white stuff, and helmet-shaped. Before the 9th century the tiara was certainly without any crown; any such ornament would not have been in keeping with the circumstances of the time, and seems also to be excluded by the terms of the *Constitutum Constantini.*

At the beginning of the 12th century, however, the papal tiara was already decorated with a circlet, as the 12th *Ordo* and statements made by Bruno of Segni (d. 1123) and Suger, abbot of St. Denys (1121–51), prove; but it is only in representations of the tiara dating from the late 13th century that the circlet appears as a regular spiked crown. The two pendants at the back of the tiara (*caudae, infulae*) are likewise only traceable to this period. The second circlet was added by Boniface VIII., as is proved by three statues executed during his lifetime (one in the Lateran church and two in the crypt of St. Peter's). The earliest effigy of a pope with a triple-crowned tiara is, therefore, that of Benedict XII. (d 1342), of which the head is preserved in the museum at Avignon, while an effigy of the same pope in the crypt of St. Peter's at Rome has a tiara with only two crowns.

TIARET (*Tahert*), a town of Algeria, in the Tell Atlas, department of Oran, 122 m S E of Mostaganem by rail. It occupies an important strategic position on a pass through the mountains at an elevation of 3,552 ft The Wadi Tiaret flows through the town in a series of cascades. The upper town, the residential quarter, is on the right bank of this stream. The citadel occupies a separate hill on the other side of the wadi. The chief business centre is the lower town where are also the principal public buildings. On another hill opposite the citadel is the native town. The railway, which ended there and which has been extended to Trumelet, forms the outlet of the fertile Sersou plateau, the 400,000 hectares of which have been completely transformed by colonization since 1900

The citadel occupies the site of a Roman station Tiaret (Berber for "station") was a town of note at the time of the Arab invasion of North Africa in the 7th century. In 761 it was taken by Abdurrahman ibn Rostem, the founder of the dynasty of the Beni Rustām (Rostem) Their empire, which during the reign of Abdurrahman (761–784) and his son Abdul Wahab (784–823) extended over the greater part of the modern Algeria, was known as the Ibadite Empire from Abdallah ibn Ibad, the founder of the heretical sect to which Abdurrahman belonged. The Ibadites represented the moderate section of the Kharijites (*See* Islam) Seven princes of the Rustamite house succeeded Abdul Wahab at Tiaret, but in 909 the dynasty was overthrown by the Fatimites The Ibadites, after being expelled from the Tell, took refuge in Wargla They were driven thence in the 11th century and migrated to Mzab, where their descendants still profess the Ibadite doctrines and traditions After its second capture by the Fatimites, Tiaret ceased to be the capital of a separate state For a long period it was included in the sultanate of Tlemçen, and in the 16th century fell to the Turks. It was one of the chief towns of Abd el Kader, but was occupied by the French in 1843 (*See* Algeria *Archaeology*.)

TIBER, a river of central Italy (anc. *Tiberis;* Ital. *Tevere*). It traverses the Tuscan Apennines—in which it rises at a point some 12 m N. of Pieve San Stefano, 4,160 ft. above sea-level, nearly 20 m east from the headwaters of the Arno—in a series of picturesque ravines, flows nearly south by Borgo S. Sepolcro and Città di Castello, then runs between Perugia and Todi to Orte, where it receives the Nera (which brings with it the waters of the Velino, *see* Terni), skirts the west foot of the Sabine Mountains in a broad shallow valley, then crosses the Roman Campagna, cutting its way through Rome, and finally enters the Tyrrhenian (Mediterranean) Sea by two arms at Ostia and Fiumicino, the latter artificial Its principal tributaries are the Paglia, the Nera and the Anio or Teverone, and it is generally navigable by boats up to the confluence of the Nera, a distance of 104 m., though, owing to the rapidity of the current, there is very little navigation above Rome. The total length of the river is 253 m., of which 21 m. lie between Rome and the sea. This latter portion of the river's course is tortuous, but in spite of this, and although the depth varies from only 7 to 20 ft., and in places at low water does not exceed 4 ft., it is nevertheless navigated by vessels up to 180 tons burden. The area of the Tiber basin is 6,719 sq m., and it is the largest in Italy except the Po The stream is heavily charged with sediment, and from that circumstance got its ancient epithet of *flavus* (tawny) The discharge at the mouth is 230 cubic metres per second, but it can fall as low as 90, and in floods rise to 3,400. It has advanced at each mouth about 2 m. since Roman times, while the effect of the sediment it brings down is seen on the north-west almost as far as Palo (anc *Alsium*), and on the south-east beyond Tor Paterno (*see* Laurentina Via) in the gradual advance of the coast The rate of advance at Fiumicino is estimated at 13 ft. per annum From Rome to the sea the fall is only 6 1,000. The arm which reaches the sea at Fiumicino is a canal, dug by Claudius and improved by Trajan (*see* Portus)

In the prehistoric period the mouth of the Tiber must have been situated at the point where the hills which follow it on each side cease, about 12 m. below Rome. On the right bank they are of Pliocene gravel, on the left of tufa; and on the latter, on a cliff above the river (the ancient *Puilia saxa*) stood Ficana (marked by the farmhouse of Dragoncello), which is said to have owed its origin to Ancus Martius. Beyond these hills the low coast belt formed by the solid matter brought down by the river begins; and on each side of the mouth in the flat ground were salt marshes. (*See* Ostia, Portus)

TIBERIAS, a town on the western shore of the Sea of Galilee, attractively situated on a narrow strip of land between the high ground and the water, 680 ft below sea-level (mod *Tabariyeh*); pop *c.* 7,000 The old city lay to the south of the modern Not much of archaeological interest remains visible, but excavations on the site of the old town are being conducted by the Jewish Exploration Fund.

History.—Tiberias was built about A D. 21 by Herod Antipas, and was so called after the emperor Tiberius Herod made it his capital and developed its life on Greek lines. The town was built on an ancient site, probably Rakkath (Josh. xix 35), and in the course of construction a graveyard was disturbed. In consequence the Jews, fearful of uncleanness, refused to live there, and Herod had to resort to compulsion to people his town (Joseph *Antiq.* xviii 2, 3). No mention is made of Tiberias in the gospels, except the casual reference in John vi 23. The city was of too recent date and too Hellenistic in outlook to invite attention; and it is unlikely that Christ ever visited it. It flung open its gates to Vespasian and his legions to earn consideration and favour. Hadrian sought to implant paganism by erecting a temple, but with no marked success. Towards the close of the 2nd century, the Sanhedrin transferred itself thither from its first Galilean home at Sepphoris From the rabbinic school at Tiberias came Judah hak-Kādhōsh, the collector and editor of the *Mishnah* (*c.* 220) The Talmud was there edited 200 years later The Jewish philosopher, Maimonides, and Rabbi 'Akiba are buried there.

Christianity found in Tiberias no congenial soil, and not until the 4th century could it make headway In the 5th century there was a bishop of Tiberias, who subscribed to the acts of the Council of Chalcedon In 637 came the Arabs When the crusaders established their kingdom of Jerusalem, Tancred was appointed ruler in Galilee, Tiberias became his capital and was in part rebuilt on a new site farther north In 1187, before the battle of Hattin, it fell into the hands of Saladin In the 18th century, Dhāhir el-Amir fortified the town; and in their advance on Damascus, British troops seized it in Oct. 1918. (E. Ro.)

TIBERIUS [Tiberius Claudius Nero] (42 B C.–A.D 37), Roman emperor, was born on Nov 16, 42 B C His father, who bore the same name, was an officer of Julius Caesar, who, after a stormy career, returned to Rome when the general amnesty was proclaimed in 39 B.C. Livia, the mother of Tiberius, was also of the Claudian family; her husband ceded her to Octavian in 38 shortly before Drusus, Tiberius's brother, was born. Livia had no children by Augustus, and therefore devoted all her remarkable gifts to the advancement of her sons. Tiberius passed through the list of state offices in the usual princely fashion, beginning with the quaestorship at the age of eighteen, and attaining the consulate for the first time at twenty-nine.

But from 22 to 6 B.C and again from A.D. 4 to 10 by far the greater part of Tiberius's time was spent in the camp. His first service was as legionary tribune in one of the desperate wars in the Spanish peninsula. In 20 B C. Augustus sent Tiberius with

an army to seat Tigranes of Armenia on the throne as a Roman vassal This he did without opposition He spent the following year as governor of Transalpine Gaul In the next year (15) he was despatched to aid his brother Drusus in subjugating the Raeti and Vindelici in the mountains at the source of the Rhine and Danube. Drusus attacked from the eastern side, while Tiberius operated from the upper waters of the Rhine, and the mountaineers were subdued, which ensured the safety of communications between northern Italy and Gaul. In 12 B C. Agrippa, the great general of Augustus, died at the age of fifty-one, leaving Julia, the emperor's only child, a widow. Agrippina, daughter of Agrippa by an earlier marriage, was wife of Tiberius, and had borne him a son, Drusus, afterwards father of Germanicus Livia, with great difficulty, prevailed upon Augustus to replace Agrippa by Tiberius, who was compelled to exchange Agrippina for Julia, to his bitter grief During the year of mourning for Agrippa, which delayed his new marriage, Tiberius was occupied with a victorious campaign against the Pannonians, followed by successful expeditions in the three succeeding summers For this he received the triumphal insignia, now first separated from the triumph itself Drusus died in 9 B C., and Tiberius became the first soldier of the empire

In the campaign of the year after Drusus's death Tiberius traversed all Germany between the Rhine and the Elbe, and met with slight opposition He was rewarded with the full triumph, the military title of "imperator," and his second consulship. In 7 B C there was another but insignificant campaign in Germany. Next year Augustus bestowed on his stepson the tribunician authority for five years.

Tiberius at this time suddenly begged permission to retire to Rhodes and devote himself to study He seems to have declined absolutely at the time to state his reasons for this course, but he obstinately adhered to it. The departure from Italy was as secret as it could be made. Years afterwards, when Tiberius broke silence about his motives, he declared that he had retired in order to allow the young princes, Gaius and Lucius, sons of Agrippa and Julia, a free course.

At Rhodes Tiberius lived simply, passing his time mainly in the company of Greek professors, with whom he associated on pretty equal terms After five years' absence from Rome, he begged for leave to return; but the boon was angrily refused, and Livia with difficulty got her son made nominally a legate of Augustus, so as in some degree to veil his disgrace The next two years were spent in solitude and gloom Then, on the intercession of Gaius, Augustus allowed Tiberius to come back to Rome, but on the express understanding that he was to hold aloof from public functions He had scarcely returned before death removed (A D. 2) Lucius, the younger of the two princes, and a year and a half later Gaius also died The emperor was thus left with only one male descendant, Agrippa Postumus, youngest son of Julia, and still a boy Four months after Gaius's death Augustus adopted Agrippa and at the same time Tiberius The emperor now indicated clearly his expectation that Tiberius would be his principal successor.

In A D 5 it became necessary to attack the formidable confederacy built up by Maroboduus, with its centre in Bohemia At the most critical moment, when Pannonia and Dalmatia broke out into insurrection, Maroboduus accepted an honourable peace. The four serious campaigns which the war cost displayed Tiberius at his best as a general. When he was about to celebrate his well-won triumphs, the terrible catastrophe to Varus and his legions (A D. 9) produced a profound change in the Roman policy towards Germany. Although Tiberius with his nephew and adopted son Germanicus made in A D 9 and 10 two more marches into the interior of Germany, the Rhine was permanently accepted as the frontier Tiberius was thus robbed in great part of the fruit of his campaigns; but nothing can deprive him of the credit of being a chief founder of the imperial system in the lands of Europe. From the beginning of 11, when he celebrated a magnificent triumph, to the time of the emperor's death in 14 Tiberius remained almost entirely in Italy, and held rather the position of joint emperor than that of expectant heir.

Tiberius ascended the throne at the age of fifty-six. What struck every one of his contemporaries most was his absolute impenetrability. Tiberius proved himself capable in every department of the state more by virtue of industry and application than by genius. His mind moved so slowly and he was accustomed to deliberate so long that men sometimes made the mistake of deeming him a waverer.

The change of masters had been anticipated by the Roman world with apprehension, but it was smoothly accomplished Livia expected to share the imperial authority with her son. At first Tiberius allowed some recognition to the claim; but he soon shook himself free, and later became estranged from his mother and held no communication with her for years before her death. The history of Tiberius's relations with other members of his family is hardly less miserable. Perhaps with any other commander than Germanicus the dangerous mutiny of the troops on the Rhine which broke out soon after Tiberius's accession would have ended in a march of the discontented legions upon the capital. The perilous episode of Arminius caused the recall of Germanicus and his despatch to the East on an honourable but comparatively inactive mission Tiberius seems to have set Piso to watch and thwart him, but there is no authority for the suspicion that he had him poisoned The death of Germanicus was followed four years later by that of the emperor's son Drusus When Drusus died, Tiberius nominated two of the sons of Agrippina, Germanicus' widow, as his heirs But Seianus, Tiberius's minister, had grown strong by nursing the emperor's suspicions and dislike for the household of Germanicus, and the mother and the princes were imprisoned on a charge of crime In his memoirs of his own life Tiberius declared that he killed Seianus because he had discovered that he entertained a mad rage against the sons of Germanicus But the destruction of Seianus did not save Agrippina and her two children. The third son, Gaius Caesar (Caligula), lived to become emperor when Tiberius died in 37

The care expended by Tiberius on the provinces was unremitting Soldiers, governors and officials of all kinds were kept in wholesome dread of vengeance if they oppressed their inferiors or encouraged irregularity of any kind Strict economy permitted light taxation and enabled the emperor to show generosity in periods of exceptional distress Public security both in Italy and abroad was maintained by a strong hand, and commerce was stimulated by the improvement of communications. Jurisdiction both within and without the capital was on the whole exercised with steadiness and equity, and the laws of the empire were at many points improved

Our ancient authorities are Tacitus, to some extent biased by senatorial traditions; Suetonius, a rather scandalous biographer; and Velleius Paterculus, the nearest in point of time, an officer who had served under him Dio is probably dependent on Tacitus The chief account of Tiberius in English is that contained in Dean Merivale's *History of the Romans under the Empire*. Professor E. S Beesly has written an interesting defence of him in his *Catiline, Clodius and Tiberius* (1878) The best recent history of this period is Hermann Schiller's *Geschichte der romischen Kaiserzeit* (Gotha, 1883) Much historical information is given in the editions of the *Annals* of Tacitus, of which the best in English is that of Furneaux (Oxford, 1884), Freytag, *Tiberius and Tacitus* (Berlin, 1870) (following Stahr, *Tiberius*, Berlin, 1863), exposes the inconsistencies of Tacitus' account. *See* also Ihne, *Zur Ehrenrettung des Kaisers Tiberius* (Strassburg, 1892), Gentile, *L'Imperatore Tiberio secondo la moderna critica storica* (1887); J C Tarver, *Tiberius the Tyrant* (1902); E S Beesly, *Cataline, Clodius and Tiberius* (1907); A Lang, *Kaiser Tiberius* (Jena, 1911); O Kuntz, *Tiberius Caesar and the Roman Constitution* (Seattle, 1924). For the imperial administration of the provinces by Tiberius *see* Mommsen, *History of Rome*, vol. v

TIBESTI, a mountainous region of the central Sahara, inhabited by the Tibbu (*q.v.*). Tibesti includes the highest summit of the Sahara, the volcanic massif of Kussi, which reaches 3,400 metres. The eruptive rocks have forced their way through a substratum of crystalline rocks covered by enormous thicknesses of horizontal Silurian grits, the scarp of which is quite brusque above the surrounding plains, which are some hundreds of metres above sea-level. Great dry water-courses, deeply cut in all the faces of the massif, indicate a climate formerly more humid. The daily variations of temperature reach 30° at times. The inhab-

itants, at most 10,000, are very poor. Tibesti had been partly explored by Nachtigall in 1870, since when no European went there till 1915, when Col Tilho wrote a very complete description of it, and mapped it. The frontier was fixed by the Franco-English convention of Sept. 8, 1919.

See S Tilho, *Exploration en Afrique centrale* (*La Géographie*, xxi, 1916–17); id *Carte de Tibesti* (*La Géographie*, xxxvi, 1921); C. Lofler, *La pacification du Tibesti* (*L'Afrique française*, 1916); D. A. A Rottier, *Étude sur le Tibesti* (*Bulletin du Comité d'études historiques et scientifiques de l'Afrique occidentale française*, 1922).

TIBET or **THIBET,** a country of Central Asia. It is the highest country in the world, comprising table-lands, averaging about 16,000ft. above the sea, the valleys being at 12,000 to 17,400ft, the peaks at 20,000 to 24,600ft, and the passes at 16,000 to 19,000 feet. It is bounded on the north by Sinkiang, on the north-east by Kuku-nor (Koko-nor, *q v*), on the east by Chwanben (or Chamben or Chwampien or Kham), on the west by Kashmir and Ladakh, and on the south by India, Nepal and Bhutan. The indefinite position of Chwanben (Chwampien) and Kuku-nor, and the doubtful limits between Tibet and Sinkiang prevent any calculation of the area of Tibet; its population is probably less than 3,000,000.

Origin of Name.—The Tibetans call their country Bod, which word in colloquial pronunciation is aspirated into *Bhod* or *Bhot*, and in the modern Lhasa dialect is curtailed into *Bho* Hence the country is known to Indians as *Bhōt*, and the inhabitants as *Bhōt-ias*. This territory came to be known to Europeans as "Tibet," evidently because the great plateau, with its uplands bordering the frontiers of China, Mongolia and Kashmir, through which travellers communicated with this country, is called by the natives *Tò-bhot* (written *stod-bod*) or "High *Bod*" or "Tibet"

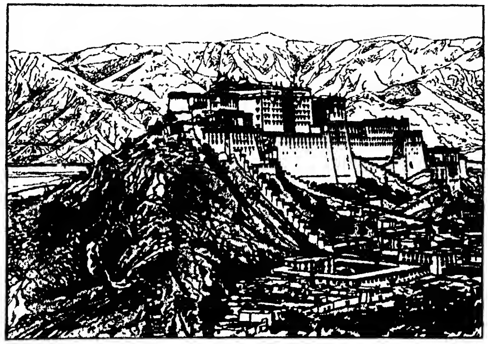
Physical Geography.—Almost all the country from the south of the Takla-makan desert to the Himalaya was formerly included under the name of Tibet in general usage The Kuenlun mts were, under this scheme, the northern mountains of Tibet, they are in any case the oldest of the great mountain-systems of the Tibetan highland. Their rocks are mostly Lower Palaeozoic and highly metamorphosed, while Mesozoic deposits occur only as land sediments in the valleys of the chain; this part and the region to the north and north-east have thus apparently been land since Triassic times To the south of the Kuenlun Mesozoic deposits become more important, and suggest that the broad zone between that chain and the Deccan (part of the ancient Gondwanaland) was then largely under water at times, though during the Upper Jurassic phase land conditions prevailed over wide areas In the Cretaceous epoch began the great upfolding of the Himalayan region, which probably reached its maximum activity in the Eocene age. Parts of this folding seem to have been directed southward, as is indicated in the Garwhal thrust-plane, but the story is highly complex and there is much penetration of young volcanic rocks, while geysers and hot springs tell the same tale. In the uprise of the younger mountains not only did great fault-lines appear in the south and east of the Tibetan highland, but also the Kuenlun was much broken, and the old Tarim block to the north of it sank In several parts of its area the Kuenlun attains a height of 7,000 metres, while, in the west, the peak Mustagh (Muztagh or K5) attains 7,282 metres (23,890 ft), and is, perhaps, the highest point in the chain, though it has been claimed that there are within it heights of nearly 8,000 metres.

Between the western Kuenlun and the Himalaya is the great dissected highland of the Karakorum The heights attained in the Karakorum are very great, several summits attaining about 8,000 metres, while K2 is 8,610 metres or 28,248 ft. high

On the general Tibetan highland the oldest formation exposed is the Upper Jurassic, betraying land conditions followed in the next phase by submersion. The highland seems to pass into the mountain-systems of its periphery and to have a general height of 15,000–16,000ft.; the highest point known in this region is about 23,600 feet. There are many fault-lines, thrust lines and hot springs. This plateau of inland drainage, characterized by lakes, mostly salt, and hot springs, is called Chang-t'ang.

The southern rim of the general highland just described is the trans-Himalaya or Hedin range of mountains, the average height of which may exceed that of the Himalaya, though the highest peaks (nearly 24,000ft) are not so great as those of either the Himalaya or the Karakorum This great series of mountains was very little known until Sven Hed'n explored there

South of the trans-Himalaya lie the deep valley lines of the Indus, Sutlej and Brahmaputra, so this range forms the watershed between an area of internal drainage to the north and a region of the sources of great rivers to the south; it is noteworthy that the three great rivers mentioned make their way through the Himalaya to the south, and many feeders of the Brahmaputra, Ganges and Indus have also penetrated into the Himalaya Between Bunji, in Gilgit, and the Darel district the bed of the Indus is about 915 metres above sea-level, while the crests on either side of the gorge rise to 6 000 metres, or 20,000 feet. The Brahmaputra way through is as striking, for the river reaches down to the 10,000ft. contour only as it begins to work around the base of Nameha Batwa, 25,445ft high



LHASA, SHOWING THE POTALA, THE EARLY 17TH CENTURY FORTRESS PALACE OF THE DALAI LAMA, AND THE CITY BELOW

The long line of the Upper Indus and Upper Brahmaputra is the most marked feature of southern Tibet, and the Upper Sutlej follows a closely related line between them Some tributaries of the Brahmaputra join the main river in such a way as to suggest that it once flowed westwards, and that its present course is a result of capture Near the source of the Sutlej are the two sacred lakes, Manasarowar and Rakas-tal, which communicate by a channel of water after heavy rain.

The snow line is usually, but not quite always, higher on the north than in the south, because of the much heavier precipitation on the south; on this latter side it is said to run near the 5,000 metre (16,400ft) contour Near Leh it is at 5,300–5,800 metres, and in the Karakorum at 5,600–5,900 metres The glaciers formerly reached down to 3,300–3 600 metres in the Spiti region and to 2,100 metres in the Upper Indus region It is thus highly probable that during the maximal ice phases the whole of the great highland was glaciated, with no doubt some lines of crest projecting above the ice-sheets The Pleistocene deposits are enormously thick in many places, an estimate of 3,000ft. having been made for this in the upper Sutlej valley

A remarkable economic feature is the almost universal distribution of gold through Tibet. The gold-digging is referred to in somewhat mythical terms by Herodotus Every river which rises in Tibet washes down sands impregnated with gold, and it has been proved that this gold is not the product of intervening strata, but must have existed primarily in crystalline rocks of the main axes of upheaval In western Tibet the gold mines of Jalung have been worked since 1875

Iron is found in eastern Tibet in the form of pyrites, and is rudely smelted locally. Salt, soda, potash and borax exist in abundance in the western lake regions (Chang-t'ang).

Climate.—Tibet lies so high that its climatic relations are very peculiar. The Himalaya captures most of the rainfall of the summer monsoon, but a little gets through the passes and is captured by the trans-Himalaya, beyond which the climate is

extremely dry and we are in the region of internal drainage.

In July the Tarim basin has average temperatures varying from 68° to as high as 90° F. in different places. On the Tibetan highland figures are lower and are correlated with elevation; thus, at an elevation of 3,000 metres the temperature in July in north Tibet is known for one or two stations and is about 59°, for a station at 4,000 metres it is less than 50°, and for the general area of Chang-t'ang, with a height of 5,000 metres, it is probably about 40°, or even less But the daily variations are extreme.

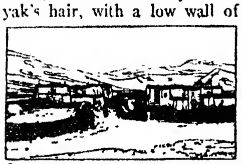
There is more snow in the winter, towards the west, and more rain, in the summer, towards the south-east The total fall of rain and snow over most of Tibet, except the south-east and patches of the trans-Himalaya, is about 8in per annum.

Vegetation.—The severe conditions of Chang-t'ang limit its plants to some high-steppe grasses in the valleys, with a few bushes here and there up to the 15,000ft. contour. Towards the western Kuenlun, on the one hand, and towards the Chinese border on the other, there is more woodland Prjevalsky, the pioneer collector, and Thistleton-Dyer class the flora as Arctic-Alpine and ancient, with many endemic species. It is chiefly composed of immigrants from the Himalaya and Mongolia. The river valleys between the Himalaya and trans-Himalaya, are warmer, and peaches, apricots, apples, plums, grapes, water-melons, and even pomegranates are raised, while trees include plane, poplar, maple, walnut, oak, cypress and a variety of conifers. Barley and buckwheat are the chief cereals.

Animals.—Herds of yak, wild ass (kiang) musk deer, Tibetan antelope (*Pantholops*), wild sheep (*bharal* of the Himalayas) and wild goats roam the high wastes, while bears, leopards, wolves, foxes, marmots, squirrels, monkeys, cats and dogs also occur. The sloth-bear (*Aeluropus*) and the so-called unicorn-antelope (*Budorcas*) are Indo-Malayan forms that reach up into Tibet. Several water-fowl breed in Tibet, notably the bar-headed goose (*Anser indicus*) and towards the eastern borders there occur several rare and handsome varieties of pheasant

Population and Economic Life.—The people of Tibet, like its plants, must be considered as post-glacial immigrants, Tibet having apparently been an ice desert during the phases of great extension of the ice-sheets. Indeed, it is doubtful whether mankind could spread up into these wastes until long after the last ice-maximum had passed away This helps to interpret the further fact that the majority of the inhabitants is related in physical type to the peoples of the steppes and deserts farther to the north The Tibetans have high power of resistance to cold and hunger if they can obtain buttered tea, which they drink at frequent intervals. The country can support only a small population, and estimates are mostly below 3,000,000, a large number of these being celibates in monasteries. (*See* LAMAISM) Polyandry is practised to a certain extent, the brothers in a family, in such a case, having a wife in common

The herdsmen, tent-dwellers, among them are usually called Drok-pa, and their tents are of yak's hair, with a low wall of dung or stones around the tent-base. The tents are moved at intervals. and once a year the herdsmen make their way down-hill to market, mostly at Lhasa. Their food is mainly composed of products of yak's milk The peasant-cultivator inhabits chiefly the valleys of the south and south-east, and is mostly tied to the soil, partly, no doubt, because men are so scarce The crop rotation may give the sequence. barley, fallow, barley, peas, wheat, and the plough is drawn by oxen or yaks.



A TIBETAN VILLAGE ON THE PLAIN OF THE THREE BROTHERS, 14,700 FT. ABOVE SEA-LEVEL

In addition to herding and agriculture a certain amount of wool-spinning, weaving and knitting is fairly widely-distributed in Tibet, but the immense importance of religious matters in this country makes the production of images and cult-objects a more important matter.

Tibet is so difficult a country that the steppe-conquerors of various periods have usually avoided it completely, and it has practical autonomy, in spite of varying relations, chiefly diplomatic, with China, and to some extent with Britain, through India, and even at times with Russia. Its central position and the longitudinal valleys of the Brahmaputra (Sanpo), the Sutlej and the Indus—the passes from the last across into the Tarim basin—and the communications via the valleys of the two last and other Himalayan streams with Kashmir and India, have made Tibet of importance in the caravan trade across Asia.

Batung (Ba'an-fu) and Chamdo in Kham (Chwanben) are among the stations on the ways up from China, the former connecting more especially with Szechuan and Yunnan, the latter with Szechuan, Kansu and Mongolia. To the west, in Tibet proper, the valley between the Himalaya and the trans-Himalaya provides the main line of communication, and portions of the Brahmaputra are navigable. Lhasa is the chief station. From Lhasa it is possible to go south, via Gyantse, to the passes between high peaks that lead to Sikkim and India. Ya-tung in the Chumbi valley, was created a mart for Indo-Tibetan trade by the regulations appended (1893) to the Sikkim-Tibet convention of 1890, but it was not successful, and in 1904 an additional mart was fixed at Gyantse Westward from Lhasa the trade route goes to Shigatse and on past the sacred lakes, Manasarowar and Rakas-tal, reaching the Indus system near Gartok, another mart for Indo-Tibetan trade fixed by the 1904 convention. Gartok has ways leading through the Himalaya south to Almora, and a less important one west to Simla; it stands more than 14,000ft above sea-level. From Gartok the trade route goes on down the Indus to the mart at Leh, the capital of Ladakh, whence there are routes to Kashmir and to the Tarim basin The main route through Tibet here described is known as the Janglam. The high wilderness of the Chang-t'ang is of less importance for transit purposes, but a route from Lhasa goes north via Nag-chu-ka, farther east, to Urga, in Mongolia. Camels are left at Nag-chu-ka on the way to Lhasa, and the caravans assemble twice a year at Kuku-nor (lake), reaching Lhasa in August and in January. Mules are much used, as also are yaks Musk, wool and woollen materials, furs, rhubarb, yak's tails, cult-objects, medicinal herbs, etc., are carried especially to China, and tea, rice, porcelain, horses, cereals, silks are imported thence. The trade with India is mainly an exchange of Tibetan wool for manufactured goods Postal transport may, with good fortune, cover as much as 75m. a day, and there is a telegraph line from Lhasa to Gyantse

Government.—The ruler is the Dalai Lama, who lives in a palace near Lhasa and is nominally supreme both in civil and in religious affairs. He is supposed to be chosen by the heads of the three chief Buddhist monasteries of Lhasa (Ganden, Sera and Drepung) with the help of the State oracle at Lhasa and the oracle at Sam-ye. The second lama of the Tibetan Church is the head of the monastery of Tashi-lhunpo, near Shigatse, and this Dalai Lama is held by some Tibetans to have a spiritual authority higher than that of the Dalai Lama The renown of Tashi-lhünpo is chiefly a matter of the last three centuries, and at various times it has sought to undermine the power of the Dalai Lama, who keeps agents to watch matters at Shigatse. Until 1912, the amban, or representative of China, had a share in government and in the selection of a Dalai Lama, but in that year the amban, whose power had long been waning, was expelled. The Dalai Lama has a chief secretary who may have great power; he is supposed to act with a greater and a lesser council and a national assembly, and these bodies have an official who may be called a prime minister, but the Dalai Lama and his secretary have been known to set aside the authority of prime minister and council. A lord chamberlain is the head of the country's ecclesiastical officials, under the Dalai Lama. There is naturally a good deal of local autonomy in outlying areas of a region with such difficulties of communication, but the personal authority and prestige of the Dalai Lama have often been very marked. It arises partly from the fact that the occupiers of this great position have on several occasions proved themselves to be strong-minded men, and partly from the fact that the supreme head is held to be one who has won the right to Nirvana but has consented to rebirth for the sake of his fellow men. As such he is venerated, not only in

Tibet, but, in varying degrees wherever, in Asia, Buddhist ideas have penetrated and maintained themselves.

ETHNOLOGY

I. GENERAL

The Mongolian plateau is the origin of a considerable part of the population, in which other elements have been discovered, including a type with fairly long heads, wavy, even curly hair, as well as lightish hair

The people may be roughly divided into four main classes, namely, the nobility, the traders, the peasants, and the herdsmen Many of the nobility reside in Lhasa They have also their country residences scattered over the country. Next in the social scale come the traders These are usually laymen, though many also among the monks trade on behalf of their monasteries The traders move about into all parts of the country, spending perhaps a portion of the year in the north to obtain salt from the lakes, in the east, trading in tea with China, and in the south selling wool, yak-tails, hides, etc, in India, and bringing thence cotton goods and the varied utilities of western civilization.

There is no strong middle-class in Tibet The peasant farms generally on a small scale He works in the fields of the local nobleman, monastery or other landlord, as well as tending his own small plot of land The herdsmen seek pastures for their flocks mainly in the uplands, at altitudes of over 14,000ft, and frequently move their camps to new ground Among other members of the social organization are the beggars and the brigands.

BY COURTESY OF THE UNITED CHRISTIAN MISSIONARY SOCIETY

A TIBETAN NOMAD CHIEF CARRYING A CHARM BOX UNDER HIS LEFT ARM

Bodily Traits.—The males are short, often not more than 5ft. 5in. in height, except in eastern Tibet, where 5ft 9in is a general height; the females are appreciably shorter. The head is mesaticephalic, verging on brachycephalic in the case of many of the hereditary herdsmen, the hair is black and somewhat wavy; the eyes are usually of a clear brown, in some cases even hazel; the cheek-bones are high, the nose is thick, sometimes depressed at the root, in other cases prominent, even aquiline, though the nostrils are broad The teeth are strong but irregular; the ears, with tolerably large lobes, stand out from the head The mouth is broad, the lips not full, and, among the people of the lower altitudes, decidedly thin. The beard is sparse, and is often plucked out with tweezers. Moustaches are worn occasionally.

The shoulders are broad, the arms round. The legs are moderately developed in the people of the central and more settled parts of the country. But the eastern Tibetans and the Bhutanese branch of the Tibetan race, being all hardy denizens of steep and lofty mountains, have not only well-developed legs but are in general physical build fine specimens of the human race. The foot is somewhat small but broad, the hand coarse The waist is much less pronounced than among many nations, as is quickly recognized by Europeans and Americans who don Tibetan attire The colour of the skin is a light brown, sometimes so light as to show ruddy cheeks in children, though where exposed to the weather it becomes dark brown.

Dwellings.—The landed proprietors live in houses, solidly built around a rectangular courtyard. On three sides of this courtyard are stables and storehouses; on the fourth, opposite the gate, is the mansion itself, one or two storeys higher than the other three sides, and sometimes as much as five storeys in height. The walls are constructed of flat stones bound together with mud In the smaller buildings, and especially in the upper layers, the stones are replaced by sun-dried bricks The roof is flat, and is formed like the earth floor, but is not polished Windows are plentiful, but glass is rare Its place is taken by waxcloth or other similar material, strong wooden shutters protecting this from rough usage The houses of the peasants are, as a rule, solid and substantial Here, too, the walls are of stone or sun-dried bricks, though occasionally of clods of earth Flat roofs of beaten earth are the rule throughout the interior of the country, but in the Chumbi valley and other rainy districts they are laid on a gentle slope Where pine trees grow, the roofs are constructed of pine shingles, kept in position by heavy stones The shepherds and herdsmen dwell in tents of yak-hair These tents are rectangular in shape, often some 12ft in length, but sometimes up to 50 feet. An aperture, about two feet in width along the middle of the roof, lets out the smoke

Food and Drink.—The staple diet of the ordinary Tibetan is yak's meat, mutton, barley flour, cheese and tea The rich, and those who dwell in the lower altitudes, also eat fruit and vegetables in small quantities The climate is so cold that Tibetans are compelled to eat meat, although as Buddhists they should abstain from doing so, and the production of grain, vegetables or fruit at great altitudes is very difficult Rice cannot be grown in the cold uplands, and is thus a luxury for the wealthy only The chief Tibetan grain food is barley

The main beverage is tea Brick tea from China is used, and is boiled up in water flavoured with soda When thoroughly boiled, the mixture is taken out with a ladle and poured through a strainer into a churn Butter and salt are added and the whole churned until it is well mixed. It looks then like *café au lait*. The consumption of this beverage among Tibetans is enormous, for they drink on an average from 30 to 50 cups of tea a day They eschew tea as known in Europe and America, finding it indigestible and lacking in nutriment The other chief beverage is beer It is brewed from barley, and being but mildly intoxicating, a good deal can be drunk with impunity

Religion.—Religion occupies a predominant position in the life of the Tibetan people Their religion is the form of Buddhism (*see* Mahayana and Lamaism), which was introduced into Tibet in the 7th century A D under King Song-tsen Gam-po. It includes a widespread belief in reincarnation An incarnation may be born into any family, however humble; for example, the Dalai Lama, the religious and secular ruler of the whole country, has often reincarnated in the family of a peasant Hermits are found here and there throughout the land, in houses, in caves, in cliff-side dwellings. Oracles are in daily use, furnishing prophecies for the State and for the village, as well as for individuals.

Pilgrims are ubiquitous A traveller in Tibet or on the borderland is sure to meet them on their way to holy temples, to snow mountains inhabited by spirits, to the foot-prints of departed saints stamped on the rocks, and other sacred objects. Some will cover every yard of the way with their prostrate bodies. Lying on his face, the pilgrim makes a mark with his fingers a little beyond his head. Rising, he brings his feet to this point, and again, muttering a prayer, prostrates himself. Such a pilgrimage may well take two or three years. It would, perhaps, be safe to say that, judging by the amount of their time and their money which they devote to religion, the Tibetans are one of the most —if not the most—religious people in the world. A huge number, estimated by some at a seventh, by others as high as a

fourth, of the entire male population, enters the priesthood. Great monasteries, often housing more than a thousand monks, are scattered over the countryside, as well as hermitages and smaller collections of priests.

The priesthood is divided into two main divisions. There is the original establishment known as *Nying-ma*, dating from the 7th century of the Christian era, when Buddhism first made real headway in Tibet. And there is the reformed sect, known as *Ge-luk*, which dates from the 14th century of the same era The *Nying-ma* is divided into a number of sects, among whom the *Ka-gyü* have numerous adherents, especially in Bhutan The different sects abstain from open dispute with each other, so that the religion is not torn by sectarian disputes, but presents a united front to the outside world

A TIBETAN WOMAN WEARING NATIVE HEAD-DRESS AND CHARM BOX ON THE THROAT

National Characteristics.—The Tibetans are a cheerful, pleasure-loving people. Their chief forms of recreation include gambling, horse-racing, picnics (held especially in the parks which surround such few large towns as there are) and theatrical entertainments. They are particularly fond of the last, which often form part of their religious festivals. Another very marked characteristic is their insistence on ceremonial and etiquette. The form of address used towards a social superior, equal or inferior, the presentation of ceremonial scarves, and many other details of daily intercourse rest on rules which are observed by high and low.

II. DETAILS OF SOCIAL ORGANIZATION

The Nobles.—The nobility are a class apart. The Tibetan nobleman traces his descent to one of three sources It may be that an ancestor was ennobled for good work done for the country. The founder of the Pa-lha family, for example, was a Bhutanese ex-priest of the 17th century, whose work in the service of the Lhasa Government was rewarded by a place on the supreme council and the gift of an estate near Gyantse containing 130 farms. Secondly, the family in which a Dalai Lama or a Tashi Lama takes re-birth, however lowly it may be, is *ipso facto* ennobled and receives large estates from the Government. Some of the leading Lhasa nobles are descended from the brothers of previous Dalai Lamas. The third section of the aristocracy is the oldest and smallest of all. They trace their ancestry right back to the early monarchs who ruled Tibet before the 10th century of the Christian era. The houses of Lha-gyal-ri and Ra-ka-shar both claim unbroken descent from these early rulers, who are known as the "Religious Kings." Thus the heads of these two families are even now greeted by their tenants with the forms of obeisance that are accorded only to Lamas.

The nobility of Tibet are wealthy by comparison with their fellow-subjects. For instance, on the Pa-lha estates there are at least 1,400 farms, as well as 13 grazing grounds, each of the latter supporting 15 to 20 families of graziers. The tenantry pay rent in service, grain and cash. Out of this the nobleman pays a considerable proportion to the Government, both in cash and in grain He also passes on to the Government some of the service of his peasants, to provide transport animals, etc., for travellers armed with a governmental authorization for the same. In addition to taxes, the nobleman's family is bound to supply one or two members to work as Government officials at nominal salaries.

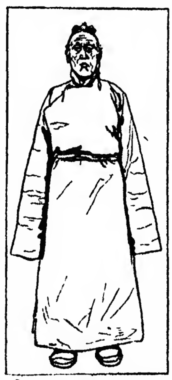
The laws of inheritance vary in different parts of the country. In central Tibet, when the father dies the sons usually remain in joint possession. When there are sons, daughters receive no portion of the land, but are given a small share when they marry. If, however, a nobleman dies leaving a daughter but no son, this daughter inherits the property. When she marries she adopts her husband into her family. She does not take his name; he takes hers. She is entitled to the deciding voice in the management of the property. There have been innumerable instances of such adoption among the high families of Lhasa. As a general rule the daughter succeeds in preference to a nephew. Throughout the greater part of Tibet there are families of noble stock. In the Tsang provinces are eight or nine who stand above the others. Eastern Tibet has its chiefs, styled *Gyal-po, De-ba*, etc. Ladakh has a remnant of the royal line, and Sikkim, till recently part of Tibet, has its ruler descended from an eastern Tibetan chief.

The names of the leading Lhasa families are as follows:—*Chang-lo-chen, Do-ring, Hor-kang, Lha-ding, Lha-lu, Nam-se-ling, Pa-lha, Pün-kang, Ra-ka-shar, Ram-pa, Sam-trup Po-trang, Se-chung, Sha-tra, Sur-kang, Tom-pa, Trum-pa, Yap-shi Sar-pa,* (*i.e.*, "The New Patrimony"), the name by which the family of an existing Dalai Lama is known. When the latter dies, his family take another name. The family of *Lha-gyal-ri* does not belong to Lhasa.

The Traders.—Tibetan society falls almost entirely into two classes, the landed gentry on the one side, and the peasantry and shepherds on the other. Such middle-class as there is, however, is provided by the traders. The chief articles of export are wool, yak-tails, hides, the soft underwool of the shawl-wool goat, borax, salt, musk and medicinal herbs. The chief imports are tea and cotton goods; and, in a smaller degree, woollen goods, hardware, corals, precious stones, tobacco, dried fruits, sugar, molasses and matches, needles, soap, etc. (*See* also INDUSTRY) The trading instinct is deeply embedded in the Tibetan character. Nobles and monks alike engage in trade, as well as the ordinary class of professional traders. The large monasteries trade widely, and are able to do so because each has its administrative department. Even the robber tribes issue from their haunts and go to other districts to trade.

Women often manage the shops and the general retail trade Especially is this the case in Lhasa; men take charge of the commercial dealings which necessitate long journeys, and in any case in which the issue is a large one the decision as a rule rests with them The wealthiest traders may be seen together with the poorest, exposing their goods for sale in the market-places

The Peasants.—On plains and in valleys that lie below an elevation of 14,000ft above sea-level there is much land that is fit for the plough But, owing to the steadily decreasing population, largely a result of the overwhelming proportion of celibate monks, the problem of obtaining sufficient man-power to carry on the every-day duties of life is a very real one; and in no department is it more acute than in that of the cultivation of the soil. Tibet does not lack land for cultivation, but she lacks the men to till it. This is emphasized by the fact that a peasant is not allowed to quit his home without first obtaining the landlord's permission. If he wishes to go away, he must ask for leave, or, as the Tibetan phrase runs, "petition for man-separation." He must also pay a large sum if the request is allowed, but such permission is usually refused.



A TIBETAN NOBLEMAN Showing characteristic costume and official ear-ring

There is a great gulf fixed between the peasant and his landlord. The former must use a different vocabulary when addressing the latter and bow low before him But there is mutual fellowship between the two, and the tenantry usually take a pride in the standing and traditions of the master, whom they surround and serve. The larger landed proprietors have, after feudal fashion, large staffs of servants, of whom many are employed during the winter, when the land is icebound, in spinning wool and weaving it into cloth. This is utilized in part for the servants' clothes; the balance is sold to traders or to neighbours.

Slavery is not common in Tibet, and where it occurs the slaves are often treated better than the paid servants or tenants. They are allowed to move about freely, and, when not at work, they

TIBETAN VIEWS

1. A Tibetan sheep herder's camp in the high hills of western Tibet. Tents are made of heavy woven rugs on account of the cold nights. 2. Pack caravan resting on one of the perilous trails crossing the Himalayan mountains. Sheep are largely used for pack animals on account of their sure-footedness. 3. A Yellow-Hat Lama reading scriptures to a group of followers. The Yellow Hat order was founded by Tsong Kha-pa in the 14th century. Members are forbidden to marry or drink wine. They have a very strict code of morals. 4. The Dalai Lama, religious and secular ruler of Tibet; religious head of Mongols and of many Buddhists in China and Russia. 5. Tashi Lama of the monastery of Tashilhunpo near Shigatse, inferior to the Dalai Lama in secular authority. 6. Lama dance. The performance is built around Buddhist symbolism and enacted for the purpose of glorifying Tibetan Buddhism. Dancers are elaborately costumed. 7. Meal time in Tibet. Tea is made in iron pot then put in churn-like container, where butter and spices are added. Some of the Tibetans mix barley flour with it, making both food and drink

have only to attend a roll-call in the morning and in the evening. The theatrical troupes that tour Tibet are mainly recruited from the peasants. When their tour is finished the actors return to their crops and their cattle.

Dress.—The dress of both sexes and of all classes in Tibet may conveniently be described here. It consists of a very full gown with a high collar and long sleeves. In the summer this is usually of the ordinary Tibetan cloth among the peasantry, and of silk among the wealthier classes. The winter gown is sometimes of sheepskin, sometimes of cloth lined with lambskin or wadded cotton. Tied tightly round the waist with a woollen or cotton band, it is puffed out above, and in the capacious pocket thus formed are carried drinking cups and other odds and ends. For laymen the robe reaches to the knee, for priests and women to the ankle. In central Tibet, and in parts of eastern Tibet, the women wear aprons, woven in varied colours, and often so broad that they nearly meet at the back. Shirts are of cotton or silk; trousers differ greatly in shape from the European pattern, and are of silk or cloth. The boot is of cloth, felt or leather, and of various colours. It rises to the knee, with a slit behind the knee, and is tied with gay-coloured woollen garters 3ft. or 4ft. long.

BY COURTESY OF THE UNITED CHRISTIAN MISSIONARY SOCIETY

A TIBETAN WOMAN IN EVERYDAY COSTUME

Men's hats are of various kinds, but are usually fur-trimmed in winter. The women of Tibet, especially those who rank among the upper classes, make no small display of dress and ornaments. The chief ornament is the head-dress; those of the upper classes are bedecked with pearls, turquoises and corals on a wooden frame Men, and particularly shepherds and herdsmen, adorn their hair with rings of silver and ivory. It is only in a few districts that men wear necklaces Ear-rings are very common, and among the official classes universal The official ear-ring is of a standard pattern. Long and narrow, it hangs from a gold ring with a pearl in the middle attached to the left ear. For the rest it is a string of turquoises, except that an inflexible rule requires the elongated lower end to be not a true turquoise, but an imitation. In the right ear a rough turquoise is worn, and this by all classes, official and unofficial, rich and poor.

Shepherds and Herdsmen.—The shepherd and grazier class are hardy and independent. Those in the uplands (and many shepherds live at high altitudes) descend to lower levels once a year to sell their products and buy barley, wheat, tea, turnips and woollen cloth, such necessities as cannot be obtained away from cultivated regions The shepherd, like the cultivator, is frequently in the employ of, or under contract to, one of the nobility or landed gentry. The Pa-lha household, for instance, owns some 20,000 sheep altogether, which are grazed in scattered grazing grounds within 50m. of Gyantse.

The butter of sheep and goats is consumed by poor people only. The gentry and the richer people generally eat only the butter from the *dri,* or female yak, and the cross-breeds between the yak and the ordinary cattle. The women take their share of the work. In addition to the milking and buttermaking, they grind the barley and perform the varied duties round the tents. The children help them in this, some going out with the sheep and goats, but not much with the yaks till they are 12 or 13 years old.

The Women.—The position of women in Tibet deserves special mention. Compared with those of other eastern races, they hold, and have always held, a remarkably high status. In olden days when the country was split up into a number of principalities, each ruled by its own chief, the ruler was occasionally a woman. Even in modern days, chiefs, ministers and officials of all grades consult their wives in their official work. In religious doings, however, the position of women is lower. For instance, of the three forms of blessing accorded by the Dalai Lama to different suppliants (touching the head with both his hands, with one hand, and merely with a tassel) the last and lowest form is the one used for all women, excepting only one. This solitary exception is Dor-je Pa-mo, the sole female incarnation in Tibet. She is one of the highest of all the incarnations, and is the head of a monastary (not a nunnery) at Sam-ding on the Yam-dro lake.

Tibetan women are physically strong. They perform heavy manual tasks. When not tanned by exposure to the elements, they are often fair, and those of the upper classes take great care of their complexions. Throughout Tibet it is a general custom for women to smear caoutchouc on their faces. Rough pads of felt which have been soaked in a red colouring matter are used. In addition to the head-dress, which has been described above, numerous ornaments are worn, rings, ear-rings, necklaces and girdles. The women lay charm boxes on the chest immediately below the throat. These usually contain a small image of a deity and a talisman specially written for the wearer by a Lama

Marriage.—Although the Tibetan woman enjoys a great measure of independence, she usually has little or no share in the choice of her husband A son is consulted by his father as to the bride proposed for him, but the parents consult a daughter hardly at all. The preliminaries attaching to a wedding, and the wedding ceremony, vary somewhat according to the district and the rank of the bride and bridegroom. The horoscopes of the pair must agree, and an auspicious day be fixed for the exchange of presents to take place as well as for the actual ceremony. The ceremony itself is attended by prayers, blessings, the exchange of ceremonial scarves, and feasting The priests of the unreformed, *i e.,* Red Hat, sect are permitted to marry. A Lama's wife, however, is not known by the same designation as the wife of a layman, but as "proprietress." Thus is the idea conveyed that the Lama and his belongings are in her charge, so that he is free to devote himself to religion.

Monogamy, polygamy and polyandry are all common in Tibet, especially the first Polygamy is practised among those whose wealth suffices to support more than one wife. Polyandry is found among the herdsmen and the farmers. Where it holds, the husbands are brothers Having married one of the brothers in a family the wife marries also all the other brothers who are younger, but not any that are older than he

HISTORY

Legendary.—Prior to the seventh century of the Christian era, Tibetan history is wrapt in myth and legend, helped out from time to time by sidelights from contemporary Chinese history According to native tradition the Tibetan race was descended from a monkey into whose body had entered the Compassionate Spirit, known as *Chen-re-si* in Tibet and *Avalokitesvara* in India. This spirit, with a she-devil, produced the first Tibetan offspring.

The early legendary kings of this country commence with Nya-tri Tsen-po, said to have been the fifth son of the Indian King Prasenajit of Kosala. He fled north of the Himalaya into Tibet, where he was elected king by the twelve chiefs of the tribes of southern and central Tibet. He took up his residence in the Yar-lung country south of Lhasa The first king and his six successors are known as the seven celestial *ti;* the next series consists of six kings known as the earthly *lek;* and they are followed by eight terrestrial *dé.* This threefold succession is apparently an imitation of the ancient legend of heavenly, earthly and human rulers, which was carried into Persia and China, and from the latter country into Japan and Tibet. The kings were followed by four rulers simply called *tsen, i.e.,* "mighty."

The king next in order was Lha-to To-ri Nyan-tsen. It was during his reign that the first Buddhist objects are reputed to have reached Tibet, probably from Nepal. They are said to have fallen from heaven into his palace during his eightieth year. The fourth of his successors was Nam-ri Song-tsen, who died in 630. During his reign the Tibetans obtained their first knowledge of arithmetic and medicine from China; the prosperity and pastoral wealth of

the country were so great that "the king built his palace with cement moistened with the milk of the cow and the yak"

The Early Kings.—With his illustrious son Song-tsen Gam-po the real Tibetan history commences He came to the throne when but thirteen years old, and reigned for many years He pushed forward the Buddhist influence in Tibet, and introduced an alphabet, basing it mainly on the Indian alphabet then used in Kashmir.

As a conqueror he extended his sway from the still unsubdued Kiang tribes of the north to Ladak in the west, and in the south he carried his power through Nepal to the Indian side of the Himalaya. How far southward this dominion at first extended is not known; but in 703 Nepal and the country of the Brahmans rebelled, and the Tibetan king, the third successor of Song-tsen Gam-po, was killed while attempting to restore his power It is noteworthy that nothing is said of this Tibetan rule in India, except in the Chinese annals, where it is mentioned until the end of the monarchy in the 10th century, as extending over Bengal to the sea—the Bay of Bengal being called the Tibetan Sea.

Mang-song Mang-tsen, the second son and successor of Song-tsen Gam-po, continuing the conquests of his father, subdued the Tatars around the Koko Nor (*Nor* is Mongol for *Lake*) in 663, and attacked the Chinese. After some adverse fortune the latter took their revenge and penetrated as far as Lhasa, where they burnt the royal palace Tsuk-tsen, the grandson of Mang-song and second in succession from him, promoted the spread of Buddhism. Tsuk-tsen married a Chinese princess who gave birth in 730 to Ti-song De-tsen, one of the three most illustrious monarchs of his country, partly on account of his conquests and partly because of the strenuous efforts he made in favour of Buddhism during his reign of forty-six years (743–789)

His son and successor Mu-ni Tsen-po enacted that there should be no distinction between humble and great After the third experiment the king's mother poisoned her son

Nothing of importance occurred during the following reigns, until that of Ral-pa-chen, who won glory by his care for the translations of the Buddhist scriptures which he caused to be completed, and rewritten more accurately In this reign a severe struggle took place with China, peace being concluded in 821. The line of kings ending with Ral-pa-chen is known as the "Religious Kings" (Chö-gyal), because they promoted Buddhism and were believed to be Incarnations of Chen-re-si, the patron deity of Tibet. And the greatest of them were Song-tsen Gam-po, Ti-song De-tsen, and Ral-pa-chen.

The proselytizing zeal of King Ral-pa-chen was too vigorous for many of his people When forty-eight years of age (A D 838) he was assassinated at the instigation of his own brother Lang-dar-ma, who was at the head of the anti-Buddhist party And now, as the chroniclers tell us, "The religious law broke like a rotten rope. The peace of Tibet became as a lamp without oil Evil arose like a storm; the good intentions were forgotten as a dream"

Lang-dar-ma was himself assassinated after a reign of only three years by a priest of the persecuted religion, who gained admittance to the King's presence under the pretext of showing him a new dance. The dance is represented in Tibetan religious plays to this day, in memory of this priestly retribution.

The Kingdom Divided.—Meanwhile, the kingdom was divided into eastern and western between Lang-dar-ma's two sons, the nation was disunited, and its glory among foreign nations waned. In 928 no one could be found at the Court of China who could read a Tibetan letter, which had been brought there by four priests.

The second western king, Pal Kor Tsen, left two sons, the latter of whom, Kyi-dé Nyi-ma-gon, went to Nga-ri, of which he made himself master and founded the capital, Pu-rang. He left three sons, of whom the eldest declared himself king of Mang-yül, the second seized Pu-rang, and the youngest Dé-tsuk-gön, became king of the province of Shang-shung.

The revival of Buddhism began with the two sons of the last-named, the elder of whom became a monk. The younger, Kor-ré, inherited his father's throne, and was followed in his authority by twenty successors. Ta-shi Tsek-pa, the elder of Pal Kor Tsen's sons, had three sons, Pal-dé, O-dé and Kyi-dé, each of whom with their descendants, made themselves masters of different districts. Thus the process of decentralization spread The kingdom was split up among a number of chieftains (some of them women), who built forts on hills and ridges overlooking their subjects on the plains below. And thus came into use the Tibetan saying:—

The fort on the hill,
The fields on the plain.

The fort protected the villagers and the villagers fed the fort.

Indian Religious Teachers.—Meanwhile, Buddhism was slowly reviving In A D 1013, the Indian pundit Dharmapala came to Tibet with several of his disciples. In 1042, a still greater came, Atisha, who left his monastery, Vikrama Sila, when 59 years of age, and came to Tibet, where he died fourteen years later He founded the Kar-ma-pa sect of Tibetan Buddhism, and wrote a number of works. He translated many other works, relating principally to Tantrik theories and practices Atisha is known in Tibet as "the Precious Lord" (Cho-wo Rim-po-ché)

Mongol and Chinese Influence.—The priests steadily increased their power during the twelfth and thirteenth centuries. One of the chief among them was the high priest of the large monastery of Sa-kya, south-west of Shi-ga-tse in central Tibet The grandson of the great Mongol conqueror, Jenghiz, invited the prelate of Sa-kya, known as the Sa-kya Pandita, to his court (1247) Five years later Kublai Khan, who had conquered the east of Tibet, and ascended the throne of China, invited to his court the Pandita's nephew, Pak-pa Gyal-tsen He remained twelve years with the emperor, and at his request framed for the Mongol language an alphabet imitated from the Tibetan, which, however, did not prove satisfactory, and disappeared after eighty-five years without having been very largely used In return for his services, Kublai invested Pak-pa with sovereign powers over (1) Tibet proper, comprising the thirteen districts of Ü and Tsang, (2) south-eastern Tibet (Kam) and (3) Am-do, a province in north-eastern Tibet From this time the Sa-kya-pa Lamas became the rulers of Tibet, and remained so, at least nominally, under 21 successive Lamas during seventy years (1270–1340)

When the power of Sa-kya began to wane, that of the rival monasteries of Dri-kung, Pak-dup and Tsal increased largely It was at this troubled epoch that Chang-chup Gyal-tsen, better known as Pak-mo-du from the name of his native town, appeared on the scene He subdued Tibet proper and eastern Tibet, and established a dynasty which furnished twelve rulers in succession, lasting till 1635, when the king of the Tsang province brought it to an end The latter was subdued a few years later by Gushi Khan, the chief of the Eleut Mongols. Th s dynasty of Pak-mo-du, known also as the Si-tya dynasty, brought prosperity

Rise of the Yellow Hats.—An admixture of Buddhism and Animism, and the lax priestly discipline that resulted, failed to satisfy the minds of its more ardent followers Reform came from within. In A D. 1358 there was born in Am-do one who was destined to play a large part in the national life of Tibet He was known as Tsong Ka-pa, "The Man from the Land of Onions." His disciples, known as the Yellow Hats and thus distinguished from the Red Hats of the existing priesthood, were forbidden to marry or drink wine, and a stricter code of morals was instituted He founded the large monasteries at Gan-den and Se-ra, which with Dre-pung are the three strongest religious bodies in Tibet.

Tsong Ka-pa's successor was Gan-den Trup-pa, who founded the great monastery of Tashi-Lhümpo, which in the seventeenth century became the residence of a Grand Lama—known to Europeans and Americans as the Tashi Lama—the second Grand Lama of the Yellow Church

Gan-den Trup-pa died in 1474, but his spirit was believed to have entered the body of a baby boy born two years later. This child became his successor, and thus there came into force the system of priestly incarnation There are nowadays some seven or eight hundred incarnate Lamas.

The second incarnation, and thus the third in the list, was Sö-nam Gya-tso, who spread the faith through Mongolia. From a Mongol chieftain he received the title of *Dalai Lama Vajradhara*, "The All-embracing Lama, the Holder of the Thunderbolt." And thus the title, Dalai Lama, came into use, and continues to-day.

THE RULE OF THE DALAI LAMAS

The fifth was Lob-sang Gya-tso, who in his contest with the older Church, received help from the Eleut Mongols to such good effect that he was established in 1641 as the Ruler over the whole of Tibet.

The Potala Palace, emblem of sovereignty, had been built by the great king, Song-tsen Gam-po, but destroyed during subsequent wars. The fifth Dalai Lama's chief Minister built the great stone palace on a larger scale, which with but few additions, stands to this day It is nine hundred feet in length, and higher than St. Paul's Cathedral in London, but harmonious in line and colour.

The fifth Dalai Lama visited the Emperor of China at Peking. He was received as an independent sovereign, for the Lama's position, backed by Mongol support, and his religious authority among both Mongols and Manchus ensured for him the highest treatment at the hands of the Manchu Emperor and Court.

It was during the early life of this Priest King that the first European entered Tibet. His name was Antonio de Andrada, a native of Portugal. He did not reach Lhasa or Shigatse. The first Europeans to enter Lhasa were two Jesuit fathers, Grueber, an Austrian and D'Orville, a Belgian, who left Peking in 1661, travelled by the Koko Nor to Lhasa, stayed there a month, and then came to Nepal In Lhasa they witnessed the rule of the fifth Dalai Lama, whom Grueber styles "the devilish God-the-Father who puts to death such as refuse to adore him" But among Tibetans the fifth is accounted as the greatest of all their Dalai Lamas. The present day administration of Tibet dates in large measure from his reign, and stories are told not only of his ability but also of his benevolence.

The Great Fifth, as he is generally known, died in 1680, but Sang-gye Gya-tso was unwilling to desist from his task He concealed the death and ruled in his master's name. In due course, however, a successor, who had received the name of Tsang-yang Gya-tso, succeeded to the headship of Tibet.

The new Dalai was entirely unorthodox. He wrote light verse too which remains popular to this day among Tibetans.

But his own contemporaries did not view Tsang-yang Gya-tso in that light Many Tibetans, Mongols and Chinese doubted whether he could be a real incarnation of the divine spirit of Chen-re-si which dwelt in all true Dalai Lamas. The Chinese and Mongols removed him from Lhasa on the understanding that he was to visit Peking and put him to death at Nag-chu-ka, ten days' journey north of Lhasa Dissensions among the people followed, and the Chinese were able to increase their hold over Tibet, always to China a matter of prime importance by reason of the religious authority exercised by the Dalai Lama in Tibet, Mongolia and Manchuria.

During the early years of the eighteenth century the Chinese established a representative known as Amban, and later on two such representatives, in Lhasa. These intervened in Tibetan administration. In 1750, the Ambans killed the Tibetan Regent. The people in their turn massacred the Chinese in Lhasa. The Emperor Chien-lung dispatched an army, restored Chinese authority, and strengthened the power of the Ambans. But Lhasa is so far from the Chinese frontier that it was an uphill fight.

Gurkha Invasion.—In 1788 the Gurkhas, who had recently gained the ascendancy throughout Nepal, occupied some Tibetan districts near the Nepal frontier Three years later they captured Shi-ga-tse. The Chinese Government, now thoroughly aroused, dispatched an army, composed partly of Chinese and partly of Tibetans, under Chinese leadership. This army marched through Tibet in the arctic cold of winter, defeated the Gurkhas decisively during the spring of 1792, and dictated terms of peace within a short distance of Katmandu, the Gurkha capital. Suspecting also that the British, who were by then established in India, had helped the Gurkhas, the Chinese closed Tibet as far as possible to foreign influence. It was decreed that all foreign questions should be dealt with by the Ambans, not by the Tibetan Government.

In 1841, a force of 5,000 Dogras, mountaineers from Kashmir, invaded western Tibet, but were defeated by the Tibetans and almost exterminated. A battle was fought at 15,000 feet above sea level in the depths of winter, and the great cold contributed largely to the defeat of the Dogras.

Another Gurkha invasion occurred in 1855, and this was more successful. The resulting treaty empowered the Gurkhas to establish an Agency in Lhasa and other centres, gave them an annual subsidy of ten thousand rupees, the right of free trade in Tibet, and the right of extra-territoriality In return the Gurkha Government undertook to aid Tibet if the latter were attacked by another nation

EXPLORATION

There is no gradual blending of the climates and physical conditions of India and Tibet, such as would tend to promote intercourse between the inhabitants of these neighbouring regions On the contrary, there are sharp lines of demarcation, both in the mountain barrier which is scalable at comparatively few points, and also in the social aspects and conditions of life on either side. No great armies have ever crossed Tibet to invade India

Jesuit and Capuchin Visitors.—It was no easy matter for the early European travellers to explore Tibet. Friar Odoric of Pordenone is supposed to have reached Lhasa *c.* 1328, but this visit is doubtful The Jesuit Antonio de Andrada, a native of Portugal (1580–1634), travelling from India, appears to have entered Tibet on the west, in the Manasarowar Lake region In 1661 Grueber and D'Orville, as mentioned before, reached Lhasa The extracts from Grueber's narrative, given by Athanasius Kircher in his *China illustrata* (Amsterdam, 1667), are accompanied by a good drawing of the Potala During the first half of the 18th century various Capuchin friars appear to have passed freely between Calcutta and Lhasa (1708), by way of Nepal. They even founded a mission in Lhasa, which, after failing at first, was more firmly established in 1715

In 1716 two Jesuits, P Ipolito Desideri, of Pistoia, and P. Freyre, a Portuguese, reached Lhasa by way of Kashmir. The long journey from Kashmir was taken by Lake Manasarowar and the valley of the Tsango-po Desideri remained at Lhasa till April 1721, witnessing the capture of Lhasa successively by Dzungar and Chinese Of the moderation of the latter, and their abstinence from all outrage or plunder, he speaks highly He left a large MS volume of his observations The next European visitor was Samuel Van de Putte, of Flushing, an LL D. of Leiden, whose thirst for travel carried him through India to Lhasa (1730), where he is said to have resided a long time.

In 1745 the Capuchin mission finally collapsed after a revival had been attempted in 1741 by a party under Orazio della Penna. The collapse appears to have been due to lack of funds rather than Tibetan opposition We possess some of the results collected by this mission in an excellent short treatise on Tibet by P. Orazio himself, as well as in the *Alphabetum Tibetanum* of the Augustine monk A. Georgi (Rome, 1762). Some fifty volumes, the relics of the mission library, were in 1847 recovered from Lhasa by Brian Hodgson, through the courtesy of the Dalai Lama himself, and were transmitted as an offering to Pope Pius IX.

First English Visitation.—The first Englishman to enter Tibet was George Bogle, a writer of the East India Company, in 1774, on an embassy from Warren Hastings to the Tashi Lama. In 1783 Lieut Samuel Turner was despatched on a mission similar to that of Bogle, and reached Shigatse In 1811–1812, an English traveller, Thomas Manning, reached Lhasa. Having resided some years at Canton, Manning went to Calcutta, bent on reaching the interior of China through Tibet, since from the seaboard it was sealed After reaching Lhasa he stayed there about five months, and had several interviews with the Dalai Lama, but was compelled to return to India. He never published anything regarding this journey, but some years after his death extracts from his scanty and eccentric private diary were published. These, however, do not yield much information.

The Abbé Huc states that William Moorcroft, an Englishman who made a journey into Tibet in the neighbourhood of Lake Manasarowar in 1812, and another into Kashgar in 1824, lived in Lhasa for twelve years disguised as a Muslim.

Exclusion of Europeans.—During the 19th century Europeans were systematically prevented from entering the country, or speedily expelled if found in it. In 1844–1846, however, the

French missionaries, Evariste Régis Huc and Joseph Gabet, made their way to Lhasa from China. They travelled via Siningfu, and arrived in Lhasa on the 29th of January 1846. On the 15th of March they were sent off under escort by the rugged road to Szechuen Huc's book, *Souvenirs d'un voyage*, etc, is a most delightful book of travel. The brothers Henry and Richard Strachey visited Manasarowar Lake in 1846 and 1848 respectively. In 1866 the Abbé Desgodins travelled through portions of eastern Tibet and reached Cham-do (in Kam)

Indian Explorers.—From 1863 onwards a number of Indian explorers were sent by the Government of India into Tibet, for the purpose of surveying the country and collecting information about its inhabitants They carried prayer wheels, but instead of prayers these contained rolls of blank paper on which observations were noted. They carried also Tibetan rosaries by the beads of which each hundred paces were counted. The work was dangerous and difficult, but the results were on the whole remarkably accurate. The best known of these men were Pandit Nain Singh, Pandit Krishna, originally known as A-K (from the first and last letters of his name transposed) and U-gyen Gya-tso, or U-G. Nain Singh reached Lhasa in the course of two remarkable journeys. In the first, after an ineffectual attempt by Nepal, he travelled by the Manasarowar Lake, and the road thence eastward, parallel to the course of the Tsangpo, reaching Lhasa on the 10th of January 1866, and leaving it on the 21st of April 1867 On the second journey (1874) he started from Ladak, crossing the vast and elevated plateau by the Tengri Nor and other great lakes, and again reaching Lhasa on the 18th of November

In 1878 A-K. also visited Lhasa, stayed a year, and afterwards continued into Tsaidam, not returning to India till 1882. U-gyen Gya-tso, a Tibetan of Sikkim, who was originally a teacher of Tibetan in a Darjeeling School, secured permission in 1879 from the Tashi-lhunpo authorities for Sarat Chandra Das, Bengali schoolmaster at Darjeeling, to visit that monastery, where his name was entered as a student. This was the opportunity for a series of valuable exploratory journeys through the Tibetan provinces adjoining the Indian and Nepalese frontiers. Sarat also brought back from his journeys a large number of interesting books in Tibetan and Sanskrit, some of which were edited and published by him, with the assistance of U-gyen Gya-tso and other Tibetans But these explorations, and particularly those of Sarat, when discovered by the Tibetans, incensed them still further, and deepened their distrust of the strong Power that came nearer and nearer and now explored their country in secret

The Russian explorer Prjevalsky, although he did not penetrate far into Tibet, did much towards determining the conformation of its north-eastern and eastern mountain systems His fourth journey, between November 1883 and October 1885, covered part of northern Tibet, and established the true character of Tsaidam.

Recent Exploration.—Between 1889 and 1892, W. W. Rockhill, an American possessing great qualifications for Tibetan exploration by reason of a fair knowledge of the language and history of the country, coupled with the instincts and training of a scientific explorer, made two journeys through the north-eastern and eastern districts of Tibet. His record of these has added to the world's knowledge both of the country and its people.

In 1889 Prince Henri d'Orleans and M. Bonvalot; in 1891 two Englishmen, Capt Bower and Dr. Thorold; the following year Miss Taylor, a solitary Englishwoman who came to within 150 miles of Lhasa, and in 1893, two other Frenchmen, MM. Dutreuil de Rhins and Fernand Granard, all entered Tibet They were followed by Mr. and Mrs. Littledale, accompanied by Mr. Fletcher, in 1895; by Capt. Deasy a year later, by Capt. Welby and Lieut Malcolm in the same year, and by Rijnhart, a Dutch missionary, in 1898 and by Sir Aurel Stein. These all explored different tracts in the great unexplored regions, and many brought back knowledge of the flora and fauna. All, or nearly all, endeavoured to reach Lhasa, but none succeeded, so thorough were the precautions taken by the Tibetans to guard against such an event. The Littledales came the nearest, being stopped 80 miles north of the Forbidden City. De Rhins and Rijnhart lost their lives, being murdered, as is believed, by the people of the country.

Dr. Sven Hedin, a Swede, has made three important journeys in Tibet and has traversed the country, north, south and west, surveying a great deal of unexplored country. His attempt to reach Lhasa, as that of all Europeans during these days of Tibetan hostility, was frustrated by Tibetan watchfulness But his careful and detailed maps and lake soundings, and his scientific observations, hydrographic, geological and meteorological, have placed him in the forefront of modern explorers. (X.)

MODERN HISTORY

In 1774 and 1783 Warren Hastings, the far-sighted Governor-General of India, had established transient connection with the Tashi Lama. From 1872 onwards the Government of India made attempts to open up relations with the central Tibetan Government. But the latter declined, for they feared and distrusted the Power whose strength and influence were steadily extending in the territories on their southern frontier. A treaty made in 1890 between India and China was repudiated by the Tibetans

In 1903, as a result of continued disputes, and in particular from the fear of Russian penetration, the Indian Government despatched a mission with an armed escort to Tibet The Tibetans, however, refused to negotiate, and the Chinese were powerless In 1904 the mission advanced further into the country. It was opposed, and fresh troops were sent, so that it became a military expedition It withstood the rigours of the climate, dispersed without much difficulty the Tibetan levies, who were untrained and poorly armed, and succeeded in reaching Lhasa Lt-Col (now Sir Francis) Younghusband, the political representative with this force, effected a treaty there in September 1904 with the Tibetan delegates, the Dalai Lama and his entourage having fled to Mongolia After modification by a Convention with China in 1906, the main terms of the Lhasa treaty were —

(a) The opening of two fresh marts to foreign trade, one at Gyantse between India and Lhasa, and one at Gartok in western Tibet.

(b) The abolition of trade dues between Tibet and India

(c) Tibetan territory not to be ceded, leased, etc, to any Foreign Power.

(d) An indemnity of two-and-a-half million rupees (£166,000)

Chinese Suzerainty.—The Anglo-Russian Convention of 1907 recognized Chinese suzerainty over Tibet, and stipulated that neither Russia nor Britain should interfere in the internal administration of Tibet, seek concessions there, take any part of the revenue, or depute representatives to Lhasa But, as a result of the Russian Revolution, this Convention is believed to be no longer in force

The Chinese Government were alarmed by the British Expedition to Lhasa in 1904, fearing a repetition and the establishment of British power there. The Peking Convention of 1906 and the Anglo-Russian of 1907 placed them in a strong position Tibet was enfeebled by the British attack, and perhaps somewhat mazed by the crowd of events. So China organized a military Expedition of her own, which eventually, in February 1910, reached Lhasa

The Dalai Lama and his Government fled again, this time to Darjeeling in India. Here the British Government treated them hospitably, and being on Indian soil, they were safe from personal attacks by the Chinese, who contented themselves with consolidating their position in Tibet While observing strict neutrality as regards Tibet, Britain took occasion to inform China that she would tolerate no interference with the Himalayan States, Nepal, Sikkim and Bhutan.

Recent Developments.—Tibet's deliverance, however, was near at hand. In 1911 the Chinese Revolution broke out, disorder among the Chinese troops ensued, and the Tibetans were able to drive them out of Lhasa, and to recapture most of their country. The Dalai Lama and his Ministers returned to Lhasa. They were now hostile to China, and friendly to Britain. In 1917 the Chinese attacked again, but were defeated, and the Tibetans pushed them back more or less to the positions which had been held since 1720.

During 1912 Russia, by a treaty with Mongolia, gained further influence in that country. The following year a conference was

held in India by Britain, China and Tibet to discuss the political status of Tibet, but achieved no decisive result.

Then followed the World War. The Tibetan Government offered a thousand soldiers to fight on the British side, a striking change from their former attitude of hostility.

Towards the end of 1920 Mr. (afterwards Sir Charles) Bell, the British representative in Tibet, was deputed to Lhasa at the request of the Tibetan Government, the first white man to be invited to Lhasa by the Tibetans themselves As a result of his visit, which lasted for about a year, the growing friendliness between the two nations was still further strengthened, and a line of policy consonant with that attitude was marked out In 1922, following the repeated requests of the Tibetan authorities, the Forbidden City of Lhasa was linked with India by telegraph.

Mount Everest.—Permission was obtained for the Royal Geographical Society of England to despatch a climbing expedition to Mount Everest through Tibetan territory Three such expeditions followed, in 1921, 1922 and 1924 respectively The last attained to within 800 feet of the summit. Mallory and Irvine, two of the climbers, lost their lives in the last attempt. Since 1912, Tibet has been politically independent of China

TIBETAN ART. Tibetan art is to a large extent a continuation of the mediaeval Buddhist art of Behar and Orissa, the dominions of the Pala kings, which were the strongholds of Indian Buddhism during the 11th and 12th centuries. The conservatism which is so marked a feature of Tibetan art is due to the peculiar character of that rude and uncultivated country, which Buddhism reached, late and in a very decadent form, in the 7th century A D. The barbarians beyond the mountains were all the more willing to receive the pious images, so accurately representative of the religious spirit, which the missionaries brought from India, because they had no local artistic tradition to set up against them All that they could do was to have copies made of the original models, which were deeply venerated, and then in turn to copy them for themselves. Of all the copies thus made, the most servile were the reproductions of paintings This was due to purely technical reasons; the copies were executed by anonymous artisans by means of transfers It is thus extremely difficult for the historian of art to decide the date of paintings of this kind. The bronzes are less puzzling, since many of them are cast by the method *à cire perdue,* and consequently have more originality and indeed individuality. Architecture, although to a large extent determined by the climate and the nature of the soil, shows Indian and Chinese influences. Though situated between these two countries of ancient and highly developed civilisation, and subjected to their influence, Tibet, as the great refuge of Indian Buddhism, enjoyed so great a religious prestige that it exported certain aspects of its religious art to the China of the Ming and Tsing emperors.

Temple Banners (thang-Ka).—These paintings are for the most part reproduced by means of transfers, a method used in embroidery. The transfers are applied on a piece of cotton, canvas, or more rarely silk, which has first been treated with a coating made of a mixture of glue and chalk-dust, completely smoothed by rubbing with the polished part of a sea shell Thin silks which will not take a coating of this kind are given to experienced craftsmen who copy direct from the model without using a transfer.

Attempt at Chronological Classification.—It will be seen from the description of technical processes given above that it is an extremely difficult matter to date a Tibetan painting, unless the subject of the picture gives some chronological indication. The main interest of a study of Tibetan paintings thus resides in a just appreciation of the antiquity of the subject represented rather than of that of the painting. One of the most ancient subjects is that treated by the somewhat rare paintings which represent the Bodhisat Siddharta, the future Buddha Śâkya-muni, in the form of a young man. This is probably a pictorial representation of the celebrated statue which Sarat Chandra Das saw in the principal temple of Lhasa, this statue will be dealt with later in the section dealing with sculpture There are certain pictures representing the life of the Buddha Śâkya-muni, some of the many reproductions of which are to be seen in various European museums, which are derived from Indian originals of the 9th and 10th centuries. Some of the pictures representing the birth of the Bodhisat are strongly reminiscent of Indian models The compositions based on ancient originals deal only with the principal episodes in the life of the Buddha Taking their inspiration from these models, Tibetan artists of about the middle of the 18th century composed an abundantly illustrated life based on a biography dating from 1734 In these more modern pictures, however, the scenes, of which there is an infinite variety, are all represented round a central figure of the Buddha. In short, Tibetan illustrations of the life of the Buddha may be traced to two sources, the first very ancient (9th to 10th centuries), the second composed entirely by a Tibetan lama of the 18th century. The paintings of the second series show elements derived from Chinese landscape painters in the representations of scenery, rocks are rendered by the superposition of uniform coats of blue and green, separated by gold lines Other compositions unmistakably go back to Indian originals Among these are the representations of the 84 great sorcerers, whose cult had been spread by means of Lamaism beyond the borders of Tibet itself The method of representing the eighty-four sorcerers was already fixed in the 13th century, for M P. Pelliot has discovered pictures representing them in a cave of Tuen-Huang (province of Kan-su in Western China) which was decorated during the Mongol period The Tibetan representations of these great magicians (Musée Guimet) are clearly derived from the great Indian tradition

The representations of the Bodhisats are directly reminiscent of the artistic traditions which were prevalent in Orissa in the time of the Pala kings, who were the last champions and patrons of Indian Buddhism A Tibetan painting discovered at Tuen-Huang by Sir Aurel Stein, which is probably the most ancient extant Tibetan picture (*c.* 10th century) represents Avalokiteśvara, whose mission it is to liberate humanity from the Eight Great Perils This painting, which is now in the British Museum, shows a definite affinity with an Avalokiteśvara in the Fine Arts Museum of Boston which A K. Coomaraswamy believes to be an Indian work of the Pala or Sena period (12th century). So great is the conservatism of Tibetan artists that very little difference can be observed between the 10th century painting discovered by Sir Aurel Stein and a similar composition of modern date which was brought from Tibet by Jacques Bacot and is now in the Musée Guimet. (*See* INDIAN AND SINHALESE ART AND ARCHAEOLOGY)

The influence of the Indian tradition—it is possible to go further and say of the Ajantâ tradition—is particularly marked in a painting in the Musée Guimet representing the Bodhisats Avalokiteśvara and Kshitigarbha seated in an attitude of royal ease

Tibetan artists never introduced any innovations in the representation of the fierce, terrible and threatening deities which derive from Śiva (*Mahākâla*). Divinities of this kind are not to be found in the most ancient compositions which depict episodes from the life of the Buddha Śâkya-muni, the most that appears from time to time is a genius (*yaksha*) subduing heretics All other paintings, whether their subjects are Bodhisats or saints, include representations of fierce deities, often accompanied by their female counterparts. Pictures of this kind already existed in India, but the Tibetans greatly developed the cult of these deities of Saivite origin. The Manchu Emperors who ruled over China in the 18th century appear to have had a special taste for pictures of this kind, and Tibetan Buddhic art had great vogue at Peking at the end of that century. Paintings ordered by the Emperor Chien-lung and executed at Peking under direction of the Grand Lama of Peking are extant. One of them represents the fierce goddess Sridevî (*Lha-mo*); it is carried out in the purest Tibetan style

except that there are certain details of execution which are clearly Chinese, especially in the treatment of the mule on which the goddess is mounted and the emblems with which the frame of the picture is adorned This is a good example of Lamaist painting dated 1777, which, though executed in China, shows, with the exception of certain details, all the characteristics of Lamaist works of art. An inscription in four languages, Chinese, Mongol, Manchu and Tibetan, says: "In the forty-second year of Chien-lung, an Imperial decree was issued ordering the lchang-skya-hu-tog-thu (Grand Lama of Peking) to draw holy images, following the text of the sacred books, in order to do homage to the auspicious goddess Śrîmatî (Śrîdevî) . ." A considerable number of religious pictures were executed during the reign of the Emperor Chien-lung by Tibetan lamas at Pekin, and special mention should be made of the paintings showing definite Tibetan characteristics which represent the divinities of Confucianism and Taoism.

To return to the normal work of Tibetan artists, it is necessary to mention a number of paintings representing the saints of Indian Buddhism and Lamaism The clearly marked Indian influence visible in the pictures of the group of the great sorcerers has already been mentioned; the same influence, becoming gradually attenuated, may be seen in the series of pictures showing the life of some great saint, such as the famous Atiśa, who died in A D. 1058 (Pl. II, fig 1.), or the lchang-skya Rol-pa'i rdo-ye (Lalitavasjra) (1736–95), the same who had the picture of the goddess Śrîdevî painted at the order of the Emperor Chien-lung The latter is not an ancient composition; both the subject and the painting itself are modern, and show the characteristic Tibetan architecture of the monasteries of Dgah-ldan and Bra-śis lhun-po (Tachilhunpo), placed on rocks treated in a way which shows Chinese influence (*see* at the top and in the middle the monastery of Brag-dkar [White Stone]) The saint, who is seated in the European fashion in the middle of the picture on the right, carries the book and sword, the attributes of his patron the celebrated reformer Tsong Kha-pa (A.D 1355–1417). These attributes are also those of Manjuśri, the Bodhisat of transcendental wisdom, who inspired Tsong Kha-pa It is for this reason that a magic representation of Manjuśri appears in the centre of the painting under the aspect of the fierce Yamântaka with the head of a bull Maitreya, the future Buddha, is shown in a medallion placed in the upper part of the picture on the left The saint himself appears, after his death (at the top of the picture on the right) in the trifoliate niche of a *stupâ;* he is being mourned by his disciples, and divinities are rising from the clouds to receive him. The painting showing the learned Atiśa (11th century) is less elaborate, and is clearly derived from a more ancient original.

Tibetan artists sometimes use a technique similar to that of wax painting; some remarkable examples of this method are to be seen in R. Pfister's collection It is a highly successful attempt to find relief from the monotony of the flat tones of tempera painting; the faces stand out remarkably clearly, and the floral decorations show great originality in the choice of colours The painting is unfortunately damaged by the imprints of the hands and feet of the Grand Lama of Bra-śis lhun-po (Tachilhunpo). The painting represented in Plate II, fig 3, shows the fifth Dalai-Lama Ngag-dbang Blo-bzang-rgya-mcho (1617–80); special note should be taken of the delicacy of the floral decoration

The Tibetans also have a special fondness for paintings representing particularly venerated places One of these pictures shows, in a sort of rough perspective, the principal religious edifices of Lhasa; in the centre the Potala, in the lower part the great temple (Jo Khang), in the upper part the monasteries of Sera and Depong, which are two miles away from Lhasa, and a number of small shrines treated in the minutest detail.

Bon-po Paintings.—Before leaving the subject of Tibetan painting, it is fitting to mention the paintings which appear in the temples of the Bon-po, the followers of the pre-Buddhic religion of Tibet. The rare specimens of Bon-po painting which we have had an opportunity of studying are, as far as the legends represented are concerned, nothing more than imitations of Lamaist paintings. The trained eye can, however, clearly distinguish between Bon-po and Buddhist paintings Bon-po paintings scarcely ever contain a large-scale figure of the hero of the legend the episodes of which are represented by the picture Thus the paintings illustrating the legend of the Bon-po prophet Gśen-rab-mi-bo (Ollone collection) consist only of a series of miniature scenes.

Buddhic Sculpture.—According to legend, the most ancient Buddhic sculpture which was imported into Tibet came from Magadhâ, but it is said to have reached Tibet through China, having been brought by the princess of Wen-tcheng, who was related to the Emperor Tang Tai-tsong and married the 1st Buddhist king of Tibet, Srong bcan sgam-po (7th century A.D.). This statue still exists in the Jo-Khang of Lhasa, and forms, together with another statue of the monastery of Kum-bum and the famous image of the Santal temple at Peking, one of a triad celebrated in the Buddhist world. The Lhasa statue is probably of the same type as that which is preserved in the temple of Seiryo in Japan. A distinguishing feature of that work of art is the characteristic drapery with its close folds. A statuette in the Musée Guimet, though a comparatively modern work (18th century) (Pl. I., fig. 6) recalls these ancient originals Most of the Tibetan statues to be seen in Europe are modern, but it is possible to trace back their origin, through a number of modifications, to Indian sculptures executed at the time of the Pala kings of Bengal (11th to 12th centuries A D) The traces of Chinese influence which may here and there be noted are to be attributed to the Tang or even the Sung period. These statuettes, most of which are cast by the process known as *à cire perdue,* represent only a portion of the whole production of the skilled Tibetan metal-workers There are also a number of bronze statues 10 or 12 metres high representing the Bodhisat Avalokiteśvara with 11 heads Occasional examples are found which have no counterpart in the Buddhic world, such as the Bodhisat who is shown making a mystic gesture which is nowhere else represented (Pl I, fig 8) Of three representations of the same divinity, one may show Chinese and one Indian influence, while the third is purely Tibetan This applies to three representations of Manjuśri which are preserved in the Musée Guimet; the first figure, which is brandishing a sword, is in the classical Indian style, the second, which is loaded with ornaments and is heavy of aspect, is Tibetan, while the third is a young Chinese prince, carelessly seated in an attitude of royal ease, his hand resting on a book. The statuettes of saints are in some cases actual portraits (Pl I, fig. 3).

Wood-carving.—The finest examples of Tibetan craftsmanship are the bronzes and brasses, but there are also some fine statues carved in wood. The wood-carvers, however, excel most of all in the execution of low reliefs adorning the rectangular pieces of wood which are used to cover the sacred books. These reliefs show extraordinary technical skill

Bon-po Sculptures.—Very few Bon-po sculptures have as yet been studied. They are very bad specimens, and are influenced by late Chinese statuary

Iron Work; Gold- and Silversmiths' Work.—Some of the Tibetan metal workers are magnificent artists Some of the designs of iron work are as delicate as lace; dragons, volutes and geometrical patterns are mingled in detailed and balanced designs ornamenting saddles, pen-cases, quivers and clasps for reliquaries (central motif: daśâkâro vaśî). Some of the reliquaries are carried out in beautiful repoussé work in silver and sometimes, also in gold. Beautiful brass vases and censers are also executed in repoussé work. The designs on these vases are sometimes Indian and sometimes Chinese in character Damascene work is very much used for the decoration of pen-cases. Tibetan jewellery, heavily set with turquoises, includes earrings, necklaces and bracelets (*See* SILVERSMITHS' AND GOLDSMITHS' WORK.)

Architecture.—The available information concerning Tibetan architecture is very incomplete. No complete studies of monasteries with plans have been made except in the case of Kum-bum.

Stûpas of the Tibetan type have a characteristic form of their own; the base is raised to such a height that it sometimes shelters a little shrine, the bulb-shaped dome is sometimes very small, and the discs of the parasols, which are very close together, form a cone surmounted by the crescent and the disc. The base and the disc are of masonry, and the upper part of gilded copper. The

EXAMPLES OF TIBETAN ART

1. Religious vessel of gold, silver and copper used only by holy Lamas. 2. Samantabhadra Bodhisattva, Genius of Goodness, on her vehicle, the elephant. Made of bronze and gilded. 3. Statuette of Padma Sambhava, the Buddhist pandit who came to Tibet from India in the 8th century, and translated parts of the Buddhist scriptures into the Tibetan language. 4. Another view of Samantabhadra Bodhisattva on her elephant. 5. A religious vessel of gold, silver and copper inlaid with turquoise and showing Chinese influence. 6. Figure of the Lama Jigs-med-rgya-mcho. 7. Figure of Bodhisattva wearing a diadem of five Dhyani-Buddhas. 8. The Bodhisattva Siddhārtha (Gotama Buddha), founder of Buddhism, in characteristic teaching attitude. 9. Figure of Lha-mo. 10. Delicately carved gateway. Tibetan design. 11. The Bronhyd Lotus, the perfect eight-leaved lotus flower with silver urn in centre. The lotus represents the heart of beings and the urn holds the source of organic life. 12. Bronze statuette of Nepalese lion (inscribed under neck). 13. The lotus shown Fig. 11., with all petals closed. 14. A Buddhist incense burner with pierced cover

TIBETAN ART

TIBETAN FAINTINGS

1. Painting of the learned Atisa. Figure of naked heretic near the halo, together with the figures of a sorcerer and his disciples, is reminiscent of Indian art. Numerous visits of this saint are represented by miniature scenes. At the top of picture (to the right of the aureole) he is seen acting as mediator between two armies about to fight

2. Representation of lchang-skya Rol-pa' i rdo-ye. Chinese influence shown by architecture of the monasteries in painting. The saint carries a book and sword, attributes of his patron, the celebrated reformer, Tsong Kha-pa

3. Painting of the fifth Dalai-Lama Ngagdbang Blo-bzang-rgya-mcho. He carries the thunderbolt and bell of the Buddha Vajradhara. Disciples and seven jewels are picturesquely grouped at bottom of picture

temples (*cf.* plan of Jo Khang in Waddell's *Lhasa and its Mysteries*) are frequently built on a rectangular ground plan with a sort of ambulatory between the outside wall and the chapels opening on the main temple. The main temple altar is at the end opposite to the entrance, and the principal temple is roofed with Chinese pavilions. The monotony of the massive structure of the palaces and castles is relieved by plaster-work of violent colours such as deep vermilion; large tapestries representing religious subjects are hung out on solemn occasions (*See* also INDIAN ARCHITECTURE.)

TIBETAN LANGUAGE. The language of Tibet is known as "the speech of Bod or Tibet" namely *Bod-skad* (pronounced Bhö-kà), while the vernacular is called *P'al-skad* or "vulgar speech," in contradistinction to the *rje-sa* or "polite respectful speech" of the educated classes, and the *ch'os-skad* or "book-language," the literary style in which the scriptures and other classical works are written

It comprises several dialects classed into three groups, (1) the central or the dialects of Lhasa and the central provinces of Ü and Tsang (including Spiti) which is the *lingua franca* of the whole country, (2) the western dialects of Ladak, Lahul, Baltistan and Purig, and (3) the eastern dialects of the province of Khams. Many sub-dialects of Tibetan are spoken in the frontier Himalayan districts and states outside Tibet The Takpa of Tawang in the eastern Assam Himalayas appears to form a transition between the central and the Sifan group of dialects on the Chinese frontier, which includes the Minyak, Sungpan, Lifan and Tochu dialects. On the north bordering on Turkestan the dialect of the nomadic Hor-pa tribes is much mixed with Turkic ingredients

Tibetan is allied to the Burmese languages, and forms with the latter the "Tibeto-Burman" family

Writing.—Notched sticks (*shing-chram*) and knotted cords were in current use On the eastern frontier the medicine-men or *tomba* of the Moso have a peculiar pictorial writing, which is known in Europe from J Bacot's work, *Les Mo-So* (Leyden, 1913). It undoubtedly contains survivals of a former extensive system superseded by the alphabetic writing introduced from India The close resemblance of the Tibetan characters "with heads" to the Gupta inscriptions of Allahabad shows them to have been derived from the monumental writing of the period; and the other Tibetan letters came from the same Indian character in the style in which it was used in common life. The Tibetan half-cursive was further developed into the more current "headless" (*u-med*) characters, of which there are several styles. The ancient manuscripts discovered by Sir Aurel Stein in Khotan include very early Tibetan documents.

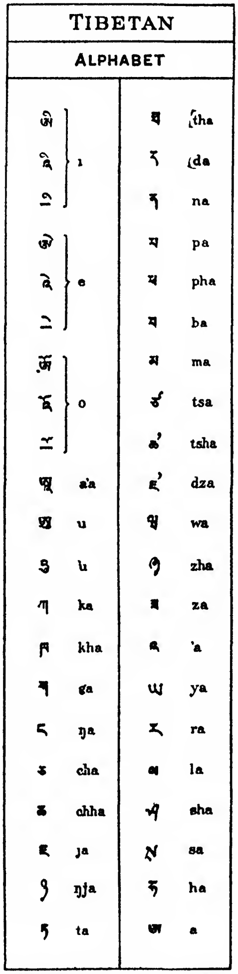
The language was first reduced to writing with the assistance of Indian Buddhist monks in the middle of the 7th century A D. by Thonmi, a Tibetan layman. The letters, which are a form of the Indian Sanskrit characters of that period, follow the same arrangement as their Sanskritic prototype. The consonants, 30 in number, which are deemed to possess an inherent sound *a*, are the following: *ka, k'a, ga, nga, ča, č'a, ja, nya, ta, t'a, da, na, pa, p'a, ba, ma, tsa, ts'a, dza, wa, z'a, za, 'ha, ya, ra, la, s'a, sa, ha, a;* the so-called Sanskrit cerebrals are represented by the letters *ta, t'a, da, na, s'a,* turned the other way. *Ya,* when combined as a second consonant with *k-, p-, m-,* is written under the first letter. *Ra,* when combined as second letter with *k-, t-, p-,* is written under the first, and when combined with another consonant as first letter over the second. The vowels are *a, i, u, e, o,* which are not distinguished as long or short in writing, except in loan words transcribed from the Sanskrit, etc., though they are so in the vernaculars in the case of words altered by phonetic detrition. By adding to the bases form-words as prefixes, suffixes or infixes, the Tibetan language has developed a considerable grammatical system. Agglomerations of consonants are often met with as initials, giving the appearance of telescoped words—an appearance which historical etymology often confirms. Many of these initial consonants are silent in the dialects of the central provinces, or have been resolved into a simpler one of another character. The language is much ruled by laws of euphony. Among the initials, five, viz., *g, d, b, m, 'h,* are regarded as prefixes, and are called so for all purposes, though they belong sometimes to the stem As a rule none of these letters can be placed before any of the same organic class. Post-positions, *pa* or *ba* and *ma,* are required by the noun (substantive or adjective) that is to be singled out; *po* or *bo* (masc) and *mo* (fem.) are used for distinction of gender or for emphasis. The cases of nouns are indicated by suffixes, which vary their initials according to the final of the nouns. The plural is denoted when required by adding one of the several words of plurality. When several words are connected in a sentence they seldom require more than one case element, and that comes last There are personal, demonstrative, interrogative and reflexive pronouns, as well as an indefinite article, which is also the numeral for "one" The personal pronouns are replaced by various terms of respect when speaking to or before superiors and there are many words which are only employed in ceremonial language. The verb, properly a kind of noun or participle, has no element of person, and denotes the conditions of tense and mood by an external inflection, or the addition of auxiliary verbs and suffixes when the stem is not susceptible of inflection, so that instead of saying "I go" a Tibetan says "my going." The chief differences between the classical language of the Tibetan translators of the 9th century and the vernacular, as well as the language of native words, existed in vocabulary, phraseology and grammatical structure, and arose from the influence of the translated texts

Tones.—Tones in Tibetan have developed on the same lines as in Chinese Thus intransitive bases seem to have begun only with soft consonants, and it is doubtful whether the parent tongue possessed hard consonants at all, while transitive bases were formed by hardening of the initial consonants and at the same time pronouncing the words in a higher tone, and these two latter changes are supposed to have been indicated by a prefix to the base-word Many of these old soft initial consonants which are now hardened in the modern dialects are preserved in classical Tibetan, *i e.*, in Tibetan of the 7th to the 9th century A D.

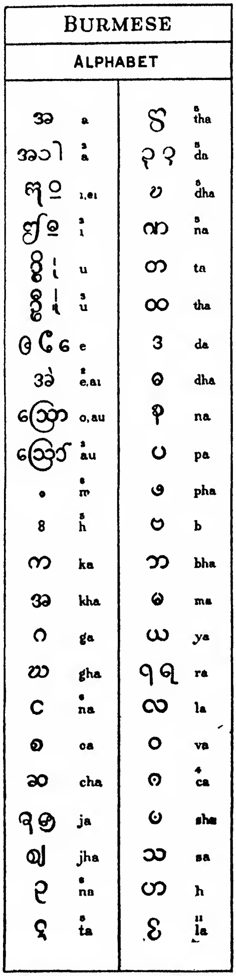
See Sarat Chandra Das' *Tibetan English Dictionary with Sanskrit synonyms* (1902), V. C Henderson, *Tibetan Manual* (1903); and Sir C. A. Bell, *Grammar of Colloquial Tibetan* (Calcutta, 1919), and *English-Tibetan Colloquial Dictionary* (1920); also vol iii of the *Linguistic Survey of India* (1908). As separate publications there are several vocabularies of Chinese and Tibetan, Mongol and Tibetan, Chinese, Manchu, Mongol, Oelot, Tibetan and Turkish, Tibetan, Sanskrit, Manchu, Mongol and Chinese

TIBETO-BURMAN LANGUAGES. The Tibeto-Burman family comprises dialects spoken from Tibet in the north to Burma in the south, and from the Ladákh wazárat of Kashmir in the west to the Chinese provinces of Sze-ch'uen and Yünnan in the east. In the first place we have the various Tibetan dialects, spoken all over Tibet and in the neighbouring districts of India and China The Himalayan dialects are spoken in the southern Himalayas, from Lahul in the west to Bhutan in the east East of Bhutan, to the north of the Assam valley, a third small group, the North Assam group, consists of three dialects A fourth group, the Bodo group, comprises a series of dialects from Bhutan in the north to the Tippera state in the south, which at one time extended over most of Assam west of Manipur and the Nāgā hills, and even far into Bengal proper. To the west of the Bodos, and in the neighbourhood of the Nāgā hills is a fifth group, the so-called Nāgā group It comprises dialects of very different kinds Some of them approach Tibetan and the dialect of the North Assam group. Others lead over to the Bodo languages, and others again connect the Nāgā dialects with their Tibeto-Burman neighbours to the south and east To the south of the Nāgā hills, in the long chain of hills extending southwards, is a sixth group, the Kuki-Chin dialects. The old Meitei language of Manipur lies midway between this group and the easternmost branch of the Tibeto-Burman family, the Kachin group, in the tract of country to the east of Assam and to the north of Upper Burma, including the headwaters of the Chindwin and the Irrawaddy. The Kachin and the Kuki-Chin gradually and finally merge into Burmese, the language of the ancient kingdom of Burma.

The dialects spoken in the Himalayas and in Assam can be viewed as a double chain connecting Tibetan with Burmese, the two principal languages of the family. In the first place the Kachin group runs from the easternmost Tibetan dialects in Sze-ch'uen down to the Burmese of Upper Burma. The second chain has a double beginning in the north, one line through the North Assam group, the Nāgā, Bodo and Kuki-Chin groups, another line proceeding from Tibetan through the Himalayan and Bodo groups into Kuki-Chin, finally merging into Burmese.



THE SYMBOLS OF THE TIBETAN ALPHABET



THE SYMBOLS OF THE BURMESE ALPHABET

The Tibeto-Burman languages are closely related to Chinese and Tai, more closely to the former than to the latter. The agreement is apparent in the phonetical system, in vocabulary and in grammar. The principal point in which they differ is the order of words. The Tibeto-Burman family arranges the words of a sentence in the order of subject, object, verb, while the order in Chinese and Tai is subject, verb, object Together all these languages form one great family, now called Sino-Tibetan.

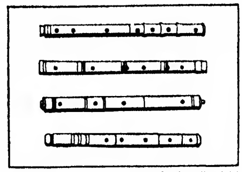
TIBIA, a pipe played by means of a reed mouthpiece, extensively used in classic Rome. The tibia, often mistranslated "flute," was identical with the aulos (*q.v.*) of the Greeks, and it may be regarded as the prototype of our clarinet or oboe (*qq.v*).



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE TIBIA, A REED INSTRUMENT OF ANCIENT ROME

TIBULLUS, ALBIUS (*c* 54–19 B.C.), Latin elegiac poet The information which we possess about him is extremely meagre. Besides the poems themselves—that is to say, the first and second books—we have only a few references in later writers and a short *Life* of doubtful authority. We do not know his praenomen; his gentile name has been questioned; nor is his birthplace ascertained His station was not improbably that of a Roman knight (so the *Life* affirms); and he had inherited a very considerable estate. But, like Virgil, Horace and Propertius, he seems to have lost the greater part of it in 41 amongst the confiscations which Antony and Octavian found expedient to satisfy the rapacity of their victorious soldiery Tibullus's chief friend and patron was M. Valerius Messalla Corvinus, himself an orator and poet as well as a statesman and a commander Messalla, like Maecenas, was the centre of a literary circle in Rome, but the bond between its members was that of literature alone. They stood in no relations to the court; and the name of Augustus is not once to be found in the writings of Tibullus. About 30 B C. Messalla was despatched by Augustus to Gaul to quell a rising in Aquitania and restore order in the country, and Tibullus may have been in his retinue. On a later occasion, probably in 28, he would have accompanied his friend who had been sent on a mission to the East, but he fell sick and had to stay behind in Corcyra Tibullus had no liking for war, and though his life seems to have been divided between Rome and his country estate, his own preferences were wholly for the country life His first love, the subject of book i, is called Delia in the poems, but we learn from Apuleius (*Apol* 10) that her real name was Plania. Delia seems to have been a woman of middle station. It is impossible to give an exact account of the intimacy. The poems which refer to her are arranged in no chronological order. Now she appears as single, now as married, but we do not hear anything either of her marriage or of her husband's death. It is clear, however, that it was the absence of her husband on military service in Cilicia which gave Tibullus the opportunity of making or renewing the acquaintance. It was not dropped when he returned. It was not difficult to deceive the simple soldier; and Delia was an apt pupil in deception—too apt, as Tibullus saw with dismay when he found that he was not the only lover. His entreaties and appeals were of no avail; and after the first book we hear no more of Delia. In the second book the place of Delia is taken by Nemesis, which is also a fictitious name. Nemesis (like the Cynthia of Propertius) was a courtesan of the higher class; and she had other admirers besides Tibullus. He complains bitterly of his bondage, and of her rapacity and hardheartedness. In spite of all, however, she seems to have retained her hold on him until his death. Tibullus died prematurely, probably in 19, and almost immediately after Virgil. His death made a deep impression in Rome, as we

learn from his contemporary Domitius Marsus and from the elegy in which Ovid (*Amores*, iii. 19) has enshrined the memory of his predecessor.

The character of Tibullus is reflected in his poems. Though not an admirable it is certainly an amiable one. He was a man of generous impulses and a gentle unselfish disposition. He was loyal to his friends to the verge of self-sacrifice, as is shown by his leaving Delia to accompany Messalla to Asia, and constant to his mistresses with a constancy but ill deserved. His tenderness towards them is enhanced by a refinement and delicacy which are rare among the ancients. Horace and the rest taunt the cruel fair with the retribution which is coming with the years. If Tibullus refers to such a fate, he does it by way of warning and not in any petty spirit of triumph or revenge. Cruelly though he may have been treated by his love, he does not invoke curses upon her head He goes to her little sister's grave, hung so often with his garlands and wet with his tears, and bemoans his fate to the dumb ashes there. Tibullus has no leanings to an active life. his ideal is a quiet retirement in the country with the loved one at his side He has no ambition and not even the poet's yearning for immortality As Tibullus loved country life, so he clung to its faiths, and in an age of crude materialism and the grossest superstition, he was religious in the old Roman way As a poet he reminds us of Collins and Longfellow His clear, finished and yet unaffected style made him a great favourite with his countrymen and placed him, in the judgment of Quintilian, at the head of their elegiac writers And certainly within his own range he has no Roman rival For natural grace and tenderness, for exquisiteness of feeling and expression, he stands alone He has far fewer faults than Propertius, and in particular he rarely overloads his lines with Alexandrian learning. But, for all that, his range is limited; and in power and compass of imagination, in vigour and originality of conception, in richness and variety of poetical treatment, he is much his rival's inferior. The same differences are perceptible in the way the two poets handle their metre Tibullus is smoother and more musical, but liable to become monotonous, Propertius, with occasional harshness, is more vigorous and varied It may be added that in many of Tibullus's poems a symmetrical composition can be traced, although the symmetry must never be forced into a fixed and inelastic scheme

The third book, which contains 290 verses, is by a much inferior hand The writer calls himself Lygdamus and the fair that he sings of Neaera He was born in the same year as Ovid, but there is nothing Ovidian about his work He has a good many reminiscences and imitations of Tibullus and Propertius; and they are not always happy. The separation of the fourth book from the third has no ancient authority It dates from the revival of letters, and is due to the Italian scholars of the 15th century The fourth book consists of poems of very different quality. The first is a composition in 211 hexameters on the achievements of Messalla, and is very poor. The author was certainly not Tibullus.

The value of the short *Vita Tibulli*, found at the end of the Ambrosian, Vatican and inferior mss, has been much discussed There is little in it that we could not at once infer from Tibullus himself and from what Horace says about Albius, though it is possible that its compiler may have taken some of his statements from Suetonius's book *De poetis*. It is another moot question of some importance whether our poet should be identified with the Albius of Horace (*Od* i. 33; *Epist.* i. 4), as is done by the Horatian commentator Porphyrio (A D. 200–250) in his *Scholia* Porphyrio's view has been examined by Postgate (*Selections from Tibullus*, appendix A). If it is rejected the authority of the *Life* is considerably impaired. Delia's name (from δῆλος) is a translation of Plania. As regards her station, it should be noticed that she was not entitled to wear the *stola*, the dress of Roman matrons (i. 6, 68). Her husband is mentioned as absent (i. 2, 67 *seq*) Lygdamus is probably the real name of the author of the first six elegies in book iii., but little further is known about him His elegies and the other poems in the third book ("third" and "fourth" books) appear to have been known to Ovid. There are agreements much too close to be accidental. Most scholars since Lachmann have condemned the "Panegyric on Messalla." It is an inflated and at the same time tasteless declamation, entirely devoid of poetical merit. The language is often absurdly exaggerated, *e g.*, 190 *seq* The author himself seems to be conscious of his own deficiencies (1 *seq*, 177 *seq.*). Like so many of his contemporaries, he had been reduced to poverty by the loss of his estates (181 *seq.*). Sulpicia was the daughter of Servius Sulpicius (iii. 16; iv 10, 4), and she seems to have been under the tutelage of Messalla, her uncle by marriage (Haupt, *Opuscula*, iii. 502)

MANUSCRIPTS—The two best mss of Tibullus are the Ambrosianus (A), of date about 1374, and the Vaticanus (V), of the 15th century. Besides these we have a number of extracts from Tibullus in *Florilegium Parisinum*, an anthology from various Latin writers which probably goes back to the 11th century, and the *Excerpta frisingensia*, preserved in an 11th-century ms now at Munich, unfortunately very few in number Also excerpts from the lost *Fragmentum cuiacianum*, made by Scaliger, and now in the library at Leyden It only contained the part from iii. 4, 65 to the end. The *Codex cuiacianus*, a late ms containing Catullus, Tibullus and Propertius, is still extant

BIBLIOGRAPHY.—Tibullus was first printed with Catullus, Propertius, and the *Silvae* of Statius by Vindelinus de Spira (Venice, 1472), and separately by Florentius de Argentina, probably in the same year. Amongst other editions we may mention those by Scaliger (with Catullus and Propertius, 1577, etc), Broukhusius (1708), Vulpius (1749), Heyne (1817, 4th ed by Wunderlich, with supplement by Dissen, 1819), Huschke (1819), Lachmann (1829), Dissen (1835). Among more recent texts Bahrens (1878, the first of the modern critical editions), L Muller (1880, with a useful introduction), Hiller (1885, with index verborum and in the *Corpus Poetarum Latinorum*, 1905), Postgate (1905). Of the commentaries Heyne's, Huschke's and Dissen's are still of value, *see* also Nemethy's (with Latin notes 1905–1906). The greater part of the poems are included in Postgate's *Selections* (with English notes, 1903). For further information *see* the accounts in Teuffel's *History of Roman Literature* (translated by Warr), Schanz's *Geschichte der romischen Literatur*, Marx's article *s v* "Albius," in Pauly-Wissowa's *Realencyclopadie*; A Cartault's *A propos du corpus Tibullianum* (1906); *see* also his *Tibulle et les auteurs du Corpus Tibullianum* (1909), and *Le Distique élégaique chez Tibulle* (1911); R. Burger, *Beitrage zur Elegantia Tibulls* (1911); and M Ponchont (ed), *Tibulle et les auteurs du Corpus Tibullianum* (1924) Cranstoun's translation (1872) is the only complete version of merit, but it is far inferior to those in C. A Elton's *Specimens of the Classical Poets* (1814). (J. P. P; X)

TIBUR (mod. Tivoli, *q v*), an ancient town of Latium, 18 m. E N E of Rome by the Via Tiburtina (*See* TIBURTINA, VIA.) It is finely situated at the point where the Anio forms its celebrated falls, it is protected on the east, north and north-west by the river and it commands the entrance to its upper course, with an extensive view over the Campagna below. The modern town is in part built upon the extensive terraces of the temple (itself a comparatively small building) of Hercules Victor, the chief deity of Tibur, of which some remains exist. Below it, on the cliffs above the Anio, is a large building round a colonnaded courtyard built over the Via Tiburtina (which passes under it in an arched passage), the meeting place of the Herculanei Augustales

Remains of two small temples of the late Republic—one circular, with Corinthian columns, the other rectangular with Ionic columns—stand at the north-east extremity of the town, above the waterfalls, traditionally, but wrongly, attributed to Vesta and the Sibyl of Tibur. The so-called Tempio della Tosse, an octagonal structure, is probably a tomb of the 4th century A D

Tibur was a favourite place of resort in Roman times, and both Augustus and Maecenas had villas here, and Horace also A house shown as being his in the time of Suetonius is identified with a villa of the Augustan period, over which is built the monastery of S. Antonio. In his poems he frequently mentions Tibur with enthusiasm Catullus and Statius, too, have rendered it famous. The abundance of water from aqueducts and springs and the falls of the Anio were among its chief attractions. The remains of villas in the district are numerous and important (*See* T Ashby in *Papers of the British School at Rome*, iii) The largest is that of Hadrian, situated in the low ground about 2 m. to the south-west of Tibur, and occupying an area of some 160 acres. A number of statues have been found in the villa, and costly foreign marbles and fine mosaic pavements, some of the last being preserved *in situ*. Excavations have gone on since the 16th century, and are now carried on by the Italian government. *See* H Winnefeld *Die Villa des Hadrian* (Berlin 1895); *Jahrbuch des k. d.*

arch. Instituts, Erganzungsheft iii.: R. Lanciani, *La villa Hadriana* (Rome 1906)

The ancient Tibur, though on the edge of the Sabine mountains, was a member of the Latin League There are remains of ancient roads and outlying forts in its territory dating from the period of its independence. It allied itself with the Gauls in 361 B.C., and in the war which followed the towns of Empulum and Saxula were destroyed and triumphs over Tibur were celebrated in 360 and 354 B C, and again in 338, when its forces were defeated, with those of Praeneste It, however, became an ally of Rome Syphax, king of Numidia, died in the territory of Tibur as a captive in 201 B.C., and in A.D 273 Zenobia, queen of Palmyra, was assigned a residence here by Aurelian Its prosperity during the imperial period was mainly due to the favour in which it stood as a summer resort During the siege of Rome by Narses, Belisarius occupied Tibur, it was afterwards treacherously surrendered to Totila, whose troops plundered it, but who rebuilt it in A D. 547 (T. A.)

TIBURTINA, VIA, an ancient road of Italy, leading E N E from Rome to Tibur (18 m). Though it afterwards became an important thoroughfare, the first portion of it always retained its original name (*See* VALERIA, VIA)

TICHBORNE CLAIMANT, THE. Roger Charles Tichborne (1829–1854), whose family name became a household word on account of an attempt made by an impostor in 1868 to personate him and obtain his heritage, was born at Paris on Jan 5, 1829, the eldest son of James Francis Doughty-Tichborne (who subsequently became 10th baronet and died in 1862) by Henriette Felicité, natural daughter of Henry Seymour of Knoyle, in Wiltshire He sailed in March 1853 from Havre for Valparaiso, whence he crossed the Andes, reaching Rio de Janeiro in 1854 In April of that year he sailed from Rio in the "Bella" and was lost at sea, the vessel foundering with all hands His insurance was paid and his will proved in July 1855 The baronetcy and estates passed in 1862 to Roger's younger brother, Sir Alfred Joseph Doughty-Tichborne, who died in 1866 The only person unconvinced of Roger's death was his mother the dowager Lady Tichborne, from whom every tramp-sailor found a welcome at Tichborne Park She advertised largely and injudiciously for the wanderer, and in November 1865 she learnt, through an agency in Sydney, that a man "answering to the description of her son" had been found in the guise of a small butcher at Wagga Wagga, in Queensland. Lady Tichborne "acknowledged" him as her son when he reached Paris in 1867. Other members of the family, however, obtained evidence that the claimant was identical with Arthur Orton (1834–1898), the son of a Wapping butcher, who had deserted a sailing vessel at Valparaiso in 1850, and had received much kindness at Melipilla in Chile from a family named Castro, whose name he had subsequently elected to bear during his sojourn in Australia An ejectment action against the trustees of the Tichborne estates (to which the heir was the 12th baronet, Sir Henry Alfred Joseph Doughty-Tichborne, then two years old) finally came before the court of common pleas on May 11, 1871 During a trial that lasted over one hundred days over a hundred persons swore to the claimant's identity, the majority of them—and they were drawn from every class—being evidently sincere in their belief in his cause But the evidence of the Tichbornes finally convinced the jury, who declared that they wanted no further evidence Orton was arrested on a charge of perjury and was brought to trial at bar before Chief Justice Cockburn in 1873. The indiscretion of his counsel, Edward Kenealy, the testimony of his former sweetheart, and Kenealy's refusal to put the Orton sisters in the box, proved conclusive to the jury, who, on the 188th day of the trial, found that the claimant was Arthur Orton. Found guilty of perjury on two counts, he was sentenced on Feb. 28, 1874 to fourteen years' penal servitude Orton died in obscure lodgings in Marylebone on April 2, 1898 (T. S)

See J. Brown, *The Tichborne Case compared with previous impostures* (1874).

TICINO, a wedge-shaped Swiss canton, driven into Italy. Its northern boundary runs along the Lepontine-Adula alps, and its southern tip reaches beyond Lago di Lugano almost to Como. Historically, it represents early Swiss conquests from the duchy of Milan (*see* SWITZERLAND, *History*) loosely amalgamated to form one of the six cantons admitted to the Confederation in 1803. It is inhabited by Italian-speaking Catholics (*see* below). Its dominant physical features are the three river systems occupying steep-sided valleys which extend from a mountain frontier and drain southwards to Lago Maggiore. The most important system is the river Ticino, which rises in the canton south-west of St. Gotthard, flows towards that mass through the Val Bedretto, and then swings round at Airolo to a south-east course through Valle Leventina; near Biasca it receives the left-bank Brenno from the Val Blenio; the combined stream flows through the wide, low valley—the Riviera—until slightly above Bellinzona, where it receives another large left-bank affluent which has drained the south-east slopes of the Adula group and reaches the Ticino via the Valle Mesolcina; the main stream curves again below the junction and enters the lake from the east. The Ticino receives no important right-bank tributaries, and the western part of the canton is drained largely by the Maggia and by its numerous right-bank tributaries, which receive torrent water from the western frontier. Between the Ticino and the Maggia, is the Valle Verzasca, which is practically a single stream system; the separate mouths of the three rivers lie close to one another at the head of the lake. The remainder of the canton lies south-south-east of this and consists of a triangular fragment of broken hill country, with a complicated drainage reaching the irregularly shaped Lago di Lugano

Its total area is 1,085 sq m, of which 74% are reckoned as "productive" (forests covering 277 9 sq m, and vineyards 7·1 sq m), while of the remainder 28 6 sq m consists of lakes, chiefly parts of Maggiore and Lugano; 13 sq m are occupied by glaciers The canton is fifth in point of size, but only the much larger Valais and Vaud exceed its vine-growing area The highest points are the Basódino (10,749ft), near the western border, south-east of the source of the Ticino, and the Rheinwaldhorn (11,175ft.) in the Adula alps The amount of lowland is small, and occurs only in the lower river valleys and near the lakes The lowest commune (669ft) is Vira (Locarno) on Lago Maggiore

The main St. Gotthard railway traverses the canton for about 75 m. from Airolo, at the southern mouth of the tunnel, *via* Valle Leventina, Bellinzona, Lugano to beyond Mendrisio. Locarno is connected with this line, another follows the eastern shore of Lago Maggiore, and light railways ascend Valle Maggia to Bignasco, Valle Blenio to Acquarossa, and Valle Mesolcina to Mesocco; the latter two are electric railways. Mountain railways for the ascent of Monte S Salvatore (3,002ft) from Lugano, and of Monte Generoso (5,581ft) from Capolago, have also been constructed in the extreme south of the canton

In 1920 the total population was 152,256, of whom 142,044 were Italian-speaking, 8,461 German-speaking and 1,034 French-speaking. The highest commune, Bosco-Vallem, near the western border and reached by the V. di Campo, had many German-speaking inhabitants, the result of an early movement eastward from Valais. There were in all 140,536 Catholics, 6,078 Protestants and 192 Jews.

In 1888 the diocese of Lugano (since joined to Basle) was created to replace the former purely Italian control over the canton by the dioceses of Milan and Como Bellinzona (pop. 11,800) has been the permanent political capital since 1881; formerly Lugano (13,950) and Locarno (5,050) alternated with it at six-year intervals. Mendrisio (3,600) is the only other large settlement.

The canton has 261 communes and eight administrative districts; its Constitution dates back to 1830, but the later political disturbances which characterize the canton, have caused, and still cause, considerable modifications. The legislature (*Gran consiglio*) is now composed of 65 members elected (since 1892) in the proportion of one to every 1,500 of the Swiss inhabitants. The executive (*Consiglio di stato*) of five members, is elected directly by the people. Both bodies hold office for four years Any 5,000 electors have the right (facultative referendum) of claiming a

popular vote as to bills passed by the legislature, while the same number of electors have the right of "initiative" in legislative matters, though 7,000 signatures are required in case of a proposal to revise the cantonal Constitution.

History.—The canton is made up of all the permanent conquests (with one or two trifling exceptions) made by different members of the Swiss Confederation south of the main chain of the Alps. From an historical point of view Italian Switzerland falls into three groups. (1) the Val Leventina conquered by Uri in 1440 (previously held from 1403 to 1422), (2) Bellinzona (previously held from 1419 to 1422); the Riviera and the Val Blenio, all won in 1500 from the duke of Milan by men from Uri, Schwyz and Nidwalden, and confirmed by Louis XII. of France in 1503; (3) Locarno, Val Maggia, Lugano and Mendrisio, seized in 1512 by the Confederates when fighting for the Holy League against France, ruled by the 12 members then in the league, and confirmed by Francis I in the treaty of 1516 These districts were governed by bailiffs holding office two years and purchasing it from the members of the League; each member of group 3 sent annually an envoy, who conjointly constituted the supreme appeal in all matters This Government was very harsh and is one of the darkest pages in Swiss history Yet only one open revolt is recorded—that of the Val Leventina against Uri in 1755. In 1803 all these districts were formed into one canton—Ticino—which became a full member of the Swiss Confederation. Since 1830 the local history of the canton was disturbed by friction between the Radical and Ultramontane parties

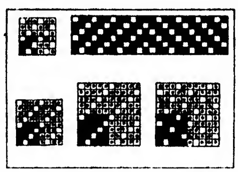
TICINO (Ger *Tessin*, anc *Ticinus*), a river of Switzerland and north Italy, which gives its name to the Swiss canton of Ticino (*q v*), and gave it in classical times to the town of Ticinum (Pavia). It rises at the foot of the Gries pass to the west of Airolo; from Airolo to the Lago Maggiore its valley bears the name of Val Leventina, and is followed as far as Bellinzona by the St Gotthard road and railway It flows through Lago Maggiore, leaving it at its south end at Sesto Calende, and thence flows S S.E. into the Po, which it joins a little way south of Pavia

TICINUM, an ancient city of Gallia Transpadana (mod. *Pavia, q v*), founded on the banks of the river of the same name (mod. *Ticino*) a little way above its confluence with the Padus (Po) Its importance in Roman times was due to the extension of the Via Aemilia from Ariminum to the Padus (187 B C.), which it crossed at Placentia and there forked, one branch going to Mediolanum and the other to Ticinum, and thence to Laumellum whence one branch went to Vercellae (and thence to Eporedia and Augusta Praetoria) and the other to Valentia (and thence to Augusta Taurinorum or to Pollentia) At Ticinum a triumphal arch was erected in honour of Augustus and his family; in the 4th century A D. there was a manufacture of bows there. It was pillaged by Attila in A D 452 and by Odoacer in 476, but rose to importance as a military centre in the Gothic period. At Dertona and here the grain stores of Liguria were placed, and Theodoric constructed a palace, baths and amphitheatre and new town walls. From this point, navigation on the Padus began. Narses recovered it for the Eastern Empire, but after a long siege, surrendered it to the Lombards in 572. The regular ground plan of the central portion of the modern town, a square of some 1,150 yd., betrays its Roman origin

TICKELL, THOMAS (1686–1740), English poet and man of letters, the son of a clergyman, was born at Bridekirk near Carlisle in 1686. In 1715 Tickell brought out a translation of the first book of the *Iliad* contemporaneously with Pope's version. Addison's reported description of Tickell's version as the "best that ever was in any language" roused the anger of Pope, who assumed that Addison himself was the author, or had at any rate the principal share in the work Addison gave Tickell instructions to collect his works, which were printed in 1721 under Tickell's editorship. In 1724 Tickell was appointed secretary to the lords justices of Ireland—a post which he retained until his death, which took place at Bath on April 23, 1740.

TICKER, a small printing machine operated by telegraph (*q.v.*), by means of which information is given from an exchange or trading centre as to the prices of securities and commodities Besides the "stock" ticker there are similar machines which furnish quotations upon various commodities such as grain, coffee and sugar Sometimes important news is sent over the machine (*See* TELEGRAPH) A man in the exchange sits at a keyboard, carrying upon it all the letters and forms used in quotations. As he reads the quotations he perforates a moving tape by striking the keys just as in operating a typewriter This tape passes through a transmitter which operates a large number of line relays and sends the signals to the local and distant points The instrument has been in use many years and was one of the first devices to receive the attention of Thomas A Edison

TICKET-OF-LEAVE, in the English penal system, a document or "pass" granted under the Penal Servitude Acts, and handed to a convict who has completed the second stage of his sentence and is about to enter the third and last, that of conditional liberation or semi-freedom, in which he goes at large to earn his own livelihood as a more or less independent member of the community The "ticket" or "licence" is the outward sign of "remission" gained by industry and good conduct in prison (*q v*), and it may be forfeited for disobedience or neglect of certain conditions endorsed upon the licence The term is not used in the U S. where it is replaced by the parole system



VARIOUS TYPES OF TICKING
Top left, ordinary three-leaf twill; top right, "Arrow head" twill; left bottom and centre, four- and five-thread straight twills; right bottom, five-thread steen twill

TICKING. A strong linen, cotton or union fabric usually woven in stripes of colour, blue and red with white being the most common The name is derived from a word "tick," common in various forms to many languages, signifying a case or sheath Its original use was to enclose feathers, flocks or the like for beddings, but its use has been extended to include the covering for mattresses, and for awnings and tents In some qualities it is also used as a foundation for embroidery

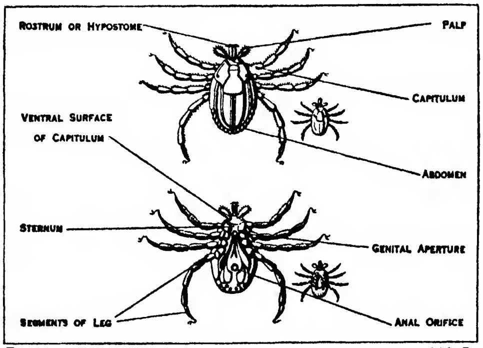
White, grey or brownish warp threads are usually flax, while the coloured threads are often cotton. The weft is flax or tow The warps of many of the cheaper kinds are made entirely of cotton, and jute is used for weft in the cheapest grades A feather tick should be made of fine flax yarns set closely, and there should also be a large number of weft threads per inch

TICKLE-GRASS (PANICUM CAPILLARE)
On the left is shown the free grain, and right, the grain is enclosed in the hardened fruiting scale

TICKLE-GRASS (*Agrostis hyemalis*), a North American grass, called also hair-grass, found widely throughout the continent and in various districts occurring in weed-like abundance It is a delicate plant of open grounds, bearing small flowering spikelets at the ends of the hair-like branches of a very diffuse panicle At maturity the fruiting panicle breaks away from the plant and is blown about as a tumble-weed (*q.v.*).

TICKS, the name for Acari, of the order Arachnida (*q v*), of the families Ixodidae and Argasidae They have on the head

a median probe, armed with recurved teeth, which projects forwards. Ticks are of relatively large size, female specimens of some species measuring half an inch or more in length when distended after being gorged with blood. The mouth parts consist of two small retractile mandibles, a pair of short palpi and the toothed probe or hypostome By means of the hypostome ticks pierce the skin and adhere to the host whose blood they suck. In the Argasidae the palpi are simple; there is no sucker beneath the claws and there is only a slight difference between the sexes. In the Ixodidae the second and third segments of the palpi form a sheath for the hypostome; there is a sucker beneath the claws and the males have the dorsal integument continuously chitinized, whereas in the females only its anterior portion bears a chitinous plate.



THE TICK (HYALOMMA AEGYPTUM), SEEN FROM THE DORSAL (ABOVE) AND VENTRAL (BELOW) SIDES, SHOWING THE PIERCING MOUTH PARTS (ROSTRUM) AND HOOKED LIMBS BY WHICH IT GRASPS ITS HOST

Both families contain pathogenic species *Ornithodoros moubata,* belonging to the Argasidae, is widely distributed in tropical Africa from Uganda in the north to the Transvaal in the south. It is the carrier of the Spirochaete of relapsing fever in man An allied species, *O. turicata,* occurs in Mexico and Texas, where it is a pest to mankind and to poultry. *Argas miniatus* is the carrier of the Spirochaete causing spirillosis in fowls in Rio de Janeiro and New South Wales Amongst the Ixodidae several forms are injurious to man and domestic animals. *Dermacentor venustus* is the carrier of the human disease known as Rocky Mountain Spotted Fever. *Dermacentor reticulatus,* widely distributed in Europe, Asia and America, infects dogs with the Haematozoon causing "biliary fever." The same disease results in South Africa from the bite of *Haemaphysalis leachi Amblyomma hebraeum,* the bont tick of the Cape Colonists, infects sheep with the Sporozoon causing "heart-water" sickness, and in Europe sheep are inoculated with the same disease by *Rhipicephalus bursa.* The "coast fever" in cattle in South Africa is conveyed by *Rhipicephalus appendiculatus* and *R. simus. Margaropus annulatus* is the carrier of the germ causing the cattle-disease known as "Texas" or "red-water" fever in America, South Africa and Australia. With one or two exceptions, no species of tick is confined to a particular host, and reptiles are infested as well as mammals.

TICONDEROGA, a village in the township of Ticonderoga, Essex county, New York, U.S A., on the outlet of Lake George, 100 m. by rail N by E. of Albany. Pop (1925), 3,858 Ticonderoga is served by the Delaware and Hudson and the Rutland railways. The water from Lake George falls here about 30 ft, providing water-power, and among the manufactures are paper pulp, paper-making machinery and lumber. Commanding a portage on the line of water communication between Canada and the English colonies, Ticonderoga was a place of considerable strategic importance during the Seven Years' War. On an eminence overlooking the present village and Lake Champlain the French began building a fort of earth and timber in 1755 and called it Fort Carillon; later it was named Fort Ticonderoga. Sir William Johnson led an expedition in the same year against this fort and Crown Point; though he failed to capture the forts he defeated Baron Ludwig August Diesku in the battle of Lake George and erected at the head of the lake Fort William Henry, which was captured by the marquis de Montcalm in 1757. On July 8, 1758, less than 4,000 Frenchmen were confronted at Fort Carillon by about 6,000 British regulars and 10,000 provincials under Lieut-General James Abercrombie and Brigadier-General George A Howe, but Howe, the controlling spirit of the British force, had been killed on July 6, and Abercrombie retreated, after an ineffective attack which cost him nearly 2,000 men killed or wounded. In 1758, however, when Montcalm had gone to Quebec to oppose Wolfe and a force of only 400 men was left at Ticonderoga, Lord Amherst with 11,000 men invested it, and on July 26 the garrison blew up and abandoned the fortifications. At the beginning of the Revolutionary War, on May 10, 1775, a small expedition under Ethan Allen, a backwoods strategist untrammelled by military pedantry, captured the fort by ruse instead of costly assault. When the American expedition against Canada was driven back from Quebec they garrisoned Ticonderoga so strongly that the British commander, Carleton, shrank from attacking it In 1777, however, Burgoyne's counter invasion from Canada arrived before the fort and occupied the precipitous Sugar Loaf Hill which commanded the fort The garrison, already reduced in numbers and supplies, felt compelled to evacuate it and on July 6 the British occupied it. Burgoyne, pressing onwards to the Hudson, was driven to surrender at Saratoga in October; Ticonderoga was abandoned by the British immediately after this disaster, but was reoccupied by them in 1780 After the close of the war it was allowed to fall into ruins. In 1909, on the occasion of the tercentenary celebration of the discovery of Lake Champlain, the restoration of the fort was begun under the direction of the owner of the site. The settlement of this region was begun soon after the close of the Seven Years' War, and the township of Ticonderoga was set apart from the township of Crown Point in 1804 The village of Ticonderoga was incorporated in 1889. The name "Ticonderoga" is a corruption of an Indian word said to mean "sounding waters"

TICUNAN, a small group of tribes of South American Indians, constituting an independent linguistic stock The Ticunas and their related tribes lived in western Brazil, on the lower Yavary river and on the main Amazon for some distance below the junction of the two streams.

TIDAL POWER. The idea of utilizing the rise and fall of the tides for power purposes has long attracted the attention of inventors, and many ingenious schemes have been suggested. So far, however, the only practicable method is based on the use of one or more tidal basins, separated from the sea by dams or barrages, and of hydraulic turbines through which the water is passed on its way between basin and sea or between one basin and another.

Types of Schemes.—Briefly outlined the more promising of the schemes of tidal power development are as follows:—

(*a*) A single tidal basin is used, divided from the sea by a dam in which are placed the turbines The basin is filled through sluices during the rising tide. At high tide these are closed. When the tide has fallen through about one-half its range, the turbine gates are opened and the turbines operate on a more or less constant head until low tide or slightly after. If A be the surface area of the basin in square feet; if H ft. be the tidal range; if a constant working head of h ft. be adopted; and if the turbines operate until low tide; the volume of water used during the falling tide will be $A\ (H-h)$ cu ft, and the energy available in the water will be

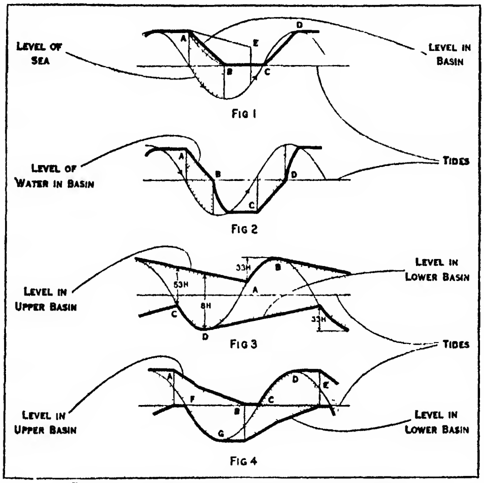
$$64A\ (H-h)\times h,\ \text{ft lb. per tide.}$$

This expression is a maximum when $h=H\div 2$, that is, when the working head is one-half the tidal range, and then equals $16\ AH^2$ foot-pounds.

If A is in square miles, and if the efficiency of the turbines is 75%, the output in h-p.-hours per tide is given by

$$\frac{0\cdot75\times64(5280)^2AH^2}{4\times33000\times60}=169AH^2.$$

The cycle of operations is shown in fig. 1 where AB denotes the working period and CD the period of replenishment of the basin. The sine curve represents the level of the sea outside the basin. Owing to the great variation in the rate of efflux of the water, in this constant-head method of operation, the power output varies very largely during the falling tide. This variation may be reduced considerably by allowing the turbines to operate on a more or less constant fall of level in the basin as shown by the straight full line AB. By this method of operation the necessary turbine capacity for a given output may be greatly reduced By extending the working period beyond low tide, as indicated by the light line AE, a greater amount of energy may be developed per tide and the idle period is diminished, but at the expense of an appreciably greater variation in head The most efficient combination of working period and of working heads can only be determined by detailed examination of the particular site, and with a knowledge of the exact form of the tidal curve.



PLAN OF SCHEMES FOR TIDAL POWER DEVELOPMENT

Fig. 1.—Single tidal basin, divided from sea by a dam containing turbines operating only during ebb tide. Fig 2.—Single tidal basin, with turbines operating on rising and falling tides. Fig. 3 —Two tidal basins with turbines in dividing walls. Fig. 4.—Two tidal basins with turbines installed in walls dividing sea from each basin The heavy lines show the water level in the basin at any instant, and the light lines show the sea level at the same instant. The shaded areas represent the working heads when the turbines operate

(*b*) A single tidal basin is used, with the turbines operating on both rising and falling tides The cycle of operations is indicated in fig 2. The working period per complete tide now extends from A to B and from C to D. Slightly before low water, at B, the basin is emptied through sluice gates, and at D, a little before high water, the basin is filled through the sluice gates. With a working head equal to one-half the tidal range, the period of operation is approximately 60% greater than in system (*a*) with operation down to low tide, and the work done is some 60% greater

(*c*) Two basins of approximately equal areas are used, with turbines in the dividing wall. Each basin communicates with the sea through suitable sluice gates. In one of these basins called the upper, the water level is never allowed to fall below one-third of the tidal range, while in the lower basin the level is not allowed to rise above one-third of the tidal range. The working head then varies from 0·53 H to 0·80 H, with a mean of approximately 0·66 H, and operation is continuous as indicated in fig. 3 which shows the cycle of operations. Between A and B, the upper basin is filled from the sea through appropriate sluice gates, and the lower basin discharges into the sea from C to D. For a given total basin area and a given tidal range the output is only about one-half that obtained in system (*a*) and one-third that obtained in system (*b*), so that except where the physical configuration of the site is particularly favourable the cost per h.p. is likely to prove very high.

(*d*) Two tidal basins of approximately equal areas are used. Turbines are installed in the walls dividing the sea from each basin. Fig. 4 shows the cycle of operations From A to B the upper basin discharges through its turbines into the sea. From B to E the sea enters the lower basin through its turbines. The upper basin is filled from the sea through its sluice gates between C and D, and the lower basin is emptied through its sluice gates from F to G. The head varies from 0·25 H to 0·62 H, and the output is some 25% greater than in system (*c*) but the number of turbines required is much greater.

It is possible to arrange in each of these systems that the head shall be maintained constant during any one working period, but since this means that the working head is then limited to the minimum obtaining during that period, a loss of energy is involved, with a great additional cost of construction and complication in manipulation and with little compensating advantage. For any scheme of development involving the use of a tidal estuary of such types as are found in the Severn or Dee, the cost of any of the multiple basin systems would appear to put them definitely out of court A scheme involving operation only on a falling tide has the disadvantage that the output is only about 60% of the output theoretically possible with double-way operation. On the other hand the output per unit of turbine capacity is sensibly the same, while it enables a much more efficient type of turbine setting to be used, and halves the number of sluice gates.

The Severn Scheme.—Up to 1928 no tidal scheme of any magnitude had been constructed The possibilities of such an installation on the estuary of the Severn are, however, now under consideration by a committee appointed by the British Government This would consist of a single tidal basin of about 25sq m. in area formed by a barrage probably in the neighbourhood of Sudbury, along with a storage reservoir some 500ft above sea-level and about 5m away above the Wye valley. It is estimated that the scheme would be capable of developing some 500,000h p. over a 10-hour working day throughout the year.

Fundy Bay Scheme.—Two schemes, each of the two-basin type, have been suggested for utilizing the tides in the Bay of Fundy (*q v*). From one of these, at Passamaquoddy Bay, where the average spring tidal range is 23·2 ft , it is estimated that from 500,000 to 700,000 h p can be generated The other, which is a smaller but relatively less costly scheme, is at Hopewell at the head of Shepody Bay, and utilizes the estuaries of the Petitcodiac and Memramcook rivers as the two tidal basins. Here the spring tidal range is 45 5 ft and the available power about 200,000 h p Both schemes have been before the New Brunswick Government.

Aber-Vrach Scheme.—A combined tidal and river-power scheme to which the French Government is giving financial assistance is projected at Aber-Vrach on the coast of Brittany For the tidal station a barrage 490ft. long is to be constructed in the estuary. Four turbines connected to synchronous generators are to be installed, each capable of developing 1,200h p , under the maximum head available at spring tides The turbines are to operate both on the ebb and flow tides This station will work in conjunction with an auxiliary water-power station some 4m. away on the river Diouris. The river is to be dammed at this point, forming a fresh water reservoir from which turbines having a maximum capacity of 2,700h p. are to be supplied. Electrically driven centrifugal pumps of a capacity of 3,200h p will also be installed

TIDES. 1. The word "tide" refers to those alternating relative motions of the matter of the planet, satellite or star, which are due to the gravitational actions of external bodies Two terrestrial examples besides the tides of our oceans and seas are

earth-tides and atmospheric tides. They consist in the alternating slight change of shape due to the gravitational action of the moon and sun. There is, however, a still wider use of the word which has some convenience. It is based on descriptive and kinematical, instead of on causal and astronomical ideas, and takes for criterion that the motions in question shall have certain features in common with ocean-tides. This extension includes those "long" waves of the sea which are sometimes caused by earthquakes, the effects on the sea of variable atmospheric pressure, as well as the oscillations of the water of lakes known as "seiches."

Ordinary Tides.—2 At most seaside places the water reaches its highest level approximately twice a day, the average interval between two successive high waters being 12 hr. 25 min, but the interval varies considerably during the course of a week, while at certain places in the China sea the interval is often over 24 hours. At places on the shores of the oceans the time taken by the tide in rising is about equal to the time taken in falling on the same day, but in estuaries the tide usually rises quicker than it falls At certain places, such as Southampton, England, the high waters are often doubled, *i.e.*, the water reaches a maximum height, falls a little and then rises to a maximum again. At other places, the low waters are often doubled As we go along any stretch of coast the time of high water changes progressively, while as we go up an estuary from the sea the time of high water always becomes progressively later.

At most places, on the average, a high water is about as much above the mean level of the sea as the succeeding low water is below it The difference in level between successive high and low waters is called the *range* of tide At most places it reaches a maximum once a fortnight, and a minimum midway between two successive maxima At the head of the Bay of Fundy the range of tide reaches 50 ft, while at certain islands of the Pacific and over most of the Mediterranean the range never exceeds 2 ft. At many places outside the Atlantic the heights of two successive high or low waters are markedly different, a phenomenon known as *diurnal inequality.*

At a place in a strait or narrow sea the tidal current usually flows for about 6 hr 12 min. in each direction At the reversal of the current we have the state of rest usually called *slack water.* At a place in the open sea the direction of the current often takes all points of the compass, making the complete revolution in the tidal period. During this period there are usually two times of maximum, and two intermediate times of minimum current, separated by about half the tidal period In general there is no fixed relation between the time of high water and the time of maximum current; but if the current flows directly in and out of a bay it will reach its inward maximum about a quarter period before high water at the head of the bay, so that slack water is simultaneous with high water On the other hand in an estuary the upstream maximum will occur at a much shorter interval before high water, so that the current continues to flow upstream for some time after high water and to run down stream after low water. When the current is directed towards land or up an estuary, it is called the *flood* current; when it runs away from the land it is called the *ebb.*

The speeds of tidal currents vary greatly from place to place; *e.g.,* in the Mersey at Liverpool the maximum current reaches 7 knots, while in the North sea it rarely exceeds 1 knot. At some distance up certain rivers the rising water spreads over the flat sands in a roaring surf and travels up the river almost like a wall of water. This phenomenon is called a *bore.* Near a headland separating two bays there is sometimes a very swift current, termed a *race.*

HISTORY OF THE STUDY OF TIDES

3. The theories of tides advanced by the early Chinese, Arabic and Icelandic authors, are fantastic The Greeks and Romans lived on the shores of an almost tideless sea and therefore seldom referred to tides. Nevertheless Strabo quoted from Posidonius a clear account of the tides on the Atlantic coast of Spain, and connected them correctly with the motion of the moon He also gave the laws of the tide and diurnal inequality in the Indian ocean as observed by Seleucus the Babylonian. Kepler (*q.v.*) recognized the tendency of the water of the ocean to move towards the sun and moon, but produced a theory which appeared to reintroduce the occult qualities of the ancient philosophers. Galileo (*q.v.*) referred the phenomenon to the rotation and orbital motions of the earth, and he considered that it afforded a principal proof of the Copernican system.

Foundation of Modern Theory.—It was Newton (*q v.*) who, in his *Principia* of 1687, laid the foundation of the theory of the tides when he brought his generalization of universal gravitation to bear on the subject He used an artifice of imaginary wells of water reaching to the centre of the earth where the pressure-intensities would be equal He accounted for many of the general properties of the tides, such as the phenomenon of springs and neaps, priming and lagging, diurnal and elliptic inequalities The only important factor which he did not mention is the dynamical effect of the earth's rotation. He attempted to calculate the magnitude of the lunar equilibrium-tide from data provided by the actual tides

In 1738 the Academy of Sciences of Paris offered as a subject for a prize the theory of the tides The authors of four essays received prizes, viz, Bernoulli, L Euler, C Maclaurin (*qq v*) and A Cavalleri The first three adopted not only the theory of gravitation but also Newton's method of the superposition of two ellipsoids. Laplace (*q v*) gave an account and critique of the essays of Bernoulli and Euler in his *Mécanique Céleste* In 1746 J. le R D'Alembert wrote a paper on atmospheric tides

The theory of the tidal movements of an ocean was almost untouched when, in 1774, Laplace first undertook the subject He formulated the equation of continuity and the dynamical equations (*See* his *Mécanique Céleste*) He also established the principle of forced oscillations, often known by his name, viz, "The state of oscillation of a system of bodies in which the primitive conditions of movement have disappeared through friction is co-periodic with the forces acting on the system" The tidal application of this is the foundation of the harmonic method

The connection between the tides and the movements of the moon and sun is so obvious that tidal predictions founded on empirical methods were regularly made and published long before mathematicians had devoted their attention to them. The best example of this kind of tide-table was afforded by Holden's tables for Liverpool The use of automatic tide-gauges appears to have been begun about 1830, two of the earliest machines being those of H. R. Palmer (*Phil Trans*, 1831) and J. G. Bunt (*Phil. Trans*, 1838).

Co-ordination of Observations and Harmonic Analysis.—4 The work of Lubbock and Whewell is chiefly remarkable for the co-ordination and analysis of data at various ports, and the construction of tide-tables. In 1838 Whewell produced his "Essay towards a first approximation to a map of co-tidal lines." (*Phil. Trans.*) He was led to perceive the existence of the amphidromic point (§ 15) in the Flemish bight, and this led to the observational verification by W. Hewett (*Brit. Ass. Report,* 1841) of the small range near the point. Airy, in his *Tides and Waves* of 1842, contributed an important review of the whole tidal theory and studied profoundly the theory of tidal motions in canals. The results given in §§ 17, 18, 22 for canals and gulfs of uniform section are only a few of his many achievements in this connection. In 1847 and 1857 F. W. Beechy published (*Phil. Trans.*) the results of a survey of tidal currents over the Irish sea, the English channel and North sea.

About 1863 W. Thomson (afterwards Lord Kelvin, *q.v.*) became interested in the problems presented by earth-tides. In 1866 he took up the analysis of ordinary tidal observations and introduced the methods of harmonic analysis which quickly developed. Kelvin's other contributions to tidal theory are also of profound importance. He established (*Phil. Mag.* 1875) the correctness of Laplace's procedure in discussing the dynamical theory of the tides of an ocean covering the whole earth. He introduced (*Proc. Roy. Soc.* Edinburgh, 1879) the rotation of the

earth into the tidal dynamics of small seas, and thus accounted for the transverse surface-gradients across narrow seas. He produced the exact solution of the dynamical equations for a channel of uniform depth when there is no transverse component of current, and indicated the characteristics of tidal motion in a circular basin of uniform depth (§ 19). In 1872 he designed the tide-predicting machine (§ 26).

In 1874 W. Ferrel of the U.S. Coast and Geodetic Survey published his *Tidal Researches* which included a harmonic development of the generating potential; in the same year A W. Baird of the Survey of India organized a service of observation and harmonic analysis for Indian tides (*See* his *Manual of Tidal Observations*); and in 1882 G. H Darwin produced memoirs (*Brit. Ass. Reports,* 1883, '84, '85, '86) which formed the standard manual on the subject. They contained an elaborate analysis of the generating potential and a complete treatment of the methods of analysing hourly heights He afterwards developed methods of analysing observations of high and low water and designed his "tidal abacus" (*Proc Roy Soc.* 1892).

About this time J. E. Pillsbury of the U S Coast Survey began the observations with current meters In 1885 C Börgen introduced new ideas into the methods of harmonic analysis, and these have since been developed in Germany (*See* K Hessen, *Ann der Hydrog* 1920) Between 1870 and 1890 F. A Forel (see *Le Leman*) made illuminating studies of the seiches (§ 17) of Lake Geneva About 1890 M. Margules (*Sitz. Ber. Akad. Wiss. Wien.* 1892–93) investigated the dynamics of atmospheric tides

5. In 1895 H Lamb published the second edition of his *Hydrodynamics* which gave a mathematical account of the dynamical theory His most important original contributions were on the theory of steady motions and free oscillations of the second class, but he also developed the theory of circular basins (§ 19) In 1896 the two memoirs of H Poincaré "Sur l'équilibre et les movements des mers" appeared (*Journ de Math*); and in 1897 S S Hongh produced his two memoirs "On the applications of harmonic analysis to the dynamical theory of the tides," in which he greatly augmented the treatment for an ideal ocean covering the whole earth (§ 19)

From 1894 to 1907 R A Harris of the U S Coast Survey published his *Manual of Tides;* the work contained much on the dynamical theory and charts showing co-tidal lines for the whole world and based on hypotheses, the leading feature of which was the principle of resonance It was assumed that in each ocean there exist regions capable of free oscillation with a period near one of the principal tidal periods, and that the nature of these free oscillations may be calculated approximately He developed the theory of amphidromic points, gave satisfactory general explanations of the tides in a number of narrow seas and considered features of local coastal origin In 1904 and 1905 G. Chrystal (*Roy. Soc. Edinburgh, Proc* and *Trans.*) published his mathematical work on the longitudinal seiches of lakes. About this time a number of Scandinavian oceanographers, notably V. W. Ekman, O Pattersson and J. P. Jacobsen invented current meters, and the records taken with these have been subjected to harmonic analysis. A few years later L. Favé observed tidal elevations in the open sea by means of his self-registering instrument

Recent Research on Water-tides.—6. In 1910 H Poincaré published his *Théorie des Marées.* This theory was further developed by G. Bertrand in 1923 (*Ann. Ecole Normale*). In 1912 A. Blondel (*Ann. Fac. Toulouse*) applied the narrow sea theory, through the principle of least action, to the tides of the Red sea. From 1913 to 1920 R. Steineck (*Acad. Wiss. Wien., Sitz. Ber* and *Denk.*) and A. Defant (*Ann. der Hydrog*) developed the narrow sea theory, as sketched in § 16, with special reference to the Adriatic sea, Defant (*Akad. Wiss. Wien, Denk.* and *Sitz. Ber.*) applied this theory to the Red sea, the Persian gulf, the English channel and the Irish sea (parts of fig. 4 are based on his work), and Steineck (*Sitz. Ber. Akad. Wiss. Wien.* and *Ann. der Hydrog.*) applied extensions to the theory of the tides of the Mediterranean and Black seas. In 1914 J. Proudman gave a direct mathematical process for integrating Chrystal's differential equation without approximating to the normal curve in Chrystal's manner This method was applied to Lake Geneva by A. T. Doodson, R M Carey and R Baldwin in 1920 (§ 15) In 1914 G R Goldsbrough worked out the details for polar and zonal oceans of uniform depth (§ 19) In 1917 J Proudman (*Proc. Lond. Math. Soc*) specified the tidal state of an ocean by means of an infinite number of co-ordinates of the Lagrangian type, and then transformed the differential equations into an infinite set of linear equations.

In 1918 G J Taylor (*Phil Trans. A.*) made a numerical estimate of the rate of dissipation of tidal energy in the Irish sea, and H Jeffreys made the estimate of total dissipation referred to in § 21. In 1920 G J Taylor gave the solution of the dynamical equations for the reflection of a Kelvin wave at the head of a rectangular gulf and for a rectangular basin, the problems mentioned in §20 E Fichot (*Comptes Rendus*) has written several papers on amphidromic regions In 1923 A Defant (*Ann der Hydrog*) produced a co-tidal chart of the North sea derived from a knowledge of the currents by means of the equation of continuity. In the following year J. Proudman gave the method of calculating elevations from currents (§ 15), and A. J. Doodson produced the co-tidal chart for the North sea (*see* references in *Phil. Trans* A) In 1925 J Proudman gave the theory of tides in a channel of non-uniform depth (*Phil Mag*) sketched in § 19, and a mathematical discussion of the effects of capes, bays and islands on local tides (*Mon Not R A S Geoph. Supp.*) In 1927 G R Goldsbrough produced the dynamical theory of tides in an ocean bounded by two meridians referred to in § 20, and A T Doodson described his methods of analysis of observations

TIDAL OBSERVATION

7 Complete investigation of the laws of tidal oscillation demands that the height of the water should be measured at times other than those of high and low water The simplest sort of observation is to note the height of the water on a graduated staff fixed in the sea, with such allowance for wave motion as may be possible; but when extensive observations are to be made an automatic and continuous *tide-gauge* is generally used A well or tank is built on the shore, communicating by a pipe with the sea at some depth below lowest low water mark A float rests on the surface of the water in the well and hangs by a high wire or chain This wire is wrapped round a wheel and imparts to it a rotation proportional to the rise and fall of the tide, which by means of a simple gearing, moves a pencil to and fro against a slowly revolving drum thereby tracing the tide-curve A number of attempts have also been made to construct a self-registering gauge which, when placed on the bottom of the sea, will give a continuous record of the pressure of the water above it.

Tidal currents have mostly been measured by noting the distance moved by a floating log in a definite interval of time, but series of observations at frequent intervals, especially of currents below the surface are usually made by *current-meters* One of the commonest of these, the Ekman meter, registers the mean speed and direction of the current, the former by means of a small propeller actuating a revolution-counting apparatus, and the latter by a vane attached to an apparatus dropping shot into sectorial boxes on a compass card

Astronomical Correlation.—8 The times of high water are found to bear an intimate relation to the positions of the moon and sun The period of 12 hr 25 min is half that of the moon's apparent revolution round the earth The length of time between the moon's crossing of the meridian of a place and the next high water at that place is known as the *lunitidal interval* for the place. The interval takes its average value a day or so after new and full moon and after the first and third quarters The average value of the lunitidal interval on the days of new and full moon is known as the *establishment of the port.*

The range of tide may be similarly correlated. In British waters it reaches its maximum a day or so after full moon and its minimum a day or so after the quarters. In these circumstances the maximum tides are known as *spring tides,* and the minimum tides as *neap tides.* About the time of the equinoxes spring tides are generally larger, and about the time of the solstices generally

smaller than usual. The average interval between new or full moon and the next following spring tides is known as the *age of the tide*. At certain places in Canadian waters the chief variation in the range of tide is associated with the varying distance of the moon from the earth, while at others it is associated with the varying declination of the moon. The diurnal inequality is always associated with the declination of the moon or sun. The most complete correlation between the tides and astronomical variable is provided by the harmonic methods (§ 13).

TIDE-GENERATING FORCES

9 By the law of gravitation the force directed towards the moon's centre on any particle is jointly proportional to the masses of the particle and of the moon, and inversely proportional to the square of the distance between the particle and the moon's centre. If we imagine the earth and ocean sub-divided into a number of small portions or particles of equal mass, then the *average*, both as to direction and intensity, of the forces acting on these particles is equal to the force acting on that particle which is at the earth's centre. For, if we divide the earth into two portions by an imaginary spherical surface passing through the earth's centre and having its centre at the centre of the moon, the portion remote from the moon is a little larger than that towards the moon, but the nearer portion is under the action of slightly stronger forces, so the resultant effects on the two portions are equal It is departure of the force acting on any particle from the *average* which constitutes the tide-generating force. On the side of the earth towards the moon the departure from the average is a small force directed towards the moon; and on the side of the earth away from the moon the departure is a small force directed away from the moon The tidal forces tend to pull the water towards and away from the moon, and to depress the water at right-angles to that direction (*See* fig 1.) The relative magnitudes of the forces are given by the numbers on the figure, and are calculated as indicated in § 11 M is in the direction of the moon, V is the point of the earth nearest the moon, DD are the sides of the earth where the tidal force is directed towards the earth's centre.

The separate attractions of the moon at the earth's centre and at a point on the earth's surface are each inversely proportional to the square of the moon's distance, so that the difference between the two, which gives the tide-generating force, is approximately inversely proportional to the cube of the moon's distance The *vertical* component of the tide-generating force coincides in direction with the gravitational force of the earth itself and thus acts as a very slight modification of weight; this component does

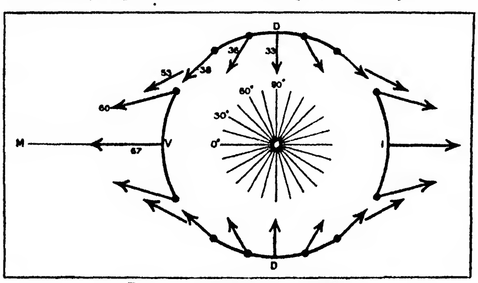

FIG 1—TIDE-GENERATING FORCE

not tend to alter the position of equilibrium which the water would take up in the absence of any disturbance from an extra-terrestrial body. The effective tide-generating forces, therefore, are the *horizontal* components of those indicated in fig. 1, and midway between V and I these are zero.

Equilibrium-form of Tide.—10. For many purposes it is convenient to specify the distribution of tide-generating forces at any instant by reference to a fictitious tide in an ocean covering the whole earth If the earth carried such an ocean and were to remain at rest, and if the tide-generating forces were to remain constant, there would be an invariable elevation of water at each point of the ocean-surface and no tidal currents. If the distribution of forces were the same as that of the actual tide-generating forces at any definite instant, then we might use the consequential elevation of water as a specification of these forces. This distribution of fictitious tidal elevation is known as the *equilibrium-form of the tides*. In this equilibrium-form the inclination to the horizontal of the surface of the water would be always such that the consequential differences of pressure produced horizontal forces balancing the tide-generating forces. It is therefore clear that the surface of the water would slope upwards from DD towards the points V and I, the water being raised by a maximum amount at V and I and depressed by a maximum amount along the great circle through DD perpendicular to the line joining the earth and moon. The surface of the water would be that of a nearly spherical surface of revolution Owing to the motion of the moon relative to the earth, this surface of revolution moves over the earth so that V is always directly opposite, while owing to the varying distance of the moon the surface of revolution changes slightly in shape

The tide-generating forces due to the sun's gravitation may be similarly specified From a consideration of the relative masses and distances of the sun and moon, at corresponding points of the two spheroids representing the lunar and solar equilibrium-forms respectively, the tidal elevations on the average will be in the ratio of 2 17 to 1

Harmonic Constituents of Tide-generating Forces.—At any point of the earth's surface we must represent the sum of the two varying elevations, due to the two moving equilibrium-spheroids, as the sum of a number of constituents that are harmonic functions of the time, *i.e*, terms of form ($H_0 \cos n\ (t-\tau_0)$), where t denotes the time, n is an angular speed, H_0 a length and τ_0 constant The quantity n is the *speed* of the corresponding constituent, it is the same for all points of the earth's surface. The length H_0 is called the amplitude of the constituent at the place in question; H_0 and τ_0 are constant at any one place, but vary over the earth's surface The angle $n(t-\tau_0)$ is called the *phase* of the constituent at time t

If the moon moved with constant angular speed in the plane of the earth's equator and at a constant distance from the earth we should have, at any place, equilibrium high water occurring regularly at intervals of time equal to 12 hr 25 min, with a maximum range of elevation at the equator and a zero range at the two poles Let γ denote the angular speed of the earth's rotation and σ the mean motion of the moon Then the rise and fall of the water would be approximately harmonic, with a speed of $2(\gamma-\sigma)$, so that the equilibrium tide would be represented very approximately by a single harmonic constituent. The fact that the moon does not move as here supposed causes many modifications, the chief of which takes into account the elliptic inequality of her distance giving rise to two new harmonic constituents of speeds $2\gamma-3\sigma+\omega$ and $2\gamma-\sigma-\omega$. The moon's motion also varies in her elliptic orbit, and thus causes the first of these two constituents to be greater than the second.

The moon's movement in a parallel of latitude other than the equator introduces a further new constituent, of speed $(\gamma-\sigma)$, with an amplitude vanishing at the equator. Also, the amplitude of the original constituent, of speed $2(\gamma-\sigma)$, would be less than when the moon was in the equator. Since the declination of the moon changes, this new constituent requires modification. If its amplitude could be regarded as changing harmonically with speed σ, it would be replaced by two harmonic constituents of speeds $\gamma-\sigma\pm\sigma$ Owing to the fact that this is not quite so, the amplitude of the constituent of speed $\gamma-2\sigma$ is greater than that of speed γ. The changing declination of the moon also causes the amplitudes of the semi-diurnal constituents to vary, therefore the speed and range of tide increase or decrease together, and we get yet another new constituent of speed $2(\gamma-\sigma)+2\sigma$. The daily mean level in the equilibrium-form depends upon the particular curve of the spheroid which passes over the place; on this account the changing declination of the moon introduces a constituent of speed 2σ.

The amplitudes of all the constituents depending on the inclination of the moon's orbit to the equator vary with the position of the node on the ecliptic. As the monthly mean level at any place also depends on the inclination of the moon's orbit to the equator, we have a small constituent with a speed $\dot{N}$ equal to that of revolution of the moon's nodes. The speeds of the constituents of solar origin may be similarly determined

Species.—The constituents fall into three species; a *semi-diurnal* species containing the constituents of speeds approximately equal to 2γ, a *diurnal species* containing those constituents of speeds approximately equal to γ, and a *long period species* containing constituents of speeds small compared with γ. Each constituent has a recognized symbol and name.

Symbol	Name	Speed	Coefficient
	Semi-diurnal Species		
M_2	Principal lunar	$2(\gamma-\sigma)$	·454
S_2	Principal solar	$2(\gamma-\eta)$	211
N_2	Larger lunar elliptic	$2\gamma-3\sigma+\omega$	·088
K_2	Luni-solar	2γ	·058
	Diurnal Species		
K_1	Luni-solar	γ	·265
O_1	Larger lunar	$\gamma-2\sigma$	·189
P_1	Larger solar	$\gamma-2\eta$	·088
	Long Period Species		
M_f	Lunar fortnightly	2σ	·078
S_{sa}	Solar semi annual	2η	·036
	Nineteen yearly	$\dot{N}$	·033

In this table η denotes the mean motion of the sun and the coefficients have been calculated as will be explained in § 11

Imagine an equilibrium surface corresponding to each separate harmonic constituent For the semi-diurnal species there will be two maximum and two minimum elevations on the equator, and the elevation will steadily decrease away from the equator reaching zero values at the poles For the diurnal species the elevation will be zero along the equator and at the two poles, but along any other parallel of latitude there will be one maximum and one minimum At any one time all the maxima and minima will lie on two meridians, a maximum changing into a minimum and *vice versa* on crossing the equator For both species the motion of the surface relative to the earth will be one of uniform rotation round the earth's axis with the speed given in the table For a constituent of the long period species, the corresponding surface at any one time will be symmetrical about the earth's axis, and its motion will be a harmonic pulsation with the speed given in the table

11. For the dynamical theory we require a mathematical expression of the geographical distribution of the equilibrium-form in each species of constituent, and for the theory of earth-tides we require the distribution of the generating forces inside the earth as well as over its surface For this purpose we use the *potential* of the forces. A uniform distribution of the average force of the moon's attraction over the whole body of the earth has a potential

$$\frac{\Gamma M}{D^2} r\cos\delta, \tag{1}$$

where Γ = gravitational constant, D = distance from moon C to earth O, M = mass of moon, r = distance of the point P at which potential is evaluated from the centre of the earth, δ = angle COP. The complete potential at P due to the moon's attraction is $\Gamma M/R$, and to get the potential V of the tide-generating forces we have to subtract (1); therefore

$$V=\Gamma M\left(\frac{1}{R}-\frac{r}{D^2}\cos\delta\right)=\frac{\Gamma M}{D^3}r^2(\tfrac{3}{2}\cos^2\delta-\tfrac{1}{2}). \tag{2}$$

on dropping the term $\Gamma M/D$, since it contributed nothing to the forces. If E denotes the mass of the earth, a its radius and g the acceleration of its gravity, we have $g=\Gamma E/a^2$, so that (2) may be written as

$$V=\tfrac{3}{2}g\frac{M}{E}\frac{a^2}{D^3}r^2(\cos^2\delta-\tfrac{1}{3}). \tag{3}$$

Fig. 1 has been constructed from the expression (3). This expression, when $\cos\delta$ is defined in terms of the latitude λ and longitude ϕ of P and the declination Δ and hour-angle α of the moon, gives rise to the semi-diurnal, diurnal and long period species. To find these we must substitute for D and Δ as functions of the time The constituents of the three species then take the respective forms:

$$g\mathbf{H}C\frac{r^2}{a^2}\cos^2\lambda\cos(nt+2\phi-\epsilon),$$

$$g\mathbf{H}C\frac{r^2}{a^2}\sin 2\lambda\cos(nt+\phi-\epsilon),$$

$$g\mathbf{H}C\frac{r^2}{a^2}\tfrac{3}{2}(\sin^2\lambda-\tfrac{1}{3})\cos(nt-\epsilon),$$

where $$\mathbf{H}=\frac{3}{2}\frac{M}{E}\frac{a^4}{D^3}=1\cdot 8\text{ ft.},$$

D_0 being the mean value of D, ϵ denoting a constant for each constituent, and C the numerical coefficient whose value is given in the table of constituents. (G H Darwin, *Brit. Ass. Report*, 1883, A. T Doodson, *Proc Roy Soc* A, 1921) A similar analysis applies to the solar constituents, and the value of **H** will be 460 × 1 8 ft , but in the table of constituents the solar coefficients have been multiplied by ·460 so as to make the coefficients themselves give the relative order of magnitude of both lunar and solar constituents. In certain circumstances the equilibrium-form of tide may provide an approximation to the actual tide, if the "correction for continents" (H H Turner, *Proc. Roy. Soc.* 40) and the modification due to the elevated water itself producing a disturbance in the earth's gravitational field are made (W. Thomson and P G Tait, *Natural Philosophy*, Arts 815, 817; 1879–93)

Equations of Motion.—12 We shall now denote position on the surface of the earth by the co-latitude θ and east longitude ϕ (where $\theta=\frac{\pi}{2}-\lambda$) Let h denote the depth of the ocean at any point so that h is a function of θ, ϕ Also let ζ denote the elevation of the free surface at any point above its mean level, and u, v the southward and eastward components of tidal current, so that these quantities are functions of θ, ϕ as well as of time t. Then the equation of continuity may be written in the form

$$\frac{1}{a\sin\theta}\left\{\frac{\partial}{\partial\theta}(h\sin\theta u)+\frac{\partial}{\partial\phi}(hv)\right\}+\frac{\partial\zeta}{\partial t}=0 \tag{4}$$

In cartesian co-ordinates the equation of continuity takes the form

$$\frac{\partial}{\partial x}(hu)+\frac{\partial}{\partial y}(hv)+\frac{\partial\zeta}{\partial t}=0, \tag{4·1}$$

but, if the elevation is more than a small fraction of the depth of the sea, this equation must be replaced by

$$\frac{\partial}{\partial x}\{(h+\zeta)u\}+\frac{\partial}{\partial y}\{(h+\zeta)v\}+\frac{\partial\zeta}{\partial t}=0. \tag{4·2}$$

Along a *coastline* the equation

$$(\text{depth})\times(\text{current normal to coast})=0 \tag{5}$$

will be satisfied

The *acceleration* of a particle of water will consist of two parts, one due to the rate change of the current relative to the earth and the other to the earth's rotation Except in shallow water and near land the cartesian components of acceleration takes the form

$$\frac{\partial u}{\partial t}-2\omega v,\quad \frac{\partial v}{\partial t}+2\omega u.$$

Dynamical Equations.—It is the kinematical characteristic of tidal motion that vertical accelerations are relatively small, and it is a dynamical consequence of this that the pressure-

intensity at any point depends only on the depth. We therefore see that the southerly and easterly horizontal pressure-gradient at any place will be given by the formulae

$$g\rho\frac{1}{a}\frac{\partial\zeta}{\partial\theta},\ g\rho\frac{1}{a\sin\theta}\frac{\partial\zeta}{\partial\phi},$$

and this at whatever depth these gradients may be required. If we denote by $g\bar{\zeta}$ the potential V of the tide generating forces, then the southerly and easterly horizontal components of these forces will be

$$g\frac{1}{a}\frac{\partial\bar{\zeta}}{\partial\theta},\quad g\frac{1}{a\sin\theta}\frac{\partial\bar{\zeta}}{\partial\phi}$$

per unit mass. The southerly and easterly components of total force per unit mass of water are therefore

$$\frac{g}{a}\frac{\partial}{\partial\theta}(\zeta-\bar{\zeta}),\ \frac{g}{a\sin\theta}\frac{\partial}{\partial\phi}(\zeta-\bar{\zeta}),$$

and the dynamical equations may be written

$$\left.\begin{aligned}\frac{\partial u}{\partial t}-2\Omega\cos\theta v&=-\frac{g}{a}\frac{\partial}{\partial\theta}(\zeta-\bar{\zeta})\\ \frac{\partial v}{\partial t}+2\Omega+\cos\theta u&=-\frac{g}{a\sin\theta}\frac{\partial}{\partial\phi}(\zeta-\bar{\zeta})\end{aligned}\right\}\quad(6)$$

In cartesian co-ordinates the equations take the form

$$\left.\begin{aligned}\frac{\partial u}{\partial t}-2\omega v&=-g\frac{\partial}{\partial x}(\zeta-\bar{\zeta})\\ \frac{\partial v}{\partial t}+2\omega u&=-g\frac{\partial}{\partial y}(\zeta-\bar{\zeta})\end{aligned}\right\}\quad(6{\cdot}1)$$

The form of these equations shows that for the oscillatory motion of the tides the current-components u, v will be the same at all depths

In this argument a number of factors have been left out of account These include the frictional forces at the sea-floor, which itself may be subject to a small variable elevation due to earth-tides.

HARMONIC CONSTITUENTS OF OCEAN TIDES

13 Suppose now that

$$\bar{\zeta}=H_0\cos n(t-\tau_0)$$

as in a single harmonic constituent, H_0, τ_0 being functions of θ, ϕ but not of t Then the solution of the equations (4) (5) and (6) will be of the form

$$\zeta=H\cos n(t-\tau_0),$$

$$u=U\cos n(t-\tau_1),\quad v=V\cos n(t-\tau_2),$$

where H, U, V, τ_1, τ_2, τ_3 are all functions of θ, ϕ, but are independent of t These expressions represent a harmonic constituent of the tides themselves, as distinct from one of the equilibrium-form. At any place the elevation and current-components will vary harmonically with the same speed as the equilibrium-form, though the functions H and τ will in general be quite different from H_0 and τ_0, so that the actual tidal elevation will be quite different from the equilibrium-elevation. Any number of independent solutions of the equations (4), (5) and (6) may be superposed by simple addition, and it follows that for any constituent in the equilibrium-form there will be a constituent of equal speed in the actual tides These constituents are known by the symbols and names already given for the equilibrium-form, and they may be disentangled from the observations of elevations and currents taken at any one place. The dynamical theory here sketched forms the basis of the ***harmonic analysis*** of tidal observations, a process which has been carried out for the elevations at over a thousand stations scattered round the coasts of all the oceans and seas, and for the elevations and currents at a few stations away from the shore in certain shallow seas.

For most places the constituent of largest amplitude is the principal lunar semi-diurnal constituent M_2, as would be expected from the equilibrium-form. When this is the case we may regard the M_2-elevation as the average tidal elevation at the place in question and the other constituents as producing inequalities. Where S_2 is the predominating constituent the average interval between successive high waters will be 12 hours. When M_2 is the largest constituent and S_2 comes next, as in British waters, we have the phenomenon of *spring* tides and *neap* tides. Spring tides occur when the phases of M_2 and S_2 are the same, so that S_2 reinforces M_2; and neap tides occur when these phases differ by 180°, so that S_2 counterbalances M_2 as far as it can. The phase of S_2 gains on that of M_2 at the rate of $2(\sigma\text{-}\eta)$, so that the interval between successive spring tides is half a *synodic month* While S_2 reinforces M_2 the period of the resultant tide is less than the average and we have the phenomenon known as *priming*, whereas while S_2 partly counterbalances M_2 the period of the resultant tide is longer than the average and we have the phenomenon known as *lagging* In the equilibrium-form it is easily seen that spring tides occur at new and full moon and neap tides at the quarters, but in the actual tides these phenomena usually occur a day or two later

When M_2 is the largest constituent and N_2 comes next, as in certain Canadian waters, we have a phenomenon similar to springs and neaps except that it depends on the distance of the moon from the earth Since the phase of M_2 gains on that of N_2 at the rate $\sigma\text{-}\omega$, the period from one reinforcement to the next is an *anomalistic month.* In the equilibrium-form the reinforcement occurs at the time of lunar perigee, but this is not usually the case in the actual tides When M_2 is the largest constituent and K_2 comes next we have a similar phenomenon depending on the declination of the moon The presence of the diurnal constituents gives rise to the diurnal inequality, and when the combined diurnal constituents exceed the combined semi-diurnal constituents we may have only one high water in the day

Geographical Distribution of M_2 Constituent.—14 We shall now indicate the distribution of the principal lunar semi-diurnal constituent M_2 as it has been revealed by harmonic analysis. Along the coasts of the Atlantic, there is a steady progression past the places from South Africa to Nova Scotia, this is rapid in the Gulf of Guinea, slower round Cape Verde and again rapid from Ireland to Iceland Over much of the eastern coast of the United States the M_2 constituent is almost simultaneous, and then along the coast of South America the progression is again northwards. The amplitude is greatest on the coasts of Europe and least in the West Indies. Considering next certain associated seas, on both sides of the English channel and south Irish sea, there is a progression away from the Atlantic, with amplitudes which reach values greater than at places on the open Atlantic. Round the North sea there is a progression southwards along the coasts of Scotland and England, and northwards along the Continental coasts, the amplitude being very small at the south-west corner of Norway. Up the St Lawrence there is a progression away from the Atlantic

Considering next the Indian ocean we exclude the Bay of Bengal and the Arabian sea There is then a progression from Madagascar round by Somaliland, Ceylon, Sumatra and Java to Australia, the amplitudes being small

Along the east coast of the Pacific there is a progression both northwards and southwards away from Lower California, the southerly progression being very rapid round the Central American bay. Following the northerly progression round the northern and western boundaries of the ocean, we come across a number of stretches along each of which the constituent is nearly simultaneous. One is along the Kurile islands and another from the south of Japan to the north-west of New Guinea; another is from the south-east of New Guinea to the north of New Zealand. Along the east coast of Japan there is a relatively slow southerly progression, and along the east coast of New Zealand there is a relatively slow northerly progression. Over the southern ocean the amplitudes are small.

Distribution of Elevation Away from Shore.—15. A convenient method of describing the distribution of the elevation

in a harmonic constituent over an area of the sea is to give on a map the *co-tidal* and *co-range* lines. A *co-tidal* line is one through all points of the sea with the same value of τ, and a co-range line is one through all points with the same value of H. The records from accurate observations of elevations away from the shore, however, are so scanty that they do not form a sufficient basis for a description of the distribution of a harmonic constituent. To give such a description we must have recourse to theory, and when the currents have been well observed this theory is supplied by the fundamental dynamical equations These equations connect the elevation-gradients with the currents and the external forces including those of friction From a knowledge of the currents and a law for the frictional forces the elevation-gradients can be calculated When the elevation is also known at a particular point the directions of the co-tidal and co-range lines and also the distance apart of neighbouring members of these lines can be calculated. Such conditions are fulfilled for many coasts. If the elevation-gradients can be calculated along a line which passes through one or more points at which the elevation is known, methods can be devised by which the elevation can be calculated all along the line. In this way the distribution over the North sea and northern part of the Irish sea as shown in fig 2 have been determined

Tides in small seas open to the ocean are usually such that the actual elevation-gradients are large compared with those of the equilibrium-form, for the equilibrium-range of M_2 only changes by 1·6 ft from the equator to the poles. It follows that over such seas the direct effect of the generating forces is negligible, and this means that the tides of these seas are maintained by those of the oceans It is on the water of the great oceans that the gravitational forces of the moon and sun generate the greater part of the tides To simplify the argument we shall neglect frictional forces; although often important near land, these forces are not as a rule predominant

In the first place we note that the co-tidal line through a point gives the surface contour-line a quarter period (3 lunar hours for M_2) before high water at the point, for at this time the water is at its mean level and the surface contour line runs through points at simultaneous mean level and therefore of simultaneous high water Next we observe that the co-range lines are given by the surface contour lines at high water The dynamical equations then express that the direction of the acceleration is the same as that of the downward surface gradient, and this is perpendicular to the surface contour-line Now at the times of maximum and minimum current the acceleration will be perpendicular to the current. We therefore see that at these times the surface contour-lines will have the direction of the current. If high water occurs at maximum or at minimum current it follows that the co-tidal lines will have the direction of the current at the time of mean level, and that the co-range lines will have the direction of the current at high and low water. If also the maximum or minimum current is parallel to a coastline, one of the two sets of co-tidal and co-range lines will have the coastline for a member while the other will have its members striking the coastline at right angles Now those lines which are perpendicular to the coastline will converge towards a cape and diverge in a bay. An example is afforded by the northern part of the Irish sea Here the minimum currents are practically zero and high water occurs at slack water, so that the co-tidal lines are along the current lines and the co-range lines are perpendicular to the current lines

In a region where the current is non-rotatory, and the co-tidal lines radiate from a point and the co-range lines are similar and similarly situated ellipses with this point as centre, such a point is called an *amphidromic point*. Fig 2 provides two examples in the North sea

Friction.—The frictional resistance of the sea-floor will be directly opposite to the current, and its M_2 constituent will have a magnitude approximately proportional to the square of the magnitude of the M_2 current. When the current at any place reaches a maximum so that the acceleration in its direction is zero, the frictional forces must be balanced by a surface gradient sloping downwards in the direction of the current. For a given current, the magnitude of the slope will be inversely proportional to the depth of the sea. Suppose that the conditions are such that in the absence of friction the maximum current and zero elevation would be simultaneous, as occurs in the broadest part of the Irish sea. Then owing to friction there will be at the time of maximum current a downward gradient in the direction of the current. It follows that mean level will occur progressively later in the direction of the current, and therefore that there will be a progression of high water in this direction

Next suppose that the depth increases away from the shore and that the currents are parallel to the shore. Also suppose that the surface-gradients parallel to the shore are zero at the same time T along a line perpendicular to the shore, as occurs in the North sea between the Forth and the Humber Then in the absence of friction the currents would reach their maximum at the time T, but owing to friction they must have a backward acceleration at this time, and this acceleration will increase towards the shore. It follows that the currents will reach their maximum somewhat before the time T and that the effect will increase towards the shore We thus see that the inshore currents will turn earlier than those in the offing.

Dynamical Explanation of Actual Tides. 16 *The Narrow Sea Theory.*—Let us now consider a sea or ocean and imagine definite limiting vertical sections transverse to the channels which connect it with other seas or oceans Then the tides of this body of water are determined by the equations formulated in § 12 when either the elevations or the normal currents are known functions of time over the limiting sections In explaining the tides in any particular basin it is therefore necessary to assume, either from observation or from other theory, the tidal conditions over the limiting sections. The problem of determination is a purely mathematical one, but hitherto it has only been solved for those seas which are of elongated shape and fairly narrow, with the size and shape of transverse section varying gradually along the length The simplifying principle concerning the tides of such basins is that the transverse components of current are usually negligible, so that the actual currents are non-rotatory and parallel to the general direction of the basin

We will now illustrate this "narrow sea theory" by giving a general explanation of the M_2 constituent in the English channel. The direct action of the generating forces may be neglected, so that the tides of the channel are maintained by those of the Atlantic and North sea We shall leave out of account both the dynamical effects of the earth's rotation and the forces of friction Imagine a fixed material barrier *e* placed directly across the Strait of Dover so as to cut off the currents in that Strait Under these conditions the tides of the channel would consist of a longitudinal standing oscillation (a see-saw motion) maintained by the actual elevations at the Atlantic end and illustrated in fig 2, 8 hr and 11 hr. There would be a nodal line *m* from the neighbourhood of Bournemouth to that of Cherbourg along which there was never any tidal elevation Along a line *w* from Cornwall to Brittany there would be no currents, and we shall take the vertical section through this line to form the western limit of the channel The positions of the lines *m* and *w* are determined by the distribution of depth in relation to the period.

At 8 o'clock in lunar time the surface of the water would be everywhere level, with currents everywhere towards the east, these currents being zero at *e* and *w*, and reaching a maximum at *m*. Three lunar hours later, *i.e*, at 11 o'clock, there would be high water everywhere between *m* and *e* and low water everywhere between *m* and *w*. At 2 o'clock the conditions of 8 o'clock would be reversed, while at 5 o'clock the conditions of 11 o'clock would be reversed The range of tide would increase steadily from zero at *m* to maxima at *e* and *w*, that at *e* being greater than that at *w* on account of the convergence of the channel

Next let us treat the case in which there is no elevation along *w*, so that this line becomes a node With the barrier at *e* there would then be no tides at all, but now let us remove this barrier so that the tides will be entirely maintained by the actual currents in the Straits of Dover. Again they will consist of a longitudinal standing oscillation, but as illustrated in fig 2. 6 hr and

9 hr (two connected half see-saws). At 6 o'clock the surface will be level and the currents will be directed inwards towards *m* from both sides, being strongest in the Strait of Dover. Three lunar hours later, *i e*, at 9 o'clock, there would be high water all over the channel between *e* and *w*, the elevation reaching a maximum near *m* and being zero at *w* and near *e*. At 12 o'clock the conditions of 6 o'clock would be reversed, while at 3 o'clock

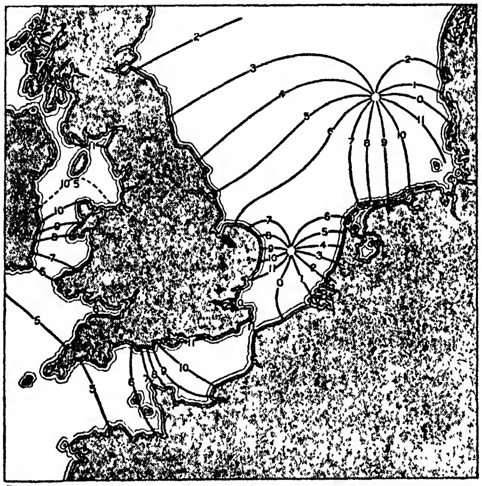

FIG 2.—COTIDAL LINES FOR M_2 CONSTITUENT IN BRITISH SEAS NUMBERS GIVE GREENWICH MEAN LUNAR TIME OF HIGH WATER

the conditions of 9 o'clock would be reversed This time the line *m* would be near a loop and *e* near a node. Now suppose that we superpose these two standing oscillations; we shall have the M_2 constituent of the channel-tides as it would be in the absence of the dynamical effects of the earth's rotation and the force of friction.

The effect of the earth's rotation is to cause an acceleration to the left of the current and proportional to the speed of the current, and when the current does not rotate this means that there must be a downward surface gradient to the left of the current and proportional to the speed of the current On allowing for this effect we arrive at the six diagrams of fig 3, the letter H indicating that the water is above mean level and the letter L that the water is below mean level. The lines drawn across the diagrams of fig 3 separate the regions of H from those of L, and are thus the contour lines at mean level Three lunar hours after the times indicated on each diagram these lines will be lines of either high or low water and therefore co-tidal lines On collecting these lines on to one diagram we have an arrangement of co-tidal lines approximating to those, shown in fig 2 for the English channel and southern Irish sea, which have been constructed from the mathematical form of the "narrow sea theory."

Seiches in Lakes.—This theory of the tides in narrow seas also embraces that of longitudinal seiches in elongated lakes (§ 17). There are many possible values for the periods of seiches, and there is a mathematical process for these values (J. Proudman, *Proc. London Math Soc* 14) which has been applied to the basin of Lake Geneva (A. T. Doodson, R. M. Carey and R Baldwin, *Trans. Roy. Soc. Edinburgh*, 1919), but it is of a complicated nature. Various types of approximation processes have been applied to a large number of lakes, notably to Loch Earn (G. Chrystal and E M. Wedderburn, *Trans Roy Soc Edinburgh*, 1905).

GEOMETRICALLY SIMPLE BASINS

17. In order to elucidate the general characteristics of tides, it is advisable to study the problems presented by the solution of their determining equations when the various conditions which govern them are ideally simple.

Narrow Channel.—We will begin by considering a channel of rectangular section, and neglect both the dynamical effects of the earth's rotation and the force of friction It can be shown mathematically that in these circumstances we reproduce very nearly the longitudinal equations of the narrow sea theory Various simple basins are regarded as particular cases of a channel, in order that the tides therein may be calculated from the narrow seas theory.

In the case of a *gulf* the basin is closed at one end and open to the sea at the other Three distinct types are illustrated in the following examples (a) In a short deep gulf the elevation will everywhere have the same phase as at the open end, and the inward current will have a phase which is $\pi/2$ in advance; also the amplitude of the elevation will increase from the sea to the closed end while the amplitude of the current will decrease from the sea to the end (b) In the Adriatic sea the elevation will have the same phase from the sea up to a certain line, called the *nodal line*, and then the directly opposite phase up to the end The phase of the current will be everywhere $\pi/2$ in advance of that of the elevation at the closed end The amplitude of the currents will increase steadily from the sea to a maximum at the nodal line, and then decrease steadily to zero at the end These relations illustrate to some extent the semi-diurnal constituents of the tides of the Adriatic sea (c) In the bay of Fundy we have the phenomenon of *resonance* which is responsible for the very large tides The case of resonance corresponds to the coincidence of the nodal line with the place at which a definite amplitude of elevation is prescribed

To illustrate *seiches in lakes* we suppose that the basin is closed at both ends. The various types of seiches are distinguished by the number of nodes characteristic of each. In *uni-nodal* seiches the node is in the middle of the basin, and the amplitude of the elevation reaches maxima at the two ends In the *bi-nodal*

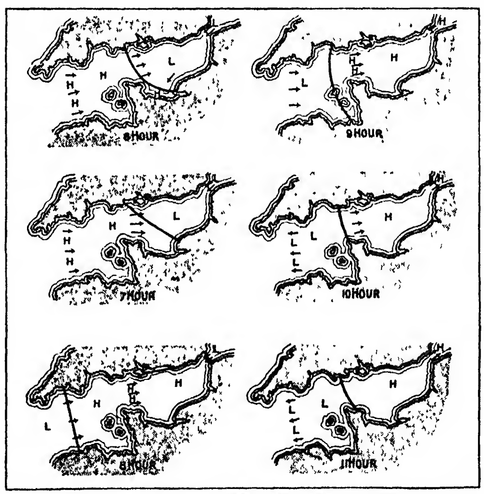

FIG 3.—M_2 CONSTITUENT OF TIDES OF ENGLISH CHANNEL. (H) INDICATES THAT SURFACE IS ABOVE MEAN LEVEL. (L) THAT SURFACE IS BELOW MEAN LEVEL. LINES SHOW SURFACE AT MEAN LEVEL. ARROWS SHOW CURRENTS

seiche the motion in each half of the lake is the same as that of a uni-nodal seiche in the whole lake, while in the *tri-nodal* seiche the motion in each third of the lake is the same as that of a uni-nodal seiche.

The distribution of tides over a gulf, maintained by those in the communicating sea, is similar to the distribution of seiches over part of a lake. The profile of the elevation for a particular time is a wave-form of decreasing amplitude, the greatest height

being at the closed end. The effect of decreasing depth towards the head of a gulf is to produce an increase in the range of tide at the head; the effect of decreasing breadth is of the same kind and more pronounced; but even when taken together the resulting multiplication is by a very moderate factor. The primary cause of the pronounced amplification observed in some gulfs and estuaries is resonance.

In the case of a basin of parabolic longitudinal section, the formula represents the slowest free oscillation, and the vanishing depth at either end of the basin causes no excessive multiplication of range.

Tides in a Lake.—Let us now consider the production of tides in a rectangular lake of uniform depth by the direct action of the generating forces of the moon or sun. There is a nodal line across the middle of the lake, and the distribution of elevation is skew-symmetrical on either side; also the currents reach their maximum on the nodal line. When resonance occurs the period of the disturbing forces is equal to that of a free oscillation or seiche, but such a relation would not hold for the ordinary tides in any actual lake. For certain lakes the equilibrium-form would provide a good approximation to the forced tides.

Long Canals.—18. We next consider a canal of uniform breadth lying *along a meridian* from pole to pole. We shall take the depth to be uniform and suppose the breadth to be sufficiently small for the transverse current off to be negligible. For a semi-diurnal constituent the phase of the elevation is everywhere the same or directly opposite to that of the corrected equilibrium-form; also that the elevation is symmetrical about the equator and that there is a node in latitude 45° N. or S. The maximum current is greatest under the nodes, and takes zero values at the poles and equator. The distribution on each side of the equator is similar to that of a uni-nodal seiche in a lake of uniform section.

Considering next a canal of uniform breadth encircling the earth *along the parallel of latitude,* take the depth to be uniform and again neglect the transverse component of current. For a semi-diurnal constituent the motion consists of a wave travelling round the earth with the same speed as the equilibrium-form, and in fact the phase of the elevation is everywhere either the same as or else directly opposite to that of the equilibrium-form At any place the west-going current reaches its maximum at the time of high water.

Small Seas.—19. Returning to seas over which we may neglect the curvature of the earth, let us take a *broad channel* whose section is uniform along its length, but whose depth may vary from side to side. A wave progressing along the channel with a zero transverse component of current can only exist if the depth be uniform. Such a wave we shall call a "Kelvin-wave" The narrow sea theory is never accurate when the depth is not uniform, but for such a channel it is possible to find an accurate solution representing a wave with straight transverse co-tidal lines Waves with straight transverse co-tidal lines are possible in spite of the variable depth. In them the principal axes of the current ellipses are parallel and perpendicular to the sides of the channel, and the time of the maximum longitudinal component of current coincides with that of high water at the same place. The solution gives the correction to the narrow sea theory for varying depth across the channel; in most actual cases this correction is not very important.

From a mathematical point of view the basin just considered is analogous to a *circular basin* in which the depth is either uniform or a function only of the distance from the centre. We have a wave progressing round the centre of the sea in either direction, or a standing oscillation. The principal axes of the current ellipses will be long and perpendicular to the radii. There is a definite infinite sequence of possible periods, with a longest period but with no shortest period (H. Lamb, *Hydrodynamics,* Art. 210, 1895). The corresponding oscillations are known as "free oscillations of the first class," and so long as the depth is uniform no other free oscillations are possible. When the depth is not uniform there may be in addition to an infinite sequence of oscillations of the first class, analogous to those just investigated, another infinite sequence called "oscillations of the second class." These have a definite shortest period but no longest period (*Ibid.* Art. 212).

Ideal Ocean.—The mathematical relationships of small seas still obtain for an ocean in which the depth is a function only of latitude and the coastlines, if any, lie along parallels of latitude. A special case has already been considered in the canal running round a parallel of latitude. For forced semi-diurnal constituents the motion consists of a wave travelling round the earth like the equilibrium-form. In fact, at any place the phase of the elevation is always either the same or else directly opposite to that of the equilibrium-form. The distribution of range of tide along a meridian, however, will in general be entirely different from that of the equilibrium-form. When the ocean covers the whole earth it is possible to allow for the mutual gravitation of the elevated water without seriously complicating the mathematical problem (S. S. Hough *Phil. Trans* A, 1897). At the poles the range of tide is zero as in the equilibrium-form, and sufficiently near the poles the elevation has the same phase as the equilibrium-form. For very great depths the tides everywhere approach the equilibrium-form.

When the depth is uniform and the ocean covers the whole earth the solution has been subject to much numerical evaluation. The first row in the accompanying table gives a series of depths in feet, and the figures below correspond respectively to oceans of

7,260	14,520	29,040	58,080
7·4	1·8	11·3	1·9
2·4	1·8	11·1	1·9
17 59	14 52	12 1	9 24
38 34	26 54	18 40	12 55

these depths. The second row gives the ratio of the range of the M_2 constituent on the equator to the corresponding range in the equilibrium-form when the mutual gravitation of the elevated water is neglected (H. Lamb, *Hydrodynamics,* Art. 221). The third row gives the same ratio when the mutual gravitation of the elevated water is allowed for. The fourth and fifth rows relate to free oscillations of the first class in the expressions (*cf* § 11) for which t and ϕ enter only through the factor cos $(nt+2\phi-\epsilon)$ and in the calculation of which the mutual gravitation of the elevated water has been taken into account. The fourth row gives in hours and minutes the longest periods of free waves travelling westward; while the fifth row gives in hours and minutes the longest periods of free waves travelling eastward. The shortest periods of the oscillations of the second class are all longer than a day Numerical evaluations of forced tides in a polar or zonal ocean indicate that the actual tides cannot be regarded as derived from tides generated primarily in the southern ocean (G R. Goldsbrough, *Proc. Lond. Math. Soc.* 1913, and *Proc. Roy. Soc* A, 1927).

Other Seas.—20. The above examples exhaust all the instances in which complete solutions of the dynamical equations may be obtained in a simple form when the effects of the earth's rotation are taken into account For seiches, however, of which the periods are small compared with a day, the effects of the earth's rotation are not important, and when these effects are neglected simple solutions are possible for certain other basins. The non-rotating *rectangular basin* of uniform depth, the *sectarial basin* whose depth is a function only of the distance from the apex, and in the case of free tides, an ocean bounded by meridians and parallels of latitude on a non-rotating earth when the depth is a function only of latitude (H. Lamb *Hydrodynamics,* Art 201) are all analogous. The solution for the forced tides in such an ocean has only been given in certain special cases (J. Proudman and A T. Doodson, *Mon. Not R A S, Geophys. Supp.* 1927). The *elliptic basin* of uniform depth possesses types of free motion which are analogous to those of the *circular basin* (H. Jeffreys, *Proc. Lond. Math. Soc.* 1923), the Bessel's functions and trigonometrical functions of the circular basin being replaced by Mathieu-functions.

Rotating Basins.—When the earth's rotation is taken into account the simplest problem not already mentioned is that of the reflection of a Kelvin-wave at the head of a *broad rectangular gulf* of uniform depth. For a given depth and period such a wave

can be reflected into one of the same type travelling in the opposite direction, if the breadth of the gulf is not greater than a certain amount The complete solution (G. J. Taylor, *Proc. Lond. Math. Soc.* 1920) then shows a wave progressing towards the head of the gulf on the one side, continuing round the head, and then away from the head on the other side There are a number of amphidromic points on medial line of the gulf. In the northern hemisphere the progression is such that the coast is always on the right. This arrangement may be compared with the co-tidal lines shown in fig 2 for the North sea The solution gives the correction to the narrow sea theory for a transverse barrier; at a distance from the barrier the correction becomes unimportant.

The solution for the rotating sectorial basin has only yet been given for the semi-circular case and for uniform depth (J. Proudman, *Mon. Not R.A.S. Geophys Supp.* 1926–28), while that for the rotating elliptic basin has only been published for special conditions (S. Goldstein, *Mon. Not., R A S, Geophys. Supp.* 1928). It can be proved, however, that for land-locked seas of small lateral extent, which are not too shallow, the forced tides follow very closely their equilibrium-forms. In these forms the centroid of the area is an amphidromic point

The only ocean on a rotating earth possessing coast lines other than parallels of latitude for which the dynamical equations have yet been solved is one whose depth is proportional to the square of the cosine of the latitude, and which is bounded by two meridians separated by 60° of longitude (G R Goldstein, *Proc. Roy Soc.* A, 1927) This basin has a much closer correspondence with those in which the actual tides are generated than any other for which a numerical solution has yet been given For the K_2 constituent in this basin it is found that the critical mean depth for resonance is 15,500 ft As the mean depth of the Atlantic is 12,700 ft., we have an indication of a considerable amount of resonance, and there can be little doubt that the Atlantic tides are largely generated in the Atlantic ocean itself

GENERAL DYNAMICAL QUESTIONS

21 The observed tides on many coasts of the world are very much larger than their equilibrium-forms, and this has usually been attributed to the magnifying effect of shallow seas Mere diminution of depth, however, even to vanishing point, is not in itself a necessary source of much magnification, so that some form of resonance is required. On the one hand, with mid-ocean tides of the equilibrium-order of magnitude, it is possible to have resonance on the continental shelf if its breadth and depth are suitably related. On the other hand, it is also possible to have a considerable degree of resonance in the main oceans themselves, as is shown by the last of the examples quoted above (§ 20).

All the examples of forced tides quoted above are such as to tend to their equilibrium-forms when their periods tend to become infinite This tendency is due to the special simplicity of the examples considered, and is not a general property of forced tides when the effects of the earth's rotation are taken into account but those of friction are neglected Steady currents are possible if there are any closed contour lines of the depth of the ocean measured parallel to the earth's axis, and the actual oceans do contain such contour lines. The problem of specifying the nature of the solution of the dynamical equations for the case of forced long-period tides is further complicated by the possibility of resonance with the free oscillations of the second class The effects of friction are sufficient to make any forced periodic tide conform to its equilibrium-form if its period is sufficiently long, but a criterion of this length has not yet been satisfactorily evolved. If tidal motion were everywhere non-turbulent, friction would have no appreciable influence on a constituent whose period was less than a year It is known, however, that the resultant motion in shallow seas is turbulent, and it is probable that even in mid-ocean the forces of friction are not less than those calculated on the hypothesis of turbulence.

The total rate of *dissipation* of energy by friction in the actual semi-diurnal tides has been estimated (H Jeffreys, *Phil. Trans.* A, 1920) at about 2×10^9 horse-power The chief contributory areas were found to be Bering sea, the Yellow sea, Malacca strait and the North-west passage, the dissipation in the great ocean basins being supposed negligible in comparison. The problem of estimating the length of time required to destroy the total energy in any constituent, at the rate at which energy is actually being dissipated in that constituent, turns largely on the amount of magnification of tides in shallow seas If, in mid-ocean, the semi-diurnal constituents were of their equilibrium-order of magnitude, then the time required would be only about two days (H Jeffreys, *Nature* 1923)

Compound Constituents.—22 So far in our discussion of tidal dynamics we have neglected certain terms in the dynamical equations The effect of this has been to make the differential equations linear, and it is the linearity of the equations which allows of the separation into independent harmonic constituents. Such a neglect, however, is not always admissible, especially in shallow water and near rugged coast lines. Suppose that over a region there is a predominant harmonic constituent, *e g.*, M_2 of speed n; then the effect of the retention of these terms will be that the time will enter in such a form that terms which contain the time-factor represent a constituent of double the speed of the primary constituent, while others represent a steady motion or displacement. The first of these is known as a *first overtide*, and when derived from M_2 is called M_4 Again, if the principal part of the tides comprises two harmonic constituents, then in addition to overtides we have terms which represent constituents of speeds n_1+n_2 and n_1-n_2 When the primary constituents are M_2 and S_2 they are denoted by MS_4 and MS_f respectively Since the force of friction at the sea-floor is not proportional to the speed of the current, there is also a frictional origin of compound constituents. Further approximations would give *second* and *third overtides*, etc

All the overtides travel up a canal, of uniform breadth and depth, indefinite length and communicating with the sea, at the same rate as the fundamental but they have double, treble, quadruple, etc, speeds If the canal shallows very gradually, the height of the overtide varies as (depth)[illegible]. Fig 4 read from left to right, exhibits the progressive change of shape. The steepness of the advancing crest shows that a shorter time elapses from low water to high water than inversely.

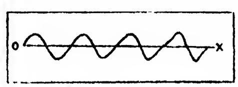

FIG 4 --PROFILE OF TIDE-WAVE IN CANAL

ATMOSPHERIC AND EARTH TIDES

Atmospheric Tides.—23. As air, like all other matter, is subject to gravitational influence, there will be tides in the atmosphere possessing many features of similarity with those in the ocean. One of the characteristics of these tides will be a very small oscillatory variation in the atmospheric pressure at any place, and this may be regarded as the superposition of harmonic constituents with the ordinary tidal periods. By the systematic analysis of long series of regular barometric records the principal lunar semi-diurnal constituent M_2 of the barometric variation has been determined for a number of places, and found to have an amplitude of the order ·001 inch. The dynamical theory of these tides has been the subject of considerable study. The derivation of the equations is not so simple as for ocean tides, one difficulty being that of taking account of the physical conditions in the upper regions. The equations which have been proposed are of the same general form as those for ocean tides, but the theory is still imperfect.

The results of analysis for the M_2 constituent show variations of phase from place to place and certain seasonal changes which are as yet unexplained. The results of analysis for the S_2 constituent show a much larger oscillation with an amplitude of barometric variation of the order ·03 inch. For this constituent, however, it is certain that thermal factors play a large part though the theory is far from complete (S. Chapman, *Quart. Journ. R Met. Soc.*, 1918–19–24).

Earth-tides.—24. The main body of the earth yields to tidal

forces, either with perfect or imperfect elasticity, and these minute tides of the solid earth have been measured. The measurement of earth-tides consists in determining the tilt of the earth's surface about its mean position in the earth's figure, and this has been carried out with apparatus of two kinds. One instrument, viz., the horizontal pendulum (O. Hecker, *Veroff K. Preussischen Geod. Inst.* 1907), is of a type also used in seismology. Its action is analogous to that of a door whose hinges are not exactly one above the other, so that it lies in a definite vertical plane depending on the position of its line of hinges. The other instrument consists of a horizontal tube, of length from 100 to 500 ft., acting as a water level and read by optical interferometer devices (A. A. Michelson, *Astrophys. Journ* 1914) It should also be possible to detect earth-tides by means of observations of ordinary water-tides, but in the absence of full observational knowledge of water-tides over a region we must have recourse to a certain amount of theory

Up to the present the method which has been adopted has utilized the ocean-tides of long period and in particular the lunar fortnightly constituent M_f. It has been assumed that this constituent follows the equilibrium law, and this is not certain, while in addition there is the fact that the complete equilibrium-form has not yet been numerically calculated There is a further serious difficulty in isolating the purely astronomical long-period constituents in analysis, and it may well be doubted whether reliable constants for the M_f constituent have ever yet been obtained from the records of observation

When we come to consider the dynamical theory of earth-tides we see that there are various factors involved. There is the direct response of the solid earth to the tide-generating forces of the moon and sun; there is the yielding produced by the varying pressure of the tidal load on the ocean-floor; there is also the yielding to the earth's varying gravitational field itself, as produced by the moving water and solid earth (A. E. H. Love, *Some Problems of Geodynamics*, 1911). These factors have not yet been completely disentangled from the results of observation. The period of the slowest free tidal oscillation of a homogeneous sphere, of the same radius and mass as the earth and as rigid as steel, is about one hour (H. Lamb, *Proc. Lond. Math Soc.* 1882). The corresponding period for a homogeneous fluid sphere, of the same size and mass, is about one and a half hours (W Thomson, *Phil. Trans.* 1863). It is, therefore, probably correct to assume that the periods of the free oscillations of the actual earth are all small compared with those of the chief constituents of the tides. This means that the earth tides will approximate closely to their equilibrium-forms, or, in other words, that they may be calculated on the principles of statics.

For an earth of uniform density and elasticity and with an ocean of uniform depth over the whole of it, a complete solution of the tidal problem, both ocean and earth, has been obtained (R O. Street, *Mon. Not R A S*, *Geophys. Suppl.* 1925). For the simpler case in which there is no ocean, if the mass be that of the actual earth and the assumed rigidity be that of steel, the earth-tide would be everywhere equal to $\frac{1}{3}$ of the equilibrium ocean-tide, while if the rigidity be that of glass the fraction would be $\frac{2}{5}$. Such determinations as have yet been made indicate that the effective rigidity of the earth as a whole is somewhat greater than that of steel (W. D. Lambert, *Bull. U.S. Nat. Research Council*, 1922).

ANALYSIS OF OBSERVATIONS AND PREDICTION

25. The tide-gauge furnishes us with a continuous graphical record of the level of the water above some known datum mark for every instant of time. The first operation performed on this record is the measurement of the height of water above the datum for every mean solar hour. In analysis it is necessary that these hourly heights be combined in such a way as to magnify one constituent relatively to all others, and in practice only linear combinations are used. The complete process of finding all the important constituents may be carried out in two stages, in the first of which simple linear combinations are made, and in the second, essentially a correction process, the results of all the linear combinations for all the constituents are used.

Process of Finding Constituents.—We will restrict our consideration to the problem of determining the principal solar series of constituents S_1, S_2, S_4, whose speeds are exactly 24, 12, 6, mean solar hours. At instants of time separated by 24 hours each constituent of this series will have the same value. If then we calculate the average of the heights at the same hour of each solar day, the corresponding value of each of these constituents will be unchanged. Any other constituent, however, will occur in a different phase each day, so that the algebraic additions will partially counterbalance, and if the number of days taken extend over a year the average value for a particular hour of a solar day will be very small. If such an averaging process be carried out for each of the 24 hours of the day we have a method of isolating the principal solar series. When this series has been isolated with sufficient completeness, the amplitudes and initial phases of its constituents may be determined in a number of ways (*see* HARMONIC ANALYSIS)

The process just sketched has been much followed in actual practice, especially in the early days of harmonic analysis of tidal observations. When applied to constituents other than those of the principal solar series it becomes less simple, as it is impossible to choose an interval of an exact number of mean solar hours which gives perfect repetition in the values of any other constituent. A common practice has been to treat the height at any mean solar hour as though it occurred at another time not differing by more than half an hour It is clear, however, that the effect on any constituent of any definite arithmetical process may be accurately determined, and this had led to important modifications in the processes of analysis In designing these modifications the criteria in mind have been: (1) the amount of labour involved, (2) the degree of elimination of all other constituents in the analysis for a particular constituent and (3) the completeness of the analysis (A. T. Doodson, *Phil. Trans.* A, 1927). Similar methods will serve for the analysis of a continuous record of a particular component of tidal current. Methods have also been devised for the harmonic analysis of observations of times and heights of high and low water only (G H. Darwin, *Proc Roy. Soc.* 1890), and even for the observations of times of slack water only

Even when the most complete methods are utilized on the most carefully made observations, there remains quite an appreciable fraction of the apparently periodic variation of sea-level which has not yet been reduced to law. For British waters this reaches the order of magnitude of a foot, and consists of something lying outside the harmonic constituents with the periods of the generating potential or of a small number of compound constituents (A. T Doodson, *Brit. Ass. Report*, 1921) The nature of this residue has not yet been satisfactorily determined; although of tide-like periodicity, part of it is possibly of meteorological origin The variations of atmospheric pressure and wind produce changes in the level of the sea Under favourable conditions, and as a consequence of storms, the change of level in an estuary may exceed 6 ft Since such changes are not periodic they are not represented by the results of harmonic analysis

Prediction.—26 For many purposes it is of great importance to know in advance the times and heights of high water at a particular place on a particular day. Consequently governments and harbour authorities publish, a year or so in advance, *tide tables* giving such information for all the principal ports of the world In a few cases tables are similarly published giving the height of water above datum at every hour of the year, while for a certain number of navigable channels tables of the times of slack water are also issued. The determination of the information contained in these tables is known as tidal prediction, and obviously demands a knowledge of the laws of the tides at the place in question, including their correlation with astronomical variables

The standard method of tidal prediction is the harmonic method based on the idea of harmonic constituents (§ 13), and the necessary information for any particular place is provided by the process of harmonic analysis. For a number of ports, however, some of which are in British waters, it is found practicable to use the older non-harmonic methods based on the non-harmonic con-

stants. In any case, the only part of the dynamical theory which is utilized is that which relates to periodicity at one place, so that the empirical element is still very large.

Predicting Machine.—The process of ***harmonic prediction*** consists in the calculation of the value of each harmonic constituent for a given time and then the addition of the values obtained for all the constituents. When this is done for every hour of a year the computational task becomes enormous, and a calculating machine has been designed to obviate it. Fig. 5 illustrates diagrammatically the nature of the instrument. A cord passes over and under a succession of pulleys, every other pulley being balanced in a fixed position and the alternate ones being movable; the cord is fixed at one end and carries at the other a pen which traces a curve on a revolving drum In the diagram the instrument possesses one unit; there are two balanced pulleys and one movable one. If the lowest or movable pulley were made to oscillate up and down with simple harmonic motion, the pen would execute the same motion on twice the linear scale If the instrument possessed two units, *i e*, one additional movable and one additional balanced pulley, and the second movable pulley also rocked up and down, the pen would add to its previous motion that of this second oscillation on twice the scale. For any number of additional units the pen would add together all the separate simple oscillations The rocking motion is communicated to each movable pulley by means of a pin P, attached to a fixed point of the wheel of centre C and sliding in a slot attached to the pulley-frame. All the wheels C and the drum are geared together, so that, as the drum turns, all the movable pulleys rock up and down The gearing is of such a nature that, if one revolution of the drum represents a single day, the rocking motion of each movable pulley corresponds to one harmonic constituent. The nature of the gearing is determined by the relative speeds of the different constituents, but the length of each crank CP and the angle at which it has to be set are derived from the results of harmonic analysis. When the machine has been set appropriately it will run off a complete tide-curve for any length of time.

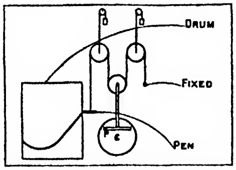

FIG 5 —TIDE-PREDICTING INSTRUMENT

Of course the irregular meteorological effects on sea level cannot be incorporated in a tide-table, and hence any individual prediction is liable to differ considerably from the actual occurrence. For the utilization of the energy of tides *see* TIDAL POWER.

TIDORE or **TIDOR,** a mountainous island of the Moluccas, D E. Indies, lying south of Ternate, nearly circular in shape, with an area of about 30 square miles. The southern part is occupied almost entirely by an inactive volcanic peak (5,900 ft.). Below the 1,000 ft. level coffee, fruit and tobacco are cultivated, the soil being very fertile. The northern half consists mostly of hills, though there are a few level strips along the coast. Pop., 31,832. Tidore is part of the residency of Ternate, and, with neighbouring islands, comes under the resident of Ternate. The inhabitants are akin to the Ternatans. They dislike work, but sell fish and cultivate garden produce. Some Tidorese do smiths' work, in which they are proficient.

The other islands of the Ternate-Tidore group are Hiri, Mayu, Taifore, Maitara, Pilonga, Maré, Pasuraja, Moti, Makian, Waidoba, Taneti and the Kayua and Goraityi groups. All stretch along by the coast of Halmaheira towards Bachian, with the exception of Taifore and Mayu, which lie out in the Molucca passage. Kayua (of coralline and crystalline rock formation), is nearly 10 m. long and has a mountain range traversing most of its length. The people are Mohammedans, and grow rice and maize, and fish. Makian has a mountain over 4,000 ft., is well-wooded, volcanic, and has suffered from eruptions. It has a population of over 8,000 Mohammedans, resembling the people of Ternate and Tidore, who weave, fish and grow tobacco, fruit, rice and sugar-cane. Sago, the staple food, is imported from Halmaheira. Moti is surrounded with coral reefs. Maitara has mountains which attain an elevation of nearly 3,000 ft., and is well forested and fertile.

Like Ternate, Tidore is the seat of an ancient and once powerful sultanate. The Portuguese established themselves there in 1521 and fought the sultan, whose capital they destroyed Later, the Spaniards, when Portugal had become incorporated with Spain, obtained a hold which they retained until well into the 17th century, aiding the Tidorese in maintaining their independence in Ceram, Halmaheira and other islands, against the sultan of Ternate and the Dutch. The latter, in 1654, conquered the island, but the nominal power of the sultan was (and still is) recognized by the Dutch Government (E. E L)

TIDY TIPS (*Layia platyglossa*), a small North American herb of the family Compositae, native to California. It is an attractive spring-blooming annual, about a foot high, bearing showy flowering heads, $1\frac{1}{2}$ in. broad, with sulphur-yellow rays tipped with white. This plant and other related Californian species, as *L elegans,* are grown as garden annuals. The white-flowered *L. glandulosa,* found from British Columbia to Mexico, is also cultivated.

TIECK, JOHANN LUDWIG (1773–1853), German poet, novelist and critic, was born in Berlin on May 31, 1773, his father being a rope-maker. He was educated at the Friedrich-Werdersche Gymnasium, and at the universities of Halle, Göttingen and Erlangen. At Göttingen Shakespeare and the Elizabethan drama were the chief subjects of his study In 1794 he returned to Berlin, resolved to make a living by his pen. He contributed a number of short stories (1795–1798) to the series of *Strauss-federn*, published by the bookseller C. F. Nicolai and originally edited by J. K. A Musäus, and wrote *Abdallah* (1796) and a novel in letters, *William Lovell* (3 vols. 1795–1796). Tieck's transition to romanticism is to be seen in the series of plays and stories published under the title *Volksmärchen von Peter Lebrecht* (3 vols., 1797), a collection which contains the admirable fairy-tale *Der blonde Eckbert*, and the witty dramatic satire on Berlin literary taste, *Der gestiefelte Kater*. With his school and college friend W. H. Wackenroder (1773–1798), he planned the novel *Franz Sternbalds Wanderungen* (vols. i.–ii. 1798), which was the first expression of the romantic enthusiasm for old German art.

In 1801 Tieck went to Dresden, then lived for a time near Frankfort-on-the-Oder, and spent many months in Italy. In 1803 he published a translation of *Minnelieder aus der schwäbischen Vorzeit,* between 1799 and 1804 an excellent version of *Don Quixote,* and in 1811 two volumes of Elizabethan dramas, *Altenglisches Theater.* The stories *Der Runenberg, Die Elfen, Der Pokal,* and the dramatic fairy tale, *Fortunat,* with earlier works, appeared in the collection *Phantasus* (3 vols., 1812–17). In 1817 Tieck visited England in order to collect materials for a work on Shakespeare (unfortunately never finished) and in 1819 he settled permanently in Dresden; from 1825 on he was literary adviser to the Court Theatre, and his semi-public readings from the dramatic poets gave him a reputation which extended far beyond the Saxon capital. The new series of short stories which he began to publish in 1822 also won him a wide popularity. Notable among these are *Die Gemälde, Die Reisenden, Die Verlobung, Des Lebens Überfluss.* More ambitious and on a wider canvas are the historical or semi-historical novels, *Dichterleben* (1826), *Der Aufruhr in den Cevennen* (1826, unfinished), *Der Tod des Dichters* (1834), *Der junge Tischlermeister* (1836; but begun in 1811), an excellent story written under the influence of Goethe's *Wilhelm Meister. Vittoria Accorombona*

(1840), in the style of the French Romanticists, shows a falling-off. In later years Tieck carried on a varied literary activity as critic (*Dramaturgische Blätter*, 2 vols., 1825–1826; *Kritische Schriften*, 2 vols., 1848); he also edited the translation of Shakespeare by A. W Schlegel, who was assisted by Tieck's daughter Dorothea (1799–1841) and by Graf Wolf Heinrich Baudissin (1789–1878); *Shakespeares Vorschule* (2 vols , 1823–1829); the works of H. von Kleist (1826) and of J. M R Lenz (1828). In 1841 Friedrich Wilhelm IV of Prussia invited him to Berlin where he enjoyed a pension for his remaining years He died on April 28, 1853.

Tieck's *Schriften* appeared in 20 vols. (1828–46); and his *Gesammelte Novellen* in 12 (1852–54) *Nachgelassene Schriften* were published in 2 vols in 1855 Of modern editions of *Ausgewahlte Werke see* those by G Klee (with an excellent biography, 3 vols, 1892), and G Witkowski (4 vols, 1903). *The Elves* and *The Goblet* were translated by Carlyle in *German Romance* (1827), *The Pictures* and *The Bethrothal* by Bishop Thirlwall (1825). *See* for Tieck's earlier life R Kopke, *Ludwig Tieck* (2 vols, 1855), for the Dresden period, H von Friesen, *Ludwig Tieck · Erinnerungen* (2 vols, 1871), also A Stern, *Ludwig Tieck in Dresden* (*Zur Literatur der Gegenwart*, 1879); B Steiner, *L Tieck und die Volksbucher* (1893); H Bischof, *Tieck als Dramaturg* (1897); H Luedeke, *L Tieck und das alte englische Theater* (Frankfurt, 1922); A. E. Lussky, *Tieck's approach to Romanticism* (Borna-Leipzig, 1925).

TIEL, a town in the province of Gelderland, Holland, on the right bank of the Waal (here crossed by a pontoon bridge), 25 m by rail west of Nijmwegen Pop (1927), 12,123 It possesses fine streets and open places, but of its fortifications the Kleiberg gate (1647) alone remains The principal buildings are St. Martin's church (15th century), the town hall, court-house and the historical castle of the family of van Arkel

TIELE, CORNELIS PETRUS (1830–1902), Dutch theologian and scholar, was born at Leiden on Dec 16, 1830 He was educated at Amsterdam high school and afterwards at the seminary of the Remonstrant Brotherhood He was destined for the pastorate in his own brotherhood Tiele certainly had liberal religious views himself, which he early enunciated from the pulpit, as Remonstrant pastor of Moordrecht (1853) and at Rotterdam (1856) Upon the removal of the seminary of the brotherhood from Amsterdam to Leiden in 1873, Tiele was appointed one of its leading professors In 1877 followed his appointment at the university of Leiden as professor of the history of religions, a chair specially created for him. Of his many learned works, the *Vergelijkende geschiedenis van de egyptische en mesopotamische Godsdiensten* (1872), and the *Geschiedenis van den Godsdienst* (1876, new ed 1891), have been translated into English, the former by James Ballingall (1878–1882), the latter by J. Estlin Carpenter (1877) under the title "Outlines of the History of Religion" (French translation, 1885; German translation, 1895) A French translation of the *Comparative History* was published in 1882 Other works by Tiele are: *De Godsdienst van Zarathustra, van het Ontstaan in Baktrie, tot den Val van het Oud-Perzische Rijk* (1864) a work now embodied, but much enlarged and improved by the latest researches of the author, in the *History of Religions* (vol. ii. part ii., Amsterdam, 1901), a part which appeared only a short time before the author's death; *De Vrucht der Assyriologie voor de vergelijkende geschiedenis der Godsdiensten* (1877; German ed , 1878); *Babylonisch-assyrische Geschichte* (two parts, Leipzig, 1886–1888); *Western Asia, according to the most Recent Discoveries* (London, 1894) He was also the writer of the article "Religions" in the 9th edition of the *Ency Brit* He died on Jan. 11, 1902

TIEN-SHAN or CELESTIAL MOUNTAINS, one of the most extensive mountain systems of Central Asia. In the widest acceptation, the system extends from the Aral-Caspian depression (about 67° E.) to the great bend of the Hwang-ho (about 103° E.). Chinese geographers confine the term to that part between Khan-tengri (80° 11′ E. and 42° 13′ N.) and the Barkul depression (92°–93° E.), where the northern ranges abut upon the Ek-tagh Altai; and this conception is accepted by some European geographers. P. P. Semenov applies the name to the ranges which lie immediately west of Khan-tengri, including Khan-tengri. The Tarbagatai and their north-western continuation, the Chinghis mountains, are sometimes considered to belong to the Altai system; but there are good reasons for regarding them as an independent range. Excluding these, the northernmost member of the Tien-shan system is the Dzungarian Ala-tau (45° N.), the southernmost, the Trans-Alai, or rather its west prolongation, Peter the Great Mountains in Karateghin (Bukhara), though some geographers assign both the Alai and the Trans-Alai Mountains to the Pamirs.

Khan-tengri and the Central Tien-shan.—The peak of Khan-tengri (22,440 ft) stands but on a spur which projects from the main watershed of the central Tien-shan, towards the south-west. The loftiest summit on the actual watershed is named Nicholas Mikailovich (22,670 ft). The general altitude of the crest of the watershed is about 16,500 ft , and it is overtopped by peaks rising 3,000–3,500 ft. higher. East of Khan-tengri is Khalyk-tau, and west three diverging lines of elevation, viz , the Terskei Ala-tau; the Kokshal-tau, continued in the Terez Mountains; and, between these two, the successive ranges of the Sary-jas, Kulu-tau, and Ak-shiryak. The snowy chain of Khalyk-tau is highest in the west and sinks gradually towards the east The highest parts of the range have generally an east-west strike and the range itself is continued east in the Kokteke (12,300 ft), with the Kui-kuleh pass at 11,500 ft

From Issyk-kul there is a sharp rise of 6,000–9,000 ft to the snow-capped ridge of the Terskei Ala-tau, the peaks of which ascend to 15,000–16,500 ft and even 18,000 ft. At this part the system has a breadth of 150 m The Terskei Ala-tau forms a sharp, continuous, snow-clad range. It is continued westwards in the Son-kul (alt. 9,500 ft), the Kara-kol, and the Suzamir-tau, until it abuts upon the Talas-tau. There are broad shallow basins south of the Terskei Ala-tau and between them from five to seven ridges as broad as the basins The ridges rise to 13,000–16,000 ft by long gentle slopes, are flat topped and snow covered with a few individual peaks and high passes. Being an uplifted peneplain and little or no erosion having taken place since late Tertiary times, the result is that although highly mountainous, in external appearance the district is that of a plateau The passes over the Terskei Ala-tau and the country to the south lie at great altitudes—Kulu-tau (13,560 ft), Bedel (13,800 ft), Kubergenty (12,400 ft.), Terekty (12,600 ft) and Jan-art (14,440 ft)—all in the Kokshal-tau, Terek (12,800 ft) and Turugurt (12,730 ft), both in the Terek range; Barskaun (12,000 ft.), Suka (11,650 ft), and Jauku (14,000 ft) in the Terskei Ala-tau; and Tez (11,800 ft.) and Akbel (12,000 ft), both in the Sary-jas, and Muz-art (12,000 ft) on the east shoulder of Khan-tengri. The snow-line on Terskei Ala-tau runs at 11,500 ft. The summits of the Kulu-tau reach 13,700 to 14,750 ft ; those of the Ak-skiryak 15,000–16,000 ft The Kokshal-tau consists of several parallel ranges, is truly alpine in character and bears large glaciers, which send out arms into U-shaped valleys, behind which the pyramidal mountain peaks tower up. The loftiest range is that to the north, which exceeds 16,000 ft., and the altitude increases generally from west to east as far as the Bedel pass in 78° 30′ E , where the road crosses from Ak-su and Uch-Turfan to the valley of the Naryn and Ferghana

Eastern and Northern Tien-shan.—The system is known here locally as the Barkul Mountains and the Karlyk-tagh Its middle parts are snow-clad, the snow lying down to 12,000 ft. on the north side, while the peaks reach altitudes of 13,000–14,700 ft., but the range is only crossed by passes in the east, at altitudes from 7,805–10,984 ft. Towards the east, the Karlyk-tagh radiates outwards, and decreases in altitude, though it rises again in the rocky Emir-tagh From the Karlyk-tagh a stony desert slopes south to the Chol-tagh. The Chol-tagh marks the northern escarpment, as the Kuruk-tagh, farther south, the southern escarpment, of the great Pe-shan swelling of the desert of Gobi. These two ranges are eastern prolongations, the former of the Khaidyk-tagh and the latter of the Kok-teke Mountains, which enclose on north and south respectively the Yulduz valley and the Lake of Bagh-rash-kul. Thus the Kuruk-tagh are linked, by the Kok-teke, on to the Khalyk-tau of the Khan-tengri group. The Khaidyk-tau, which are crossed by the passes of Tash-againym (7,610 ft) and Kotyl (9,900 ft.), are probably connected with the Trans-Ili

Ala-tau, or its twin parallel range, the Kunghei Ala-tau, in the west. The Narat-tau appear to form a diagonal link between the Khaidyk-tau and the Khalyk-tau and are crossed by passes Sary-tyur (10,800 ft.), Mukhurdai (11,800 ft.), Jambi (11,415 ft) and the Dundeh-keldeh (11,710 ft.).

West of the Barkul range is the gap of Otunkoza by which the Hami and Barkul caravan roads cross into the valley of Dzungaria, and at Urumchi (87° 30′ E), over 200 m. farther west, is a similar gap which facilitates communication between Turfan and Dzungaria Between these gaps stretches the snow-clad range of the Bogdo-ola, average altitude 13,000 ft., and rising to 17,000–18,000 ft. in the double peak of Turpanat-tagh. On the north side of this range the snow-line runs at an altitude of 9,500 ft. At the foot lies the broad, deep valley of Dzungaria (2,500–1,000 ft). On the south the Bogdo-ola is flanked by the nearly parallel range of the Jargoz, a range which carries no perpetual snow. But its altitude does not exceed 10,000 ft, and its steep rocky slopes meet in a sharp, denticulated crest West of the Urumchi gap, the Bogdo-ola is continued in the snow capped double range of the Iren-khabirga (11 500 ft.), which curve north-west and finally, as the Talki Mountains, merge into the Boro-khoro range. They culminate in the peak of Dos-megen-ora (20,000 ft) The Boro-khoro Mountains (average elevation 11,-500 ft) have all the characteristics of a border-ridge The slopes are clothed with Coniferae between 6,000 and 9,000 ft., and the range separates the valley of Kulja (Ili) on the south from the depressions of Zairam-nor (6,820 ft.) and Ebi-nor (670 ft). The passes in the Boro-khoro lie at lower altitudes than is usual in the Tien-shan ranges, namely at 7,000–7,415 ft.

On the north side of the valley of Borotala is the Dzungarian Ala-tau, the northernmost member of the Tien-shan The two principal series of parallel ranges are the northern series (going from east to west) of the Baskan-tau, Sarkan-tau, Karazryk-tau, Bionyn-tau, and Koranyn-tau, at an average elevation of 11,000–13,000 ft., and the southern series of the Urtak-saryk, Bejin-tau and Kok-su, at altitudes of 12,000–14,000 ft

Western and Southern Tien-shan.—On the north side of the Issyk-kul are the parallel twin ranges of the Trans-Ili Ala-tau and Kunghei Ala-tau. The two chains are connected by the lofty trans-verse ridge of Almaty The Trans-Ili Ala-tau swings away to the north-west, and is continued in the echeloned ranges of Kandyk-tau, Kulja-bashi, Khan-tau and the Chu-Ili Mountains of general altitudes between 4,000 ft. and 9,000 ft. These latter ranges separate the Muyunkum desert on the west from the Balkash deserts. The Trans-Ili itself culminates in Mt. Talgar at an altitude of 15,725 ft. The Kunghei Ala-tau rises 8,000 ft above the Issyk-kul and lifts its summits higher than 13,000 ft. The passes across the twin ranges lie at 8,000–11,000 ft (Almaty pass) in the Trans-Ili Ala-tau and at 9,000–10,885 ft. (Kurmenty pass) in the Kunghei Ala-tau. On neither of these ranges are there any true glaciers

The Alexander Mountains terminate over against the town of Aulie-ata (71° 20′ E) at the relatively low altitude of 2,460 ft, though farther east they rise to 13,000–14,000 ft., and even reach 15,350 ft. in Mt. Semenov. On the north their declivities are steep and rugged. They are crossed by passes at 6,550–11,825 ft.

From the middle of the Alexander range (74° E) the Talas-tau breaks away in a west-south-west direction, and from near the western extremity of this latter two parallel ranges, the Chotkal (14,000 ft.) and the Ala-tau, break away in a south-westerly direction, and running parallel to one another and to the river Naryn, terminate at right angles to the middle Syr Darya, after it has made its sweeping turn to the north-west The Talas-tau has an average elevation of 14,000–15,000 ft., its snow-capped summits at 15,750 ft; it is crossed by passes at 8,000–10,650 ft.

Near the west end of the Alexander range, (71° E.) the Kara-tau stretches north-west, between the Syr Darya and the Chu. It consists almost entirely of sedimentary rocks. Its average elevation is 5,000 ft., in places it reaches 7,000–8,000 ft. In the same north-westerly to south-easterly direction are the Ferghana Mountains. The Ferghana Mountains, which are cleft by the Naryn river, have a mean altitude of 10,000 ft, but attain elevations of 12,740 ft (Suyuk) and are crossed by the Terek pass at 9,140 ft.

On the south of the Ferghana valley is the lofty range of the Alai, backed by the parallel range of the Trans-Alai. Both ranges abut at their eastern extremity upon the Pamir plateau, and both extend a long way out into the desert. The Alai is a well-defined ridge with steep slopes, and both it and Terek-tau, which prolongs it towards the Kokshal-tau, are flanked next the Ferghana valley Palaeozoic metamorphic limestones and newer Tertiary series of softer conglomerates and sandstones. The general altitude of both ranges is 16,000–19,000 ft., but the Trans-Alai culminates in peak Kaufmann (23,386 ft.). The Trans-Alai is a true border range, the ascent to it from the Pamir plateau (13,000 ft.) on the south-east being gentle and relatively short, while both it and the Alai tower above the valley of the Alai to an altitude of 11,000 to 14,000 ft This valley is 75 miles in length and is continued towards the south-west by the valley of Karateghin Its breadth varies from three to 12 miles, and it falls from 10,500 ft. (north-east) to 8,200 ft. (south-west). It is drained by the Kyzyl-su, which, under the name of Vakhish, finally enters the Amu Darya Despite frequent avalanches of snow it is an important highway of communication between Bukhara and the Pamirs on the one hand and Kashgar and Ferghana on the other. The principal passes over it into the valley of Ferghana are Taldyk, 11,605 ft with a military road, Jiptyk, 13,605 ft; Saryk-mogal, 14,110 ft; Tenghiz-bai, 12,630 ft; and Kara-kazyk, 14,305 ft The Pamir plateau is reached by the Kyzyl-art pass at 14,015 ft

The Alai Mountains are continued westwards in the radiating ranges of the Karateghin, Zarafshan and Hissar Mountains and the Turkistan range, which reach altitudes of 18,500 ft The Trans-Alai are continued in the Peter the Great range, which culminates in the Sandal group (24,935 ft.). The passes across these ranges are difficult and at 10,000–13,000 ft. The last outlying range of the Tien-shan system in this direction is the Nura-tau. It rises abruptly from the desert and lifts its snowy peaks to altitudes of 15,000–16,000 ft, separating the river Syr Darya from the river Zarafshan The passes over it lie at 10,000–13,000 ft

Routes.—The traditional routes between China, and West Turkistan and Persia have crossed the Tien-shan system at some half a dozen points After traversing the desert of Gobi from Sa-chou to Hami, the northern route crossed over into the Dzungarian valley either by the Otun-koza depression or by the gap at Urumchi, or else it proceeded over the Muz-art pass on the east side of Khan-tengri or over the Bedel pass in the Kokshal-tau and so down into the valley of Kulja. The shortest route, though not the easiest, between Kashgar and East Turkistan, and Ferghana and West Turkistan is over the Terek pass or the pass at the head of the Alai valley, a dangerous route in winter by reason of snow

Journ* (1925) For geology *see:*—Dr. Kurt Leuchs, "Zentralasien," *Handb der Reg. Geol.* (Heidelburg 1916) and E. Argand, *Là Tectonique de l'Asie* (Liége, 1924).

TIENTSIN, a large commercial city in the province of Chihli, China. Estimated population 900,000. It is situated at the junction of the Peiho and the Hun-ho, which is connected by the Grand canal with the Yang-tsze Kiang. The town is built on a vast alluvial plain, which extends from the mountains beyond Peking to the sea, and through which the Peiho runs a circuitous course, making the distance by water from Tientsin to the coast about 70 m, as against 30 m. by railway.

In 1853 Tientsin was besieged by an army of T'aip'ing rebels, who were ultimately forced to retreat. The city and suburbs were occupied by allied forces, English and French, in 1860–62. The city was constituted an open port. There were further riots in 1870. During the period 1874–94 the city prospered under Li Hung-Chang, viceroy of Chihli. The entire city, native and foreign, suffered severely during the Boxer hostilities, June-July

1900. After this the city walls were razed and the municipal services considerably improved. There is a university, several cotton mills and important rice and salt markets. The river front of the Peiho is governed by foreign Powers, who have exacted from time to time various "concessions."

TIEPOLO, GIOVANNI BATTISTA (1692–1769), Italian painter, was born at Venice, and acquired the rudiments of his art from Gregorio Lazzarini, and probably from Piazzetta, though the decisive influence on the formation of his style was the study of Paolo Veronese's sumptuous paintings. He developed an extraordinary facility of brushwork, and proved himself, as a fresco-painter, a colourist of the first order, though this early mastery of technique made him frequently neglect form and composition He decorated many Venetian churches and palaces with ceilings and frescoes full of turbulent movement and rich colour, extending his operations to the near cities of the mainland and to Bergamo (Colleoni Chapel) and Milan (ceiling at Palazzo Clerici). In 1750 he went to Wurzburg to paint the magnificent ceilings and frescoes at the archbishop's palace. From 1753 to 1761 he worked again at Venice and in the cities of north-east Italy, until he was summoned to Madrid by Charles III to paint some frescoes for the royal palace He died at Madrid in 1769.

Tiepolo's altarpieces and easel pictures show more clearly even than his frescoes how deeply he was imbued with the spirit of Paolo Veronese, for in these smaller works he paid more attention to the balance of composition, whilst retaining the luminosity of his colour harmonies The majority of his works, both in fresco and in oils, are to be found in Venice in the churches of S. Aloise, SS. Apostoli, Gesuati, the Academy, the Palazzi Labia and Quirini-Stampalia, and the Doge's Palace

See Henry de Chennevières, *Les Tiepolo* (1898); and Pompeo Molmenti, *G. B. Tiepolo* (Milan 1910).

TIERCERON, in mediaeval architecture, an intermediate vaulting rib running from the spring of the vault to the ridge, at an angle between the cross rib and the diagonal or groin rib, or, in cross vaults, between the diagonal rib and the wall rib. Tiercerons came into use in the early Decorated period of English Gothic and Exeter cathedral (1308–67) shows the delicate beauty and lightness that the use of tiercerons gives. *See* GOTHIC ARCHITECTURE; VAULT.

TIERRA DEL FUEGO, an archipelago lying between 52° 27′ and 55° 59′ S lat. and 63° 43′ and 74° 44′ W. long. at the southern extremity of South America, from which it is separated by Magellan strait. At the First Narrows and at other points the strait is scarcely a mile wide. In shape the main island is a triangle with its base in the Beagle channel. The total area is about 28,000 sq m. of which 19,500 sq m belong to Chile and 8,500 to Argentina Argentina holds that part of the main island which lies east of the meridian of Cape Espiritu Santo (68° 36′ 38″ W.) and Chile holds all the western part of the main island and other numerous islands to the west and to the south of Beagle channel. The Argentine side is known as the Gobernacion of Tierra del Fuego (including Staten island) and the Chilean forms part of the Territory of Magellanes. Although in the '80s of the past century extensive deposits of alluvial gold were discovered, their exploitation was not generally successful and farms took the place of mines. The Argentina census of 1914 reported 64 haciendas covering 4,830 sq.m. with about 800,000 sheep, 7,000 cattle and 5,000 horses on the Argentina side. The sheep industry is particularly profitable and growing rapidly.

Physical Features.—The greater part of the main island is formed by the continuation of the Tertiary beds of the Patagonian table-land cut by the transversal depression of Magellan strait and by the lowland extending from Useless bay in the west to San Sebastian bay on the east and analogous to the transverse valleys of the Patagonian table-land. North of the lowland is an undulating table-land with an average height of 400 ft, intersected by numerous *arroyos* with little water and with good sheep pasture. In the west and south-west the general character of the main island changes; the ends of the Tertiary beds are raised—small hills and Mesozoic rocks appear, forming broken ridges east of the main range of the Andes. In this region appears the Antarctic forest. Lake Solier and Lake Fagnans receive the water from these mountains and hills. To the south of the lake rises the south-eastern prolongation of the Andes with ridges at a uniform height of 3,500 ft. in which predominate crystalline schists. Some peaks of Tertiary granite break the uniformity, such as Mt. Sarmiento (7,540 ft), Mt Darwin (about 7,500 ft) and Mt. Ulewaia (4,500 ft.), called Olivaia on some maps

The section of the archipelago south of Beagle channel includes the islands of Hoste, Navarin, Gordon, Londonderry, Stewart Wollaston and numerous islets, disposed in triangular form with the base on Beagle channel and the apex at Cape Horn. Important explorations in this region were conducted by the French Mission de Cap Horn (1882–83). The most recent explorations on the western part of the main island of Tierra del Fuego immediately south of Beagle channel (in the Fiords de Agostini. Admiral Martinez and others) were carried out by Alberto M de Agostini in 1913–14 The western group of islands includes Clarence island (formerly believed to be a single island but now known to be divided by a channel into two sections known as Santa Ives and Desolation islands) and numerous small islands and rocks.

Climate.—At Ushuaia ten years' meteorological observations have shown a mean annual temperature of 42 8° F, with a winter mean of 34 7°, a summer mean of 50 2°, and an average yearly precipitation of 24 8 inches. Of all winds, 80% are westerly and a great difference in precipitation between the windward and leeward sides of the islands has been noted not only in the western part but also on Staten and Observatory islands. Precipitation on all windward slopes is almost continuous, producing dense forests on the lower slopes, where it falls as rain, and snow and ice-fields on the upper slopes.

Inhabitants.—To the three geographical divisions correspond three well-marked ethnical groups—the Onas on the main island south of the Grande river, the Yagans (Yahgans) on the southern islands and the Alakalups on the western The origin of the Onas, like that of the other groups, is obscure Undoubtedly among them are many that resemble some Patagonian type, but they seem to be not the same as the Tehuelche type and may pertain to one of the earlier Patagonian races Their language is closely allied to that called Old Tehuelche, it is a hard guttural, slow-spoken speech, not at all resembling the soft, rapidly-spoken language of the Yahgans, which has many points of similarity with that of the Alakalups The isolation of the Onas is peculiarly marked as they are insular people who do not use boats The Yahgans live under conditions of extraordinary rigour. In order to obtain food, they venture naked with small canoes into the tremendous seas Their life is a constant battle with starvation and a severe climate and their number is being rapidly depleted They have no higher social unit than the family. The missionaries, who have reduced their language to writing, assert that it contains no less than 30,000 words, although the numerals stop at five, but it appears that a large number of words included in this total are compounds. Comparatively little is known of the Alakalups.

Discovery and Exploration.—Tierra del Fuego was discovered by Fernando de Magellan in 1520 when he sailed through the strait named after him and called this region "Land of Fire." In 1578 Sir Francis Drake first sighted the point which in 1616 was named Cape Hoorn (Anglicized Horn) by the Dutch navigators Jacob Lemaire and William Cornelis Schoote (1615–17) In 1619 the brothers Garcia and Gonzalo de Nodal first circumnavigated the archipelago No systematic exploration was attempted until the British Admiralty undertook a thorough survey of the whole group by Philip Parker King (1762–1828) and Robert Fitzroy (1831–36). The latter expedition (Voyage of the "Beagle") was accompanied by Charles Darwin, then a young man. To these admirable surveys is due most of the present geographical terminology of the archipelago, and although supplemented by later surveys in many parts by the Chilean navy they still form the basis and, to a large extent furnish the detail, for most hydrographic charts of the region.

TIFFANY, CHARLES LEWIS (1812–1902), American jeweller, was born in Killingly (Conn), on Feb. 15, 1812 He removed to New York city in 1837, and with John B. Young opened a fancy goods store In 1847 the firm began to manufacture gold jewellery. It became Tiffany, Young and Ellis in 1841 and was reorganized as Tiffany & Co in 1853.

At the beginning of the Civil War, Tiffany turned most of his capital to the manufacture of swords, medals and similar war material. In 1868 the company was incorporated and branches were established at London and at Geneva Tiffany made a specialty of importing historic gems, jewellery and art works, and in 1887 bought some of the crown jewels of France. He was made a chevalier of the Legion of Honour in 1878. He died in New York on Feb. 18, 1902

TIFFANY, LOUIS COMFORT (1848–), American artist, son of Charles L Tiffany, was born in New York city on Feb. 18, 1848. He was a pupil of George Inness and of Samuel Coleman, New York, and of Léon Bailly, Paris. He became a member of the Society of American Artists (1877), of the National Academy of Design (1880), of the American Water Color Society, and of the Société Nationale des Beaux Arts, Paris. In 1900 he was made a chevalier of the Legion of Honour in Paris, and in America has received a number of medals. He travelled extensively in Europe, and painted in oil and water-colour, but eventually devoted himself to decorative glass work. He became president and art director of the Tiffany Glass and Decorating Company, and produced a "Favrile" glass, of unusual beauty of colour. In 1918 he founded the Louis Comfort Tiffany Foundation for art students at Oyster Bay (N Y), deeding his country home, Lawreton Hall, with over 60ac. of land, his art collection, and a maintenance fund of $1,000,000.

TIFFIN, a city of northern Ohio, U.S.A., the county seat of Seneca county; on the Sandusky river, 40 m. S.S.E. of Toledo. It is served by the Baltimore and Ohio, the Big Four, the Pennsylvania and electric railways. Pop. 14,375 in 1920 (94% native white); 1928 local estimate 16,800. Tiffin was settled in 1817 and was named after the first governor of the State. It was incorporated as a town in 1835 and as a city in 1850, when the village of Fort Ball, across the Sandusky, was united with it.

TIFLIS, the capital of the Georgian S.S R., and the administrative centre of the Transcaucasian S.F S.R, situated on both banks of the Kura river, and on the railway linking the Black Sea and the Caspian, in 41° 41′ N., 44° 48′ E. Pop. (1926) 282,918. Shut in by hills (1,500 to 2,400 ft.), it is sheltered in winter, but hot and stifling in summer, its average temperature ranging between 34·7° F, in winter and 73·4° F in summer. It manufactures bricks, tobacco, vegetable oils, soap, cognac, leather goods, furniture, and has a saw-milling industry. In 1926–7, the Zemo-Avchal hydro electric station, with a capacity of 13,000 kilowatts, was opened. There are municipal electricity, water, canal and tramway services, and the town is well built. The Sion cathedral traces its origin to the 5th century; other churches date from the 14th and 15th centuries, and the Armenian cathedral of Van from 1480. There are numerous educational institutions. The town is at the southern extremity of the Georgian Military road, which links it through the Dariel Gorge with Vladikavkaz. The Oriental markets and bazaars of the native quarter, where Persians, Kirghiz, Tatars and peoples from the east congregate, display the work of Georgian silversmiths, gunsmiths and sword-makers, carpets, dried fruits and silken goods are important items, and there is much exchange of Persian and Russian wares.

The Georgian annals put the foundation of Tiflis back to A.D. 379. (*See* GEORGIA, *History*) In the latter half of the 5th century the chieftain of Georgia, Wakhtang Gurgaslan, transferred his capital from Mtskhet to the warm springs of Tiflis, where he erected several churches and a fort. In 570 the Persians took the place and made it the residence of their rulers, but retained it only for ten years. Tiflis suffered successive plunderings and devastations at the hands of the Greeks in 626, of one of the commanders of the Caliph Omar in 731, of the Khazars in 828, and of the Arabs in 851. The Georgians, however, always managed to return to it and to keep it in their permanent possession. In the course of the succeeding centuries Tiflis fell repeatedly into Persian hands; and it was plundered by the Mongol conqueror Tamerlane towards the end of the 14th century. Afterwards the Turks seized it several times, and towards the end of the 17th century the Lesghians attacked it. In 1795, when the shah of Persia plundered Tiflis, Russia sent troops to its protection, and the Russian occupation became permanent in 1799. One of the fullest accounts of Tiflis is contained in Brosset's edition of the *Description géographique de la Géorgie* (St. Petersburg, 1842), by the illegitimate son of Wakhtang VI, king of Karthli (*i.e*, Georgia), who became a pensioner of Peter the Great

TIGELLINUS, TOFONIUS, minister and favourite of the emperor Nero, was a native of Agrigentum, possibly of Greek descent. During the reign of Caligula he was banished (A.D. 39) for adultery with the emperor's sisters, but recalled by Claudius (41). Having inherited a fortune, he bought land in Apulia and Calabria and devoted himself to breeding race-horses In this manner he gained the favour of Nero In 62 he was promoted to the prefecture of the praetorian guards. The great fire of 64 broke out afresh in his gardens, and he was suspected of being concerned with it. In 65, during the investigation into the abortive conspiracy of Piso, he and Poppaea formed a kind of imperial privy council. In 67 he accompanied Nero on his tour in Greece He deserted Nero at the last, and took the praetorians with him Under Galba he was obliged to give up his command, but managed to save his life. Otho on his accession (69) determined to remove him. While in the baths at Sinuessa, Tigellinus received the news that he must die, and, having failed to gain a respite, cut his throat.

See Tacitus, *Annals*, xiv, xv, xvi; *Hist* i. 72, Dio Cassius lix. 23, lxii. 13, 15, 27, lxiii. 12, 21, lxiv 3; Suetonius, *Galba*, 15; Plutarch, *Galba*, *Otho;* ancient authorities quoted by Mayor on Juvenal, i. 155; B. W Henderson, *Life and Principate of the Emperor Nero* (1903).

TIGER (*Felis tigris*), an animal only rivalled by the lion in size, strength and ferocity among the cat-like beasts of prey (*see* CARNIVORA), the difference between the two lying mainly in the skin and its coverings A tiger's skull may, however, always be distinguished from that of a lion by the circumstance that the nasal bones extend higher on the forehead than the maxillae, instead of stopping on nearly the same line Although examples of both species present considerable variations in size, the length of the largest Bengal tiger may exceed that of any lion. Ten feet from the tip of the nose to the end of the tail is no unusual length for a large male tiger. The female is somewhat smaller, and has a lighter and narrower head. The tiger has no mane, but in old males the hair on the cheeks is rather long and spreading. The ground-colour of the upper and outer parts of the head, body, limbs and tail, is bright rufous fawn; and these parts are beautifully marked with transverse stripes of a dark, almost black colour. The markings vary much in different individuals, and even on the two sides of the same individual. The under-parts of the body, the inside of the limbs, the cheeks and a large spot over each eye are nearly white. The tigers which inhabit hotter regions, as Bengal and the south Asiatic islands, have shorter and smoother hair, and are more richly coloured and distinctly striped than those of northern China and Siberia, in which the fur is longer, softer and lighter-coloured. Black and white phases have been recorded, but they are rare. The tiger is exclusively Asiatic, but has a wide range in that continent, having been found in almost all suitable localities south of a line drawn from the River

Euphrates, passing along the southern shores of the Caspian and Sea of Aral by Lake Baikal to the Sea of Okhotsk. Its most northern range is the territory of the Amur, its most southern the islands of Sumatra, Java and Bali. Westward it reaches to Turkish Georgia and eastward to the island of Sakhalin. It is absent, however, from the great elevated plateau of Central Asia, nor does it inhabit Ceylon, Borneo or the other islands of the Indo-Malay archipelago, except those named.

The principal food of the tiger in India is cattle, deer, wild hog and pea-fowl, and occasionally human beings The regular "man-eater" is generally an old tiger whose vigour is past, and whose teeth are worn and defective, it takes up its abode in the neighbourhood of a village, the population of which it finds an easier prey than wild animals. Though chiefly affecting grassy plains or swamps, tigers are also found in forests, and seem to be fond of haunting the neighbourhood of old ruins. As a rule, they do not climb trees, but when pressed by fear, as during an inundation, they have been known to do so. They take to the water readily and are good swimmers.

BY COURTESY OF THE N Y ZOOLOGICAL SOCIETY

THE TIGER (FELIS TIGRIS), THE MOST POWERFUL OF THE CAT FAMILY

The tigress gives birth to from two to six cubs, but three is the common number. She is an affectionate mother, and generally guards and trains her young with watchful solicitude They remain with her until nearly full-grown, or about the second year, when they are able to kill for themselves Whilst they remain with her she defends them with great courage and energy, and when robbed of them is terrible in her rage, but she has been known to desert them when pressed, and even to eat them when starved. As soon as they begin to require other food than her milk, she kills for them, teaching them to do so for themselves by practising on small animals. The tiger and the lion occasionally hybridize.

See Sir J Fayrer, *Royal Tiger of Bengal* (1875); F. W Champion, *With a Camera in Tiger Land* (1927)

TIGER-CAT, typically *Felis tigrina*, an American wild cat ranging from Mexico, on the east of the Andes, to Paraguay and the central forest region of Argentina. It measures something over 30in., including the tail. The fur is grizzly grey, with black spots. The name is also applied to the ocelot (*q.v.*).

TIGER-FLOWER, botanically *Tigridia*, a genus of bulbous plants (family Iridaceae), natives of Mexico, Central America, Peru and Chile. They have long narrow plicately-veined leaves springing from the bulb and a stem bearing two or three scattered smaller leaves and above a few flowers emerging from a spathe. The flowers are spotted (whence the name tiger-flower or tiger-iris) and have free segments springing from a tube; the three large broad outer segments are concavely spreading, the three inner are much smaller and more erect. *T. Pavonia* (flower of Tigris or tiger-flower) has large flowers with a golden orange, white or yellow ground colour.

TIGHINA (Turkish, *Bender*, the Gate, from the fortress erected by Suleiman the Magnificent in 1558, but demolished in 1897; Russian, *Bendery*), a town of Bessarabia, Rumania, capital of department of same name, on the Dniester. Pop. (1924) about 42,000, including many Jews and Ukrainians. It is connected by rail with Kishinev (37 m.) and southward via Basarabiasia with Cetatea Alba and Galatz, and a railway also runs over the river into Russia to Tiraspol and Odessa. Tighina possesses a tobacco factory, candle-works and brick-kilns and a saw-mill. Timber is floated down the Dniester, and the town is a centre for products of the surrounding districts. In the 12th century it was a Genoese trading centre, and has been held in turn by Tatars, Moldavians, Turks, Russians and Rumanians. The forces of Charles XII. camped here 1709–13.

TIGLATH-PILESER (Ass. *Tukulti-pal-E-sarra*, "my confidence is the son of E-sarra," *i.e.*, the god In-Aristi), the name of several Assyrian kings. Their numbering is not certain.

Tiglath-Pileser I., the son of Assur-ris-isi, ascended the throne *c.* 1120 B C, and was one of the greatest of Assyrian conquerors. His first campaign was against the Moschi who had occupied certain Assyrian districts on the Upper Euphrates; then he overran Commagene and eastern Cappadocia, and drove the Hittites from the Assyrian province of Subarti north-east of Malatia. In a subsequent campaign the Assyrian forces penetrated into the Kurdish mountains south of Lake Van and then turned westward, Malatia submitting to the invader In his fifth year Tiglath-Pileser attacked Comana in Cappadocia, and placed a record of his victories engraved on copper plates in a fortress he built to secure his Cilician conquests. The Aramaeans of north Syria were the next to be attacked, and he thrice made his way as far as the sources of the Tigris. The command of the high road to the Mediterranean was secured by the possession of the Hittite town of Pethor at the junction of the Euphrates and Sajur, and at Arvad he received presents, including a crocodile, from the Egyptian king, and, embarking in a ship, killed a dolphin in the sea. He was passionately fond of the chase and was also a great builder, the restoration of the temple of Assur and Hadad at Assur (*q v.*) being one of his works.

Tiglath-Pileser II. or III, son of Hadad-nirari II, appears to have reigned from about 950 to 930 B C, but nothing is known about him.

Tiglath-Pileser III or IV, was a successful general who usurped the Assyrian throne on the 13th of Iyyar 745 B C., after the fall of the older dynasty, and changed his name of Pulu (Pul) to that of the famous conqueror of earlier times In Babylonia, however, he continued to be known as Pulu. He was a man of great ability, both military and administrative, and initiated a new system of policy in Assyria which he aimed at making the head of a centralized empire, bound together by a bureaucracy who derived their power from the king The empire was supported by a standing army and an elaborate system of finance. The first task of Tiglath-Pileser was to reduce the Aramaean tribes to order, and so win the gratitude of the Babylonian priests Then he struck terror into the wild tribes on the eastern frontiers of the kingdom by a campaign which extended into the remotest parts of Media Next came the defeat of a northern coalition headed by Sar-duris of Ararat, no fewer than 72,950 of the enemy being captured along with the city of Arpad, where the Assyrian king received the homage of various Syrian princes. Arpad revolted soon afterwards, but after a siege was taken in 740 B C The following year Azariah of Judah appears among the enemies of Tiglath-Pileser, who had overthrown his Hamathite allies and annexed the nineteen districts of Hamath. The conquered populations were now transported to distant parts of the empire. In 737 B C. Tiglath-Pileser again marched into Media, and in 735 he invaded Ararat and wasted the country round the capital Van to a distance of 450 miles. In 734 B.C he was called to the help of Yahu-khazi (Ahaz) of Judah, who had been attacked by Pekah of Israel and Rezon (Rasun) of Damascus. Rezon, defeated in battle, fled to his capital which was at once invested by the Assyrians, while with another portion of his army Tiglath-Pileser ravaged Syria and overran the kingdom of Samaria Ammon, Moab, Edom and the queen of Sheba sent tribute, and Teima in northern Arabia was captured by the Assyrian troops In 732 B C Damascus fell; Rezon was put to death, and an Assyrian satrap appointed in his stead. Tyre also was made tributary The next year Tiglath-Pileser entered Babylonia, but it was not until 729 B C. that the Chaldaean prince Ukin-zer (Chinzirus) was driven from Babylon and Tiglath-Pileser acknowledged as its legitimate ruler. In the early part of Tebet 727 B C. he died, after having built two palaces, one at Nineveh, the other at Calah

See P. Rost, *Die Keilschrifttexte Tiglat-Pilesers III.* (1893), also Babylonia and Assyria, § v *History* ("Second Assyrian Empire"), and authorities quoted in § viii. *Chronology*

TIGRANES or **DIKRAN,** king of Armenia (*c.* 140–55 B.C.). He was the son or nephew of Artavasdes of Armenia, and a member of the dynasty founded by Artaxias, a general of Antiochus III. (*See* Seleucid Dynasty.) He was given to Mithradates II. of Parthia as a hostage, and purchased his freedom by ceding 70 valleys bordering on Media.

Tigranes ascended the throne in 95 or 94 B C. (Plut. *Luc.* 21), and immediately began to enlarge his kingdom He deposed Artanes, king of Sophene, and entered into alliance with Mithradates VI Eupator of Pontus, whose daughter Cleopatra he married. In 93 he invaded Cappadocia in the interest of Mithradates, but was driven back by Sulla in 92. During his first war with Rome, Mithradates was supported by Tigranes, although he abstained from interfering openly. But he meanwhile began war with the Parthians, whose empire was weakened after the death of Mithradates II. (about 88) by internal dissensions and invasions of the Scythians. Tigranes reconquered the valleys which he had ceded, and laid waste a great part of Media, the kings of Atropatene, Gordyene (now Bohtan), Adiabene (Assyria) and Osroene (Edessa) became his vassals, who attended him like slaves whereever he went; he also annexed northern Mesopotamia In 83 he invaded Syria, defeated the last successors of Seleucus and occupied Cilicia. In the war between Mithradates and Sulla he did not interfere, but after the death of Sulla (78) he occupied Cappadocia again and expelled King Ariobarzanes I, the vassal of the Romans. During the next years he had a war in Syria, against Cleopatra Selene, and in Cilicia, where he destroyed the Greek town of Soli. Tigranes now had become "king of kings" and the mightiest monarch of Asia So he built a new royal city, Tigranocerta, on the borders of Armenia and Mesopotamia, between Mt Masius and the Tigris, where he accumulated all his wealth and to which he transplanted the inhabitants of twelve Greek towns of Cappadocia, Cilicia and Syria (for the situation, which is much disputed, *cf* Tac *Ann* xiv 24, xv 5, ed Furneaux) He also transplanted many Arabic tribes into Mesopotamia But the Romans could not tolerate encroachment upon their sphere of power, and in 69 Lucullus invaded Armenia Tigranes was beaten at Tigranocerta on Oct 6, 69, and again near Artaxata in September 68. The recall of Lucullus gave some respite to the two kings, who even invaded Asia Minor again But meanwhile a son of Tigranes and Cleopatra, called Tigranes, like his father, rebelled against him (as the old man had already killed two of his sons, he had reason enough to be afraid for his life) and found refuge with the Parthian king Phraates III, who sent him back with an army The old king now gave up all hope of resistance, he put a price on the head of Mithradates, and when Pompey advanced into Armenia and united with the younger Tigranes, he surrendered (66 B C). Pompey now changed his policy, he received the old Tigranes graciously and gave him back his diadem, while he treated the son very coolly and soon made him prisoner The younger Tigranes was led in triumph into Rome, where he found his death when he tried to escape from his confinement by the intrigues of P. Clodius in 58 The father after his defeat ruled about ten years longer over Armenia, as vassal of the Romans He died about 56, and was succeeded by his son Artavasdes (*See* also MITHRADATES)

TIGRÉ, a northern province of Abyssinia; one of the four former principal divisions of the country Tigré contains the towns of Axum (*q v*), capital of the ancient Ethiopic Empire, and Adua (Adowa, *q v.*). (*See* ABYSSINIA)

Tigriña, the dialect spoken in Tigré and Lasta, is nearer the ancient Gïz than is Amharic, the official and more widely diffused language of Abyssinia

See J. Schreiber, *Manuel de la langue tigrai* (Vienna, 1887–93); and L. de Vito, *Grammatica della lingua tigrigna* (Rome, 1895).

TIGRIS, the more eastern of the two rivers of Mesopotamia It rises from two principal sources. The eastern branch rises from several streams to the south and west of Lake Van. The western branch rises about ten miles south of Lake Geuljik. The upper waters of the Tigris therefore lie on the southern slopes of the Taurus the northern slopes of which are part of the basin of the Euphrates. The Tigris in its lower course seems to be particularly unstable Although there is no evidence of any great change in the upper waters, from Kut al Amara onwards the bed of the river has shown considerable variations At the beginning of the second millennium B C. the river appears to have been flowing along the Shatt al Hai; indeed the position of Lagash makes it almost certain that this was its normal course in Sumerian times. In Sassanid times it followed its present easterly course; during Arab times, however, it was apparently flowing along the Shatt al Hai There are no ancient remains on the Tigris therefore below Kut al Amara, and owing to the changeable nature of the stream even few modern villages In the alluvial area the Tigris lies lower than the Euphrates as far as the Shatt al Hai, and therefore in ancient times received the tailings of the canals, but did not supply water except locally for irrigation. It appears not to have deposited its silt as much as the Euphrates, probably due to the lack of suitable terrain for the formation of fresh water lakes, which are usually a silting ground for river deposits Since its abandonment of the old channel the Tigris has probably contributed very considerably to the formation of new land at the head of the gulf. The upper drainage area also seems to have altered to a slight extent The Arab geographers suggest that at one time at least part of the waters of the Khabur, a tributary of the Euphrates, flowed into the Tigris by a channel which was navigable when in flood As late as 1832 Ormsby reported a stream from Jabal Sinjar which joined the Euphrates near Sharqat This stream still appears to exist, but it no longer empties itself into the Tigris and in view of the waywardness of the rivers of Mesopotamia it is possible that Ormsby's observation was made at an unusual period

Topography.—The Western Tigris, on whose banks lies the important town of Diarbekr flows east along the southern slopes of the Taurus and receives a number of tributaries of small size The two main branches join at Til, from which point it runs in a south-easterly direction It continues to receive a number of small tributary streams, mostly on the left bank From the neighbourhood of Mosul to the confluence of the Greater Zab there lies a fertile triangle of land between the hills and the river Nineveh lay on the left bank opposite Mosul A little lower down the stream was the city of Kalakh At this point two great barrages were erected in ancient times, which still effectively block the river for navigation From a little above the confluence of the Greater Zab down to Tekrit the river flows through an uninhabited desert, the only important town being Kalaat Sharqat, the ancient Assur, which at present forms the railhead of the southern part of the Baghdad railway. About thirty miles below Sharqat the Lesser Zab joins the Tigris. From Tekrit, a city founded during the Persian domination, downwards, signs of ancient irrigation begin, although the alluvial plain is not entered till Samarra is reached Below Samarra as far as Kut al Amara, a distance of about 200 miles, there was in ancient times a canal which served to straighten the course of the stream The two principal tributaries in this region, the Adhem and the Diala, were also canalized, the Adhem reaching the main stream just below Samarra, the Diala below Baghdad. Close to the mouth of the Adhem are the ruins of an ancient city probably to be identified with Xenophon's Opis Near this point the river makes a great bend and flows south to Baghdad (*q v.*) at which point the Tigris and the Euphrates are only about 35 miles apart In ancient times the two rivers ran close to one another and there are traces of numerous old irrigation canals connecting them Below Baghdad lie the ruins of ancient Ctesiphon, on the left bank; opposite Seleucia on the other bank Kut al Amara marks the point where the Shatt al Hai leaves the present main stream. Below this point owing to the change in the course of the stream there are no ancient remains along the Tigris. The modern towns are Ali al Gharbi, Ali esh Sharki Amara, Qalaat Saleh and Kurna, below which point the two rivers unite to form the Shatt al Arab.

Navigation.—Although before the World War a launch navigated the river between Baghdad and Samarra (about 90 miles), and in 1838 a steamer went to within 28 miles of Mosul the upper Tigris is only navigable for native rafts. These rafts which may be as much as 35 tons burden are made of timber supported by inflated skins. During flood they cover the 275 miles between Baghdad and Mosul in three or four days. At their destination the wood finds a ready market in this treeless country, and the

skins are carried ba again on the backs of asses No upstream traffic is carried on. he river flows over a bed of clay, sand or conglomerate, and i ull of obstructions Opinion has however been expressed that hese obstructions and the ancient barrages at Sharqat were clear away, navigation to Mosul would be possible. In the lower pa of the river there are bridges of boats at Baghdad, Gerara, KuKut al Amara and Kale Sale Between Baghdad and Kale S the Tigris is navigable all through the year by vessels draw up to five feet of water Below this point the river is in a l condition, largely owing to the barrages built by native cultivars, but great efforts have been made to restore the channel. A ow water it is generally estimated that only three feet of wat is available The low water period is reckoned from July to ovember, and high water from December to June, but the rir is extremely liable to sudden floods.

The statistical detailso far as at present recorded are as follows. From Baghdad Kut the distance by river is 216 miles, the distance by land bein103 miles. At Baghdad the river is 114 feet above sea level, at ut it is 57 feet, the fall in the river surface being 1 in 20,00 The width of the river is about a quarter of a mile, its deh at high water 26 feet, and at low 4½ The discharge in flood 5,500 cubic metres a second, dropping to as low as 300 cubic mets at low water The velocity in flood is a little under four milean hour, dropping at low water 1¼ At Kut the Shatt al Hai dcharges about 1,000 cubic metres at high flood, but is dry at lw water Between Kut and Kut al Amara the river distance is 3 miles, and by land 119 The mean level at Amara is 28 feet, tl drop between the two points being therefore about 19 feet, thgradient of the river level is 1 in 35,000 The average width f the river in this reach, which is singularly free from any obacles for navigation, is about 365 yards, while the depth is 25 et in flood and about 6 ft 6 in at low water, with a respective locity of about the same as in the upper reach The discharge low water is similar but at high water about 1,000 cubic mets less at the head of the reach, owing however to branches at he lower end of the reach the discharge at high water only reahes about 2,500 cubic metres per second

Between Amara and Kurnathe river is affected by various channels which drain off muchof the water. At Amara on the left bank the Chala, with a bedbout 6 feet lower than the main stream, discharges about 1,000 cbic metres a second at high water falling to rather more than a tenh of that amount at low Below this point first the Majar Kebirand then the Machera draw off about the same amount Considrable changes take place theretore in the size of the stream betveen Amara and Kurna, at which point the level is ten feet above ea level The average width of the Tigris at this reach is a ittle under 200 yards, with a depth of 13 feet in flood and 6 ft 6 in at low water with a discharge of only 1,250 cubic metres per econd and 150 at high water and low water respectively. Belov Kale Sale although the depth is the same the average width is nly 65 yards. Below Ezra's Tomb some of the lost waters retun to the river from swamps and the stream becomes once morenearly 200 yards broad The two rivers meet at Karmat Ali at which point the Tigris, full of dark marshy water, is over thirty fet deep and over 400 yards broad

It will be seen from these dtails that the river presents great difficulties for navigation In flod time it is liable to overrun its banks and convert the whole rgion into a vast lake In addition to river steamers two typesof native boats are used. a large coracle or *Quffeh* and river boat, *Safineh*, capable of carrying a cargo of as much as 100 tons The coracles can only go downstream but the river boats are pled or towed upstream and are sailed or rowed with the current.

See Sir W. Willcocks, *The Irrigation of Mesopotamia* (1911), *Memorandum respecting the Navigation of the Tigris and Euphrates* (1913); *Colonial Office Reports* (annually). For ancient sites *see* S. Langdon, *Cambridge Ancient History* (1923) (Bibliography)

(L H. D B)

TILAK, BAL GANGADHAR (1856–1920), Indian nationalist leader, a Chitpavan Brahmin, was born at Ratnagiri July 23, 1856 At an early age he took the lead in providing education in Poona under Indian direction. In 1890 he was proprietor and editor of two weekly papers, *Mahratta*, printed in English, and *Kesari* (*Lion*), printed in Mahratti, which organs he used for anti-Government propaganda His violent condemnation in 1897 of the plague prevention regulations resulted in his being convicted for sedition and sentenced to 18 months' imprisonment For a similar offence he was sentenced in 1908 to six years' transportation, subsequently commuted to simple imprisonment After his release he took an active part in the home-rule campaign, and secured for his party the control of the National Congress He died in Bombay on Aug 1, 1920 His formative part in the cult of Indian unrest is shown in the report of the Rowlatt sedition committee (1918) His speeches are collected in *Lokamanaya B. G. Tilak* (2nd ed Madras, 1920).

TILBURG, a town in the province of north Brabant, Holland, and a junction station 13½ m E by S of Breda by rail Pop. (1927), 71,327 Tilburg has risen into importance since the separation of Belgium from Holland as one of the chief industrial centres of the south

TILBURY DOCKS, on the north shore of the Thames, in Essex, England They lie opposite Gravesend 25 m below London bridge, and about the same distance from the Nore, being thus within the Port of London They were constructed in 1886 There is extensive warehousing as well as accommodation for passengers, as the largest passenger steamers trading with the Port of London lie here Railway communication is provided by the L M S There is direct connection for goods traffic with all the northern lines The rapid development of the Port of London has necessitated many changes and extensions since the docks were built Changes began in 1917 when the Port of London authority extended the main dock 1,450 feet In 1926 a new entrance was planned with a length of 1,000 ft, width 110 ft, depth 45½ feet The site is 400 yd above Tilbury Ness New dry docks are also being built (1928) east of the old dry docks Provision is made for the landing of river cargo west of the entrance to the tidal basin and also for better passenger facilities

TILDEN, SAMUEL JONES (1814–1886), American statesman, was born at New Lebanon, N Y, on Feb 9, 1814 In 1834 he entered Yale university, but soon withdrew on account of ill health, and later studied in the College of the City of New York He was admitted to the bar in 1841, and rose rapidly to the front rank In the financial troubles between 1850 and 1860 it is said that more than half the railways north of the Ohio river and between the Hudson and the Missouri rivers were at some time his clients In spite of his activity at the bar, Tilden maintained an interest in politics, serving in the State assembly in 1846 and in the State Constitutional Conventions of 1846 and 1867 In 1848, largely on account of his personal attachment to Martin Van Buren he participated in the revolt of the "Barnburner" or free-soil faction of the New York Democrats, and in 1855 was the candidate of the "softshell" or anti-slavery faction for attorney general of the State During the Civil War, although he opposed several of the war measures of President Lincoln's Administration, he gave the Union cause his heartiest support

In 1866 Tilden became chairman of the Democratic State committee, and soon came into conflict with the notorious "Tweed ring" of New York city As the "ring" could be destroyed only by removing the corrupt judges who were its tools, Tilden, after entering the assembly in 1872 to promote the cause of reform, took a leading part in their impeachment By analysing the bank accounts of certain members of the "ring," he obtained legal proof of the principle on which the spoils had been divided His fame as a reformer brought him to the governor's chair in 1874, and he at once gave his attention to breaking up the "canal ring," made up of members of both parties who had been systematically robbing the State through the maladministration of its canals

In 1876 the Democrats nominated him for the Presidency, the Republicans nominating Rutherford B Hayes of Ohio The result was the disputed election of 1876, when two sets of returns were sent to Washington from the States of Florida, Louisiana, South Carolina and Oregon As the Federal Constitution contained no provision for settling a dispute of this kind the two houses of Congress agreed to the appointment of an extra-con-

stitutional body, the "Electoral Commission" (*q.v.*), which decided all the contests in favour of the Republican candidates. Tilden counselled his followers to abide quietly by the result. The remainder of his life was spent in retirement at his country home, Greystone, near Yonkers, N.Y., where he died Aug. 4, 1886. Of his fortune (estimated at $5,000,000) approximately $4,000,000 was bequeathed for the establishment and maintenance of "a free public library and reading-room in the City of New York"; but, as the will was successfully contested by relatives, only about $2,000,000 of the bequest was applied to its original purpose; in 1895 the Tilden Trust was combined with the Astor and Lenox libraries to form the New York Public library.

See *Writings and Speeches of Samuel J. Tilden* (1885) and *Letters and Literary Memorials of Samuel J Tilden* (1908), both edited by John Bigelow, also Bigelow's *Life of Samuel J. Tilden* (1895); and P. L. Haworth, *The Hayes-Tilden Election* (1927).

TILDEN, SIR WILLIAM AUGUSTUS (1842–1926), British chemist, was born on Aug 15, 1842, at St. Pancras, London; he was first apprenticed to a pharmacist, and in 1863 became demonstrator at the Pharmaceutical Society's school. In 1872 he was appointed senior science master at Clifton college; then, in 1880, he became first professor of chemistry at Manor college, Birmingham, and in the same year was elected to the Royal Society; in 1894 he transferred to the chair at the Royal College of Science, London, and there he remained until his retirement in 1919. He died on Dec. 11, 1926.

Tilden's first contribution to chemical research was in connection with the per-iodides of organic bases (1865), and for some years he studied the alkaloids (*q.v.*) and other substances obtained from plants. In 1874 he examined, together with W. A. Shenstone, the properties of aqua regia and nitrosyl chloride, and whilst investigating the action of the latter on various organic compounds he discovered the nitroso-chloride of pinene. This discovery eventually led to a valuable method for the identification of terpenes (*q v.*), and the reaction with nitrosyl chloride was subsequently used by many workers in this field. Tilden also studied terpineol and related bodies, and the action of heat on terpenes In 1892 he observed the presence of a rubber-like substance in a bottle of isoprene which had been standing for some years, but owing to the fact that rubber was not then so valuable as it is to-day, the matter was not further investigated. In addition to his researches in organic chemistry Tilden contributed to physical chemistry. He determined the specific heats of elements at various temperatures, and thus showed the limits of applicability of Dulong and Petit's law. (*See* CHEMISTRY: *Physical.*) He also verified Neumann's law of the additivity of the specific heats of elements in certain compounds.

His published works include *An Introduction to Chemical Philosophy* (1876); *A Manual of Chemistry* (1896); *Chemical Discovery and Invention in the Twentieth Century* (1917); *Life of Sir William Ramsay* (1918); and *Famous Chemists* (1921).

TILE, a thin, flat slab, usually of burned clay, glazed or unglazed, used either structurally or decoratively in building. The usage of the word varies widely; in connection with roofing, flat slabs of any material are sometimes termed tiles, as for instance, the marble tiles occasionally used in Greek temples or the bronze tiles used extensively in ancient Rome, and occasionally in China. Similarly, stone slabs, used for roofing, as in certain parts of England, are termed stone tiles; slate, however, is never so called, and wood shingles are so called only rarely. Many forms of rough terra-cotta used structurally in building are called tiles; thus an arch of hollow terra-cotta blocks between steel beams is known as a "tile arch"; partitions built of hollow terra-cotta blocks are known as hollow tile partitions, and the steel forms used for casting certain types of reinforced concrete floors are frequently referred to as steel tiles. The differentiation between tile, terra-cotta and brick is thus exceedingly vague.

Tiles divide themselves naturally into several classes: structural tile, such as the hollow terra-cotta blocks referred to above, for which *see* TERRA-COTTA; roofing tiles; floor tiles; and wall tiles.

Roofing Tiles.—There is no evidence of the use of roofing tiles in the Mediterranean basin prior to the development of Hellenic civilization, but the most ancient examples of roof tiles we possess show such highly developed forms that earlier usage must be assumed. The Greek form of temple roof which remained constant throughout the history of Greek architecture consisted of two types of tile, used together. First the roof surface was covered with tiles generally flat, but with adjoining edges raised. These were laid in overlapping courses, and were all of equal size so that the joints of each course occurred directly in a line with those of the courses above and below. Convex covering tiles, also overlapping, were then laid over the joints of the flat tiles below, and were so profiled as to cover, not only the joint, but the raised edges of the lower tiles; in this manner an absolutely watertight roof could be produced. In order to make the architectural effect more delicate the ends of both lower tile and covering tile were rebated, so that the thickness of the overlapping portion was only half the thickness of the tile. At the bottom of each row of covering tiles was either a marble or tile upright, curved, decorative member known as an antefix (*q.v.*).

In some cases the covering tiles were of pointed, straight line section—the most common Greek type—in others a tile of semicircular section was used, easy to manufacture, but lacking in the extreme refinement of the other type; in the simpler domestic work, the lower courses were also of curved section, a segmental concave shape replacing the flat tile with raised edges. The marble tile used in some Greek temples, as in that of Bassae (*c.* 430 B.C., by Iktinos) is universally of the type with flat under tile and pointed covering tile, although at times, in order to reduce the number of joints, the covering tile and the under tile are cut from the same piece of marble.

Two other types of roof tile were common in Roman times and probably represent common Mediterranean types of much earlier origin. These are the so-called "Spanish tiles," with a contour resembling a letter S, in which the convex part of each tile fits over the edge of the concave portion of the next, and the shingle or flat tile found frequently in the Roman ruins of the northern provinces. These flat tiles are often of stone.

The usual material of all of these types of tile is burned clay, varying in colour from orange-yellow to purple-red. It is known, however, that bronze tiles were relatively common on the most monumental buildings of the Roman empire. Due to the rarity and value of bronze during the middle ages and the Renaissance, no examples of ancient bronze roof tiles are now known.

All of the classic forms of clay tile continued in use in various parts of the world during the mediaeval period, but their supremacy as a roofing material gradually yielded to lead and zinc for churches, public buildings, palaces, etc., and to slate, stone and thatch for the smaller private houses.

Clay roof tiles used at the present day remain of substantially the same form; improvements have been only in methods of manufacture and not in design. The flat tile designed to hook over roof battens or boards, is perhaps the most common type of small house roof covering in England and parts of France, and the combination of concave under tile and convex over tile is almost universal on pitched roofs in Italy, Spain, Greece and Turkey. The S-shaped tile is also common around the Mediterranean. The curved tiles are almost always laid in a heavy bed of waterproofed mortar, with ridges and hips covered by courses of overlapping tiles, similarly bedded; with flat tiles, the use of mortar is restricted to the convex or pointed tiles covering the hips and ridges. The best modern usage in laying tiles of this type demands the complete covering of the roof surface with a watertight material such as slaters' felt or heavy water-proofed paper, before the tile is applied. The tiles themselves are held in place sometimes by copper nails which secure the under tiles direct to the roofing and the covering tiles to wood battens which run up the slope of the roof under each row of covering tiles, and sometimes by copper wire brought up through two holes in each tile and twisted together. In America the popularity of houses of Spanish and Italian types has led to widespread manufacture of tiles both of the S-shape and alternately concave and convex.

Although various attempts have been made to imitate clay tiles in stamped metal and concrete, these imitations are so lacking

in the individual variation typical of ceramic ware that their use has been restricted to the cheapest type of jerry-built construction; their use, even there, is seriously questionable. Quite different are the roofing tiles of reinforced and water-proof concrete, which are common in industrial buildings, especially in Europe, although their use in America is increasing. These modern, industrial tiles are usually of large size—sometimes running to 4 ft. in length, and arranged to interlock, with the exposed surfaces grooved or channelled in such a way as to lead the water away from any joints. In these concrete tiles colouring matter is usually added in the material itself.

Roofing Tiles in the Far East.—Although the principle of the roofing tiles of China and Japan is the same as that in the West, there are many differences in detail. Thus, in temples and palaces in China, the under tiles are slightly concave and overlap, much like those of classic roofs; the covering tiles, however, are made absolutely cylindrical in general contour, with rebated ends, so that they form long, unbroken lines of shadow down the roof. Moreover, instead of the upright antefix of the classic roof, the Chinese tiles have ornaments that project downward, in generally scalloped shapes, over the face of the cornice. There is also, particularly in north China, a tremendous elaboration of ridge and hip tiles, which are frequently of great height, with an elaborately moulded section, and carry at their ends rows of animals, a great dragon or the like. At the ends of the ridge are large, grotesque beasts with their heads pointing inward; all these ornaments are modelled and baked in the tile itself. One of the chief glories of the Chinese roof tiles is their colour. This is produced by a shiny glaze that reveals the expected Chinese ceramic skill. The usual colour of temple and palace roofs is bright yellow but other colours frequently occur. In central and south China, even temple roofs are frequently black. The cheap roof tile of the ordinary house is also almost black, but without lustre and with overlapping covering tiles like those of the West.

The same pattern of rebatted, continuous, cylindrical covering tiles is common in the Buddhist shrines of Japan, but colours are rare, the ordinary tile being grey, with a very effective and artistic silvery lustre.

Floor Tiles.—Except as small fragments of tile occur in classic mosaic and terrazzo (*q.v.*), tile for floors does not seem to have been common in Europe prior to the 12th century. In the late 12th and 13th centuries, however, tile floors became usual in churches and other important buildings. The most common type consisted of square tile in two colours, usually a dark brown-red and a pale orange or brownish yellow. They were made by casting clay in such a manner that the parts to be in a lighter colour were sunk; when dry, these parts were filled with a clay of different composition which would burn to a lighter colour; the tile thus prepared was then burned. Patterns were formed of many tiles and consisted usually of circles or stars containing heraldic beasts, ecclesiastical symbols, etc.; in many cases the pattern was made with reversed colours, so that what was background colour in one tile was ornament colour in the one next it. In the earliest examples designs were formed by a mosaic treatment in which the pattern was made by the shape and size of the individual tiles, as in the 13th century example found at Fountains abbey and at Prior Crauden's chapel at Ely (1321–41), both in England. Other common types of mediaeval pavement have the pattern merely incised, producing the artistic effect of a sketch.

The development of floor tiles in Gothic France was similar. The 12th century examples are usually mosaic in type with black, dark green, light green and yellow as the predominating colours. The richest examples of these are in the abbey church of S. Denis, near Paris, where certain elaborate, chapel floor pavements still exist from the original building by Abbott Suger (1140–44). By

the end of the century, mosaic had yielded to two-coloured tiles of red and yellow, similar to the English tiles mentioned above. The same type remained constant until well into the 15th century, the designs becoming continuously thinner and more delicate; in the 16th century the art died out, superseded by the painted maiolica pavements of Renaissance feeling

The Gothic revival of the middle 19th century led, in England, to the revival of the designing and making of tiles of the mediaeval type and many modern pavements were placed in old churches as a result Most of this tile has a simple lead glaze and is made not by casting damp, plastic clay, as in the mediaeval examples, but by compressing powdered clay in steel dies so that shapes are more perfect and the rapidity of manufacture is vastly increased. This type of tile, usually known as "encaustic," is especially associated with the English ceramic works at Stoke-upon-Trent, particularly those of Minturn Recently, however, the manufacture of such tiles has become wide-spread in the United States and in Germany.

Meanwhile the Moorish skill in tile making had gradually come to be applied to floors. This type of maiolica tile was adopted in early Renaissance churches, both in Italy and Spain, although not many examples remain, as the glaze was too soft. The decoration of the Italian maiolica pavements consists of the same type of free and graceful classic arabesque trophies, acanthus ornament and coats of arms that is found on contemporary maiolica.

In France not only were Italian tiles imported and used, but there soon grew up a local manufacture of similar painted floor tiles, especially at Rouen (established by Masseot Abaquesne, 1542–57), Nevers and Marseilles With the increasing use of oak parquetry flooring for houses and marble for churches, toward the end of the 17th century, the use of tile diminished. There was similar importation of Italian and Spanish tiles into England during the early Renaissance and possible spasmodic attempts toward the making of certain types of this tile in England itself

In the 18th century the use of plain, undecorated, square, red tiles, now commonly known as quarry tiles, became common all over northern and western Europe, and to a less extent in the American Colonies

Although modern potteries all over the Western world are producing at the present time (1929) many varieties of elaborate, decorative floor tile, ranging from those in varied and brilliant colours with all sorts of blending glazes to the most complicated so-called Spanish tiles in relief, the greatest advances in modern floor tiles have been made in simple, vitrified, mosaic tiles for use in bath rooms, kitchens, swimming pools, etc. These are always machine pressed and are made of fine clays, thoroughly vitrified, and very hard. These are made in small squares, rectangles, hexagons and circles, in a few simple colours and are usually pasted, face down, on paper, in order to increase the speed of their application. (*See* MOSAIC) Some, by the addition of gritty substances, such as alundum or carborundum, are given a surface which prevents slipping, even when the tile is wet

Wall Tiles.—Earthenware was used spasmodically for wall decoration by the Egyptians, as in the doorway of the Abusir pyramid of Neterkhet (3rd Dynasty). More usually, however, they were in the form of mosaic (*q v*) Perhaps based upon earlier Egyptian examples, the people of Crete developed to an even higher degree the use of faience for walls. Thus our knowledge of early Cretan houses is largely furnished by many fragments of small faience plaques from the 18th century, B C., which formed portions of a large, mosaic, faience, wall decoration Moreover, there are in existence many modelled reliefs of faience from the middle and late Minoan period which were apparently inserted in the plaster of walls.

Farther east, in the Tigro-Euphrates valley, a tradition of ceramic wall decoration was early established (*See* WESTERN ASIATIC ARCHITECTURE.) This took the form of glazed and enamelled bricks rather than tiles proper It is, nevertheless, important, as being one of the first attempts to cover large and continuous wall surfaces with a decorative, ceramic material, and the friezes of marching beasts from Chaldean and Babylonian palaces, from the later Assyrian palaces and from their Persian successors, the famous friezes of the archers and the lions from the early 4th century palace of Artaxerxes II. at Susa, have remained models of this type of decorative work ever since. (*See* illustration of the Gate of Ishtar at Babylon, under BRICKWORK.) Moreover, the tradition of fine ceramic work continued vital throughout the stormy period of the fall of the Roman empire and the Mohammedan conquest It is in Syria, the Tigro-Euphrates valley and Persia that wall tiles were, undoubtedly, first made. Thus tradition relates that the lustre tiles of the mosque of Sidi Okba at Kairouan were brought from Baghdad in 894, and it is certain that by the 13th century the manufacture of wall tiles for both exterior and interior use was well established in various centres in Persia, notably Rhages and Veramine. The exterior use of wall tiles was most highly developed, and in Persia, also, the transition from enamelled and modelled brick to true, thin tile can easily be seen By the 15th century tile decoration was supreme in Persia and the character had changed. Mosaics and mouldings in relief yielded to a flat treatment with the richness entirely in the coloured, foliated ornament and the inscriptions painted on the tiles themselves. In later Persian art there is no distinguishable difference between the tiles of the exterior and the interior.

It was these Persian tiles which governed the taste of the eastern part of the Mohammedan world; the same running patterns of leaves, palmettes, the carnation and other flowers that appear on Persian carpets, decorate alike the interiors of mosques in Persia, Mesopotamia and Turkey, from potteries as far apart as Rhodes, Damascus and Kutayieh. In colour these have, universally, a blue-white ground with patterns predominantly blue and green and lesser touches of vermilion and rose and occasional yellows Several potteries in Asia Minor still operate and produce exquisite wall tiles in the traditional patterns and colours. Because of the gracious delicacy of the interlacing stems and the careful spacing of the leaves and flowers, together with a spring-like clarity of the colours, these Turkish, Syrian and Persian wall tiles are among the most perfect wall decorations of their type

Moorish Wall Tiles.—Farther west, in Spain and north Africa, the Mohammedan potters were developing a new type of design which gave rise to the famous Spanish *Azulejos*, whose decorative richness was such an important feature in the Alhambra at Granada (14th century), the so-called house of Pilate at Seville and similar buildings. Although transitional types occur, like the great plaque from Malaga at the beginning of the 15th century in the collection of M de Osma, in which the patterns are of an almost Persian freedom, with twining foliage, in the greater number the design was almost purely geometric, being formed of interlacing lines that generate 8- and 10-pointed stars, octagons, irregular pentagons and similar figures. There are, in addition, a great many early tiles from the 13th and 14th centuries in which the influence of Christian heraldry is dominant Even in the transitional plaque mentioned above, coats of arms appear and it is evident that the Mohammedan potters produced much purely heraldic tile work for Christian consumption Many of these tiles are rich with metallic lustre decoration; the chief colours are blue, green and brown, with white lines, and in the later work a growing use of black and yellow The earliest examples of Moorish wall tiles produced their geometric patterns by a mosaic method in which each bit of separate colour is formed by a separate tile. In order to develop a more facile method of producing the same effect, the technique known as *cuerda seca* (dry cord), in which the tiles are rectangular, and the pattern on each tile is formed by raised fillets between the different colours, which prevented the adjoining enamels from running together. After the Christian conquest a third method was introduced, called *cuenca* (bowl), somewhat similar to the northern Gothic process in which the portions to be coloured were depressed and then filled with their enamels. These tiles, even in their old traditional Mohammedan patterns, were popular throughout the 16th century and even later for wainscots in Renaissance houses. The potters were evidently Moors; the great centres of manufacture remained as before in Malaga, Valencia, Granada and Seville In the 16th century the Italian maiolica type of tile was introduced by Francesco Niculoso of Pisa, and these Spanish maiolica tiles

were much used, as in the door of the convent of S. Paula at Seville (early 16th century) or the exquisite altar-piece in the Alcazar at Seville made by the same artist in 1503, where the design is purely Italian. Both the *cuenca* and the *pisano* or majolica types of tile have been made in Spain almost continuously ever since, and the recent years have seen a great increase in the Spanish tile output both in Spain and for export.

Meanwhile in Germany there had been developing a type of tile used principally for stoves, with ornament in relief and a glaze of green, yellow or brown. This tile was in widespread use as early as the 14th century and many examples exist throughout Germany, upper Austria and Switzerland, in which the ornament is of great richness, with Gothic architectural forms in the earlier types and Renaissance forms later.

The most important of the north European tiles are undoubtedly those made in Delft from 1600 on. These are plain, square tiles, each containing a figure, a bit of landscape or a genre group, freely painted in a grey-blue upon a background of bluish-white. The little free-hand sketches were so instinct with life, and the colour so subtly beautiful that by the middle of the 17th century these tiles enjoyed a great vogue, not only throughout the Germanic countries, but in England and the American Colonies as well. Although outside of Holland they were chiefly used for fireplace and stove facings, in Holland itself they were often employed for wall wainscotings Some of the later examples have the decorations in manganese purple instead of blue During the 18th century many attempts were made to imitate the Delft ware and during the latter half of the 18th century, particularly in England, scenes printed from copper plates were used instead of the painted scenes

Although many of the ancient pottery centres are still producing tiles in the traditional manner and although modern imitations of old wares are of excellent quality, the greatest modern contribution to wall tile design has been the great development of square or rectangular tiles with relatively uneven surfaces and shapes on which colours and glazes of the greatest variety are unevenly flowed, so that each tile has marked individuality of colour and texture All sorts of crackled and crystalline effects are common as well as the blending of two or more colours The scientific development of glazings and colourings gives the decorator an almost unlimited palette for either exterior or interior use, even gold tiles being simple and comparatively inexpensive There has been a corresponding development in the use of tile in relief, usually with the background sunk and glazed in a different colour.

Important centres of tile production at the present day (1929) are: Asia Minor, for so-called Persian tiles; north Africa and Spain, for Moorish and Spanish tiles; north Italy for faience; Holland for "Delft" tiles, Belgium for many types of hand-made wall tiles; Germany for polychrome, machine-pressed floor tiles; England for reproductions of Gothic floor tiles and richly figured tile work generally; and the United States, particularly New Jersey, Pennsylvania, Ohio and southern California for vitrified floor and hand-made wall tiles.

TILE-FISH (*Lopholatilus chamaeleonticeps*), a beautifully coloured fish of the family Latilidae, living in rather deep water in the western Atlantic. It was first discovered on a bank about 80 m. S E. of Boston, and proved to be a valuable food fish.

The tile-fish is said to reach a weight of 50 lb, but about 10 lb. is more nearly the average size.

TILING OF ROOFS: *see* ROOFS; TILE.

TILLAGE. The word "tillage" is practically synonymous with cultivation (*q.v.*), but it is of Saxon derivation and older usage. It is often employed in the form "tillages" in tenant right valuations and denotes the operations by which land has been prepared for crops by the outgoing tenant.

Tillage conveys perhaps a simpler and more drastic significance than cultivation. The first implement of tillage was the spade and it still remains, after thousands of years, the most effective.

The importance of agricultural engineering has recently been recognized and investigations into theoretical and practical questions affecting tillage are in progress throughout the world. (*See* TRACTORS; AGRICULTURAL MACHINERY)

TILLEMONT, SÉBASTIEN LE NAIN DE (1637–1698), French ecclesiastical historian, was born in Paris on Nov 30, 1637. The boy was brought up in the little schools of Port Royal, and in 1660 he was made a tutor in the seminary of Buzenval, Jansenist bishop of Beauvais Ten years later he came back to Paris, and presently became a chaplain at Port Royal. In 1679 the storm of persecution drove him to settle on his family estate of Tillemont, where he spent the remainder of his life, dying on Jan. 10, 1698

From the age of twenty he was at work on his two great books—the *Mémoires pour servir à l'histoire ecclésiastique des six premiers siècles*, and the *Histoire des empereurs* during the same period. Both works began to appear during his lifetime—the *Histoire* in 1690, the *Mémoires* in 1693—but in neither case was the publication finished till long after his death There is a full account of his life in the 4th volume of Sainte-Beuve's *Port Royal*

TILLETT, BENJAMIN (1860–), British Labour politician, was born at Bristol, on Sept. 11, 1860 He started work in a brickyard at eight years, and was a "Risley" boy for two years He served six months on a fishing smack, was apprenticed to a bootmaker, and then joined the Royal Navy He was invalided out of the navy and made several voyages in merchant ships. He then settled at the London docks and organized the Dockers' union of which he became general secretary, taking a prominent part in the dock strike of 1889 He was one of the pioneer organizers of the General Federation of Trades, National Transport Workers' Federation, National Federation of General Workers, International Transport Federation, and of the Labour party For many years he was an alderman on the London County Council. He was M P for North Salford from 1917 to 1924, and was re-elected in 1929.

His publications include *A Brief History of the Dockers' Union* (1910), and *A History of the Transport Workers' Strike* (1911).

TILLEY, SIR SAMUEL LEONARD (1818–1896), Canadian statesman, was born at Gagetown, New Brunswick, on May 18, 1818, the son of Samuel Tilley, an American Loyalist, who had settled in St John in 1783. From 1860 to March 1865 he was premier of the province, and was prominent in organizing the conference on the union of the maritime provinces, which met at Charlottetown in 1864, and which soon widened into a discussion of Canadian federation In 1865 he was defeated in a general election on the federation question, but returned to power in 1866, partly through an intrigue of the colonial office From 1868 till November 1873 he held various portfolios in the Dominion cabinet; from 1873 to 1878 he was lieutenant-governor of New Brunswick, but in 1878 was again elected as member for St John, and entered the Conservative cabinet as minister of finance. Later in 1878 he introduced and carried through parliament the "national policy" of protection, on which issue the election of 1878 had been won. The tariff so introduced became the basis of Canadian financial policy. In October 1885 ill health forced him to retire from the cabinet. He was again lieutenant-governor of New Brunswick from 1885 to 1893. He died on June 25, 1896.

His *Life*, by James Hannay (1907), forms one of the "Makers of Canada" series.

TILLODONTIA, a group of extinct mammals from the Eocene of North America and Europe. The average size was about that of a living brown bear. The canine teeth are very

small, one pair of incisors in each jaw much enlarged and chisel-like The general structure is very primitive, the brain small and elongate, the cheek teeth of generalized (tuberculo-sectorial) type, the feet plantigrade, with five toes. The skull is more carnivore- than rodent-like in general aspect. The best known genera are *Tillotherium*, *Esthonyx* and *Trogosus*. Despite the relative large size of its members, the group is probably more suggestive of the Insectivora than of any other established order and it is apparently an early, extinct, rather aberrant offshoot of the earliest stock of the placental mammals. (G. G. Si.)

TILLOTSON, JOHN (1630–1694), English archbishop, was the son of a Puritan clothier in Sowerby, Yorkshire, where he was born in October 1630. He was a fellow of Clare Hall, Cambridge, and about 1661 he was ordained without subscription by T. Sydserf, a Scottish bishop. Tillotson was present at the Savoy Conference in 1661, and remained identified with the Presbyterians till the passing of the Act of Uniformity in 1662. Shortly afterwards he became curate of Cheshunt, Herts., and in June 1663, rector of Kedington, Suffolk. He now devoted himself to an exact study of biblical and patristic writers, especially Basil and Chrysostom. The result of this reading, and of the influence of John Wilkins, master of Trinity College, Cambridge, was seen in the general tone of his preaching, which was practical rather than theological. In 1664 he became preacher at Lincoln's Inn. The same year he married Elizabeth French, a niece of Oliver Cromwell; and he also became Tuesday lecturer at St Lawrence, Jewry. In 1670 he became prebendary and in 1672 dean of Canterbury. In 1675 he edited John Wilkins's *Principles of Natural Religion*, completing what was left unfinished of it, and in 1682 his *Sermons*. With Burnet, Tillotson attended Lord Russell on the scaffold in 1683. It was partly through Lady Russell that he obtained influence with Princess Anne, who followed his advice in regard to the settlement of the crown on William of Orange. He possessed the special confidence of William and Mary, and was made clerk of the closet to the king and dean of St. Paul's. On his advice the king appointed an ecclesiastical commission for the reconciliation of the Dissenters. He was elected to succeed the Nonjuror Sancroft as archbishop of Canterbury, but accepted the promotion with extreme reluctance, and it was deferred from time to time, at his request, till April 1691 In 1693 he published four lectures on the Socinian controversy. He died on Nov. 22, 1694.

Ralph Barker edited his *Sermons* together with the "Rule of Faith" (14 vols. 1695–1704). In 1752 an edition of his *Complete Works* appeared in 3 vols, with *Life* by Thomas Birch.

TILLY, JOHANN TZERCLAES, Count of (1559–1632), general of the Catholic League in the Thirty Years' War, was born in 1559 at the château of Tilly in Brabant. He was destined for the priesthood and received a strict Jesuit education. But, preferring the career of a soldier, he entered a Spanish foot regiment about 1574 as a volunteer, and in the course of several campaigns rose to the command of a company. This being reduced, he again became a simple pikeman, and as such he took part in the famous siege of Antwerp by Parma. He distinguished himself by his bravery, and the duke of Lorraine gave him the governorship of Dun and Villefranche, which he held from 1590 to 1594. Henry IV. attempted unsuccessfully to induce him to enter the service of France. Somewhat later he left the Spanish service for that of Austria to fight against the Turks. In 1602 he became colonel in the imperial army, and raised a regiment of Walloon infantry which he commanded in the assault on Budapest, receiving a severe wound. In 1604 he was made general of artillery; having shown great capacity and devotion to the emperor and the Catholic religion, he was made a field-marshal in 1605. In 1610 he left the service of the emperor to enter that of Maximilian, duke of Bavaria, the head of the Catholic League. In 1620 he became lieutenant-general to Maximilian and commander-in-chief of the field forces.

With the victory of the White Mountain (1620) the new army and its leader became celebrated throughout Germany and the subsequent campaigns (*see* Thirty Years' War) established their reputation. The battle of Höchst (1622) won for Tilly the title of count.

The defeat of King Christian was soon followed by the intervention of Gustavus Adolphus. The opening stages of the campaign did not display any marked superiority of the Swedes. At this time Tilly was commander of the imperial forces as well as of his own army. The first great contest was for the possession of Magdeburg (1631). Tilly has been blamed for the atrocities which accompanied the sack of this town after its fall (May 20). Yet his personal exertions saved the cathedral and other religious buildings from pillage and fire Four months later Tilly and Gustavus, the representatives of the old and the new art of war, met at Breitenfeld (*q.v.*). The victory of Gustavus was complete, though the imperial general, although severely wounded, drew off his men in good order. On the Lech, a few months later, Gustavus was again victorious, and Tilly received a mortal wound He died on April 30, 1632, in Ingolstadt.

See O. Klopp, *Tilly im 30-jährigen Krieg* (Stuttgart, 1861); K Wittich, *Magdeburg, Gustav Adolf und Tilly;* also memoir of Tilly in *Allg. deutsche Biographie;* Keym-Marcour, *Johann Tzerclaes, Graf v. Tilly;* Villermont, *Tilly, ou La Guerre de trente ans* (Tournay, 1859).

TILSIT, a town in the Prussian province of East Prussia, situated on the left bank of the Memel or Niemen, 57 m. S E. of Memel and 72 N.E. of Königsberg by rail. Pop. (1925) 51,071. Tilsit, which received civic rights in 1552, grew up around a castle of the Teutonic order, known as the "Schalauner Haus," founded in 1288. It owes most of its interest to the peace signed here in July 1807, the preliminaries of which were settled by the emperors Alexander and Napoleon on a raft moored in the Memel This treaty, which constituted the kingdom of Westphalia and the duchy of Warsaw, registers the nadir of Prussia's humiliation.

TIMAEUS (*c.* 345–*c.* 250 B C), Greek historian, was born at Tauromenium in Sicily. Driven out by Agathocles, he migrated to Athens, where he studied rhetoric under a pupil of Isocrates and lived for 50 years. During the reign of Hiero II he returned to Sicily (probably to Syracuse), where he died. While at Athens he completed his great historical work. The *Histories*, in at least 38 (Bury says 33) books, was divided into unequal sections, containing the history of Italy and Sicily in early times; of Sicily alone; of Sicily and Greece; of the cities and kings of Syria (unless the text of Suidas is corrupt); the lives of Agathocles and Pyrrhus, king of Epirus. The chronological sketch ('Ολυμπιονῖκαι, the victors at Olympia) perhaps formed an appendix to the larger work. Timaeus was bitterly attacked by other historians, especially by Polybius.

The most serious charge against Timaeus is that he wilfully distorted the truth, when influenced by personal considerations. thus, he was less than fair to Dionysius and Agathocles, while loud in praise of his favourite Timoleon. On the other hand, as even Polybius admits, Timaeus consulted all available authorities and records. His attitude towards the myths, which he claims to have preserved in their simple form, is preferable to the rationalistic interpretation under which it had become the fashion to disguise them. In chronology, he introduced the system of reckoning by Olympiads, with which he compared the years of the Attic archons, the Spartan ephors, and the priestesses of Argos This system was afterwards generally used by the Greek historians. Timaeus' prose is of the Asiatic school; Cicero praises it.

TIMARU, a seaport of Geraldine county, New Zealand, on the E. coast of South Island, 100 m. S.W. of Christchurch by rail. Pop. (1927) 15,635. The slight inward sweep of the coast forms the Canterbury Bight, and the shore-line northward from

Timaru is called the Ninety-mile Beach. The harbour is formed by breakwaters enclosing a space of 50 acres. Chief exports are wool, flour and frozen meat, and the industries are in connection with these. Opals are found in the district. Timaru is the chief town in South Canterbury district.

TIMBER. The terms "wood" and "timber" are not synonyms, for wood occurs in the veins of leaves and as strings in thick palm-stems, also in thicker cylindrical form in twigs of shrubs and trees. The term timber, synonymous with the North American term *lumber,* applies solely to wood of considerable dimensions produced by trees. (*See* LUMBERING.)

Two great classes of trees provide timber. (1) *Conifers,* including pines, spruces and larches, usually have more or less needle-like leaves, and their naked seeds are most frequently borne on cones: they yield the so-called *softwoods.* (2) *Dicotyledons,* including oak, ash, beech and teak, commonly have broader flat leaves and their seeds are always produced in closed seed-cases: they provide the *hardwoods.*

Origin and Structure of Timber.—The part of the tree above ground typically consists of a main *trunk* and the branch-system whose ultimate finest branches are the leaf-bearing twigs.

The trunk and branches grow in *length* solely at their tips, so that the oldest part of a trunk or branch is its base and the youngest is its slender tip But after a portion of a trunk or branch has ceased to grow in length it can grow in *thickness* year after year and especially by producing new wood This takes its origin from a microscopically thin sheet, the *cambium,* lying between the bark and the wood: the cambium deposits new wood outside the pre-existing wood. In the cool-temperate climate the cambium produces new wood only during spring and part of the summer and is inactive during autumn and winter: the wood produced first in each year is frequently (*e g.,* ash, Scots pine) different from that produced later in the year, so that a distinction is drawn between the early *spring-wood* and the later *summer-wood* (frequently termed *autumn-wood*). In such cases a cross-section of the tree-trunk will show a number of concentric *annual rings,* whose number is equal to the age of the region of trunk cut. In the case of the beech and a number of other trees, the annual rings show no marked differentiation into spring-wood and summer-wood, but are recognisable because a very thin layer produced latest in the growing season differs in appearance from the rest of the wood. Finally many kinds of evergreen tropical trees (*e.g ,* mahogany) show no distinct annual rings

In certain kinds of trees, for instance species of pines and leaf-shedding oaks, after the wood has attained a certain age it darkens in colour, so that when a cross-cut of a 100-year old part of the trunk is taken the darker older central wood contrasts as *heart-wood* with the surrounding pale *sap-wood.*

Structure of Wood.—With the aid of the microscope it can be seen that a softwood consists mainly of very narrow hollow spindle-shaped "fibres" (properly, tracheids), running parallel to the long axis of the trunk or branch The solid wall of each fibre consists of wood-substance and on at least two of its sides shows a series of thin round patches, the pits, through which water or sap can pass from fibre to fibre.

In addition to the fibres, certain softwoods, including those of true pines, have very thin resin-containing tubes, the *resin-ducts,* which run parallel with the fibres. In structure each duct in microscopic miniature recalls a tall factory chimney, as its central tubular hollow is surrounded by microscopic, short, more or less brick-shaped cells, which are hollow and have thin walls. All commercial softwoods (excluding that of the yew) contain resin but some of them (*e.g.,* Californian redwood) have in place of resin-ducts merely resin-containing short cells.

Traversing the wood at right angles to the fibres are thin string-like or ribbon-like structures that run from the outside of the wood radially inwards towards or actually to the pith. These are the *medullary rays,* which are usually nearly or quite invisible to the naked eye in cross-sections of softwoods. They consist of more or less brick-shaped cells, which in the sap-wood contain albuminous substances and at times such other nutritive substances as sugar, starch or fatty oil: in the sap-wood they consequently invite attack by animals and fungi. Softwoods that, like true pines, have resin-ducts in the wood also possess these in the thicker medullary rays.

The fundamental difference between softwoods and hardwoods is best understood if we imagine a number of the wider "water-fibres" very greatly widened and strung end to end with their terminal walls absorbed, so that long continuous tubes, sometimes yards in length, are produced. These water-conducting tubes are termed *wood-vessels:* in cross-section they are often visible to the naked eye as *"pores"* All commercial hardwoods have wood-vessels, which in the sap-wood contain air with or without liquid sap In addition to the vessels, the different hardwoods have "fibres" of various forms.

Finally medullary rays are present, and in many hardwoods some of them are much thicker than in softwoods and visible to the naked eye in cross-section, producing the so-called "silver grain" on the radial side view of the wood of, for instance, oaks, beech, plane, etc. Their contents in the sapwood are identical with those of softwoods.

Sap-wood and Heart-wood.—The change of sap-wood into heart-wood is a vital one, occurring only in the living tree, and thus is very different from the process of seasoning of timber which takes place *post mortem.* The sap-wood is living inasmuch as its brick-shaped cells contain living protoplasm· the heart-wood is dead, as the protoplasm dies and the cells lose their nutritive contents, which are replaced by air and more indigestible substances such as "tannin," gums and resin The heart-wood contains less water than the sap-wood, and its water-conducting elements ("fibres" and vessels) become more or less plugged by microscopic bladders or gums, or the pits are closed Consequently sap-wood is more easily impregnated with wood-preservative liquids than is heart-wood of the same tree. In different trees the age at which sap-wood first changes to heart-wood differs. for instance the change takes place earlier in larches than in true pines, so that the former have fewer annual rings of sap-wood outside the heart-wood and produce valuable durable heart-wood earlier in the life of the tree, and contain a smaller proportion of the perishable sap-wood (*see* DRY ROT).

Grain of Timber.—Most frequently the fibres and other structural elements of knotless timber run parallel with the long axis of the trunk or branch, and the wood is described as being *straight-grained.* If a plank or post be sawn in a direction not parallel to the axis of the trunk, the grain of the sawn article is not parallel to the sides of this and the plank or post is described as *cross-grained* But not infrequently the grain of the trunk (or branches) runs in a spiral direction as if the trunk had been twisted round its long axis: the grain is then described as *spiral* or *torse,* and the timber when cut up is inevitably cross-grained There are yet other, especially tropical, woods in which the grain more or less swings from a left-handed to a right-handed spiral direction, so that the wood when cut into plain boards shows a *double cross-grain* or *interlocked grain,* and when cut along the radii of the trunk ("on the quarter," rift-sawn) shows *roe-figure,* for instance in mahogany.

In addition to these deviations from the straight grain the structural elements of the wood may pursue a wavy or *sinuous* course, for instance in so-called rammy-ash. When the waviness is exaggerated the grain is said to be curly.

Knots, being the basal parts of branches that have become embedded in the thickening trunk, are naturally associated with a change of direction of the fibres The wood of large excrescences on the trunk of certain trees known as *burrs* exhibits structure similar to that which would be produced by many crowded branches: and a somewhat similar structure is shown by bird's eye maple.

The fibres of most timbers overlap and dovetail with one another at their ends, which are at different levels, and the medullary rays as seen in circumferential or tangential view are arranged apparently irregularly or in spirals But some woods when examined from the same view-points show lines running across the grain and producing what is known as *ripple-marking:* this is

caused by either contiguous fibres ending at the same levels with little or no overlapping or medullary rays placed at the same levels, so that the structure of the wood is *tiered.* Such structure is often shown by true American mahoganies

Chemical Composition.—The wood-substance composing the walls of the hollow structural elements that constitute the solid frame-work or skeleton of wood may, for the present purpose, be regarded as always being composed of two main constituents, *lignone* and *cellulose,* together with smaller quantities of additional more or less gum-like bodies The lignone can be removed from the wood by steam or warm weak acids (and is so removed in the manufacture of chemical wood-pulp), the cellulose remaining.

The various substances here described collectively as cellulose are carbohydrates, which may be popularly defined as sugars or substances capable of being converted into sugars Thus cellulose of wood yields for instance a sugar, glucose, which by fermentation can produce ethyl alcohol (spirits of wine) Cellulose by appropriate treatment with nitric or acetic acid produces soluble compounds which when precipitated serve to make artificial silk, dopes, films (collodion, etc.), and in the case of nitric acid, explosives

The general agreement of all kinds of timbers as regards chemical composition is illustrated by the fact that all these under destructive distillation yield tar and tar-derivatives and methyl alcohol (wood spirit).

But the various kinds of wood also have additional chemical bodies which differ in the different species, and include tannin-like bodies, resins, scented ethereal oils and colouring substances

Physical Constitution.—Physically wood-substance is a very stiff jelly or *gel,* and consequently is comparable with glue, gelatin or gums Like these, it is hygroscopic and swells as it absorbs water and shrinks as it dries Wood-substance can take up only a definite amount of water, which lies near 30% of its dry weight when the wood is in a saturated atmosphere A piece of wood containing this maximum amount in its walls but none in its cavities is described as having reached *fibre-saturation point,* and has attained its maximum volume: when liquid water is added to it the water remains in the cavities and no additional swelling ensues.

It is a familiar fact that when water is added to dry glue or gelatin these show a decline in hardness, strength and stiffness, and a rise in flexibility and extensibility: as wood-substance is a gel, the same changes in its properties take place when water is added to a piece of dry wood until fibre-saturation point is reached. Moreover, just as when heat is applied together with water to glue this shows increased loss of stiffness (by "melting"), so when moist steam is applied to wood this can readily be bent for the manufacture of furniture and so forth

The weight or heaviness of wood is recorded as the weight of a unit of volume of the wood, which is the density The units employed in the British Empire and United States are cubic feet and pounds avoirdupois: elsewhere, and in scientific work, they are cubic centimetres and grammes

Since the fundamental chemical composition of wood-substance approaches identity in all timbers, its specific gravity in these varies but slightly and lies near 1·55; that is, dry wood-substance weighs slightly more than one and a half times as much as water. Consequently when two perfectly dry pieces of wood of equal size differ in weight, the one is heavier than the other because it contains more wood-substance, in other words the density of perfectly dry wood is a measure of the amount of wood in a unit volume The various kinds of timbers differ in their densities, some woods, including ebony and box, even when fully seasoned, sink in water, whereas some balsa-woods are lighter than cork. Consequently density facilitates identification of different woods.

Water Content.—The amount of water present in a piece of wood is of profound practical importance, since it determines the weight (consequently cost of transport), size, shape, heat-raising power, hardness, strength and stiffness of the piece, as well as the vulnerability of the wood to attacks by fungi and insects: it also determines the changes in these characters that will ensue when the wood is transferred to another place.

In commerce the water-content of the wood is recorded as the percentage weight of the wood and contained water, but in scientific work and in this article, as a percentage weight of the wood when it is absolutely dry. According to the latter method of recording, a log of wood is described as containing 200% of water when it contains 200 lb of water to every 100 lb. of dry wood. Such a high water-content does occasionally occur naturally, for instance in freshly felled swamp (Louisiana) cypress; more frequent in freshly felled timber is 100% in the sap-wood. Heart-wood contains much less. Here a popular error must be corrected in cold-temperate regions the wood of a tree does not contain less water in winter than in summer; often the reverse is the case.

When exposed to the open air, preferably under cover, a freshly felled piece of wood dries and shrinks until the water-content at its surface has a vapour pressure equal to that of the atmosphere The water-content of pieces of timber thus seasoned in the open air, and not too massive, varies according to the season and site between 15 and 20% in Great Britain but is much less in drier climates, for instance, that of Egypt, in which it may be 6%

Brought indoors into heated work-shops or rooms further drying and shrinking takes place, so that furniture in Great Britain contains about 7 to 9%, and in drier parts of South Africa and the United States only 6% or less

Placed in a drying oven at a temperature of 100°C, all the water, save that which is chemically combined, is regarded as having been dried out and the wood is described as absolutely dry. When dry wood is once more exposed to moister air it reabsorbs water and swells.

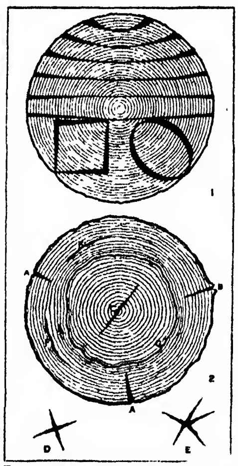

FIG 1.—SHRINKAGE AND CHANGE OF SHAPE INCLUDING WARPING
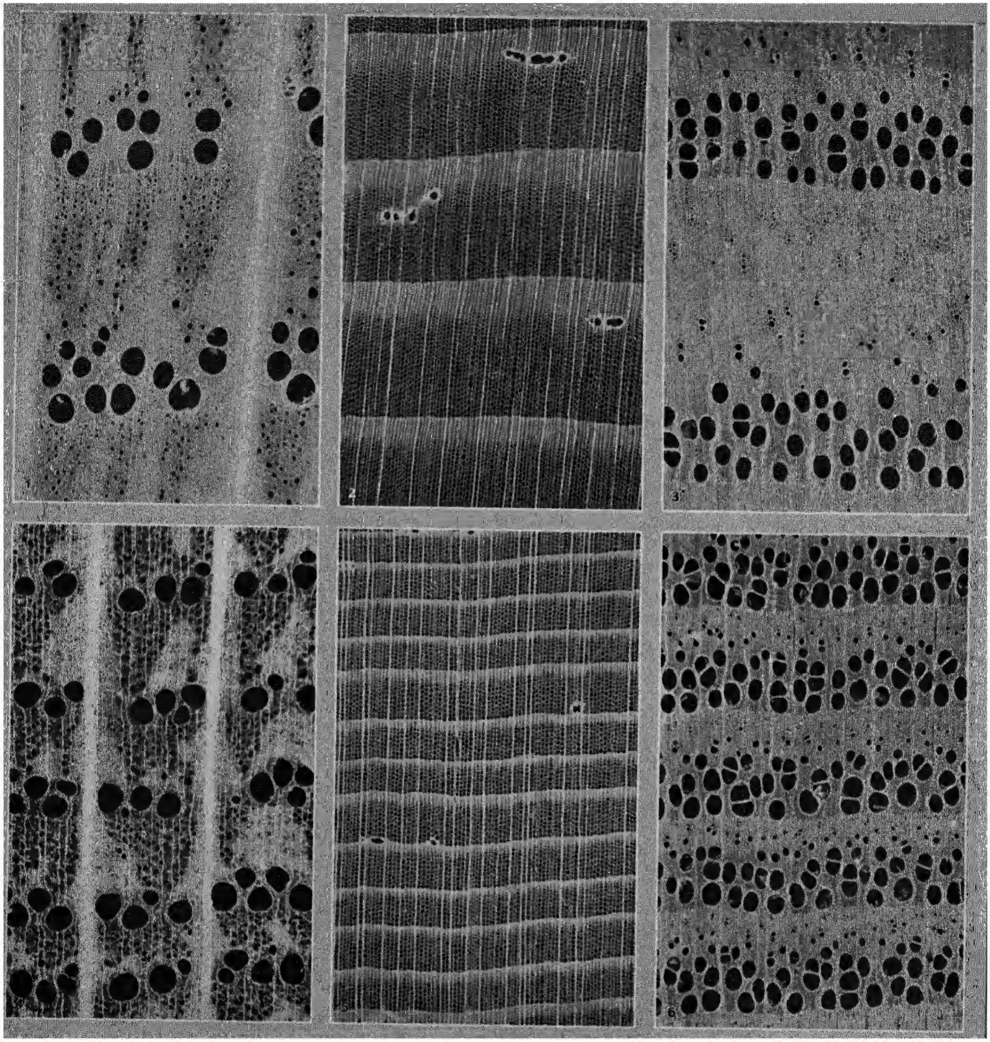
FIG. 2 —SHAKES AND SPLITS (A) SEASONING SPLIT (B) FROST-RIB AND SPLIT (C) SIMPLE HEART-SHAKE (D) DOUBLE HEART-SHAKE (E) STAR-LIKE HEART-SHAKE (F) PARTIAL CUP-SHAKE (G) COMPLETE CUP-SHAKE

Different kinds of wood undergo different changes of volume with the same percentage gain or loss of water: heavy or non-resinous woods generally shrink or swell more than do light or resinous woods, with the consequence that softwoods usually show smaller changes of shape and volume than do hardwoods. But shrinkage and swelling are not proportional to density, for non-resinous woods of the same density show considerable differences in this respect; for instance, Central American mahogany with changed water-content undergoes comparatively slight change of size and shape

A piece of wood tends to shrink and swell unequally in different directions. Along the grain shrinkage and swelling are so slight that measuring rods made of well-seasoned wood are very reliable. Across the grain shrinkage and swelling are many times as great: in a radial direction 30 to 50 times and tangentially (or parallel to the annual rings) 60 to 100 or more times Consequently when a piece of wood dries it undergoes greater or less change of shape. The accompanying diagrams show cross-sections of pieces of wood respectively cut into boards, joists and cylindrical rods, and the change of shape caused by drying; the warping of boards 2 to 4 contrasts with the preservation of flatness of board 1 which is cut nearly parallel to the radii (quarter-cut or rift-sawn).

A piece of wood whose fibres, like those of very knotty wood or burrs, run in various directions obviously is especially liable to split when dried. It is partly for this reason that the burr-wood used in the manufacture of beautifully figured furniture is cut



BY COURTESY OF THE FOREST PRODUCTS RESEARCH LABORATORY OF GREAT BRITAIN AND THE IMPERIAL FORESTRY INSTITUTE OF THE BRITISH EMPIRE

MAGNIFIED TRANSVERSE SECTIONS OF TIMBER

Upper and lower photographs illustrate respectively broad and narrow annual rings of Oak, *Quercus robur* (1, 4), Douglas Fir, *Pseudotsuga taxifolia* (2, 5), and Ash, *Fraxinus excelsior* (3, 6). The spring-wood of their annual rings, produced at the beginning of the growing season, is more open or porous, and weaker than the summer-wood, produced later in the season. The proportion of weak spring-wood is greater in the wide than in the narrow rings of the Douglas Fir, but the reverse is the case in the Oak and Ash

into very thin sheets, termed *veneers,* which are glued on to straight-grained wood. *Plywoods* (including the commonest of these, three-plywood) consist of thin veneer-like sheets glued together so that the grains of the successive sheets cross one another at a given angle (usually at right angles), with the consequence that plywood warps less and shrinks more uniformly than does plain wood and is less unequal in strength in different directions.

Colour.—The different kinds of wood may be wholly white or in the heart may be black or have colours ranging from brown, yellow, red, green to violet, or mixtures of these. It is quite exceptional for one and the same wood when perfectly sound to show such a wide range of variation as does that of *Liriodendron* (whose English name is Canary white wood and North American name is yellow poplar): this wood varies in colour from light yellow to green and iridescent blue. The colour thus facilitates identification and helps to decide the decorative use to which a wood shall be put. It is not true that dark coloured woods are more durable than light coloured, though this is true of the heart-wood when compared with the sap-wood of the same timber. Abnormal discolouration of wood is very frequently caused by fungi attacking the wood or its contents, such as the case with the *blue sap(wood)* of softwoods, rusty red of woods attacked by various fungi (including some causing dry rot), black lines and white patches of many rotting timbers, and sometimes false heart-wood in trees which normally lack a coloured heart-wood

Heating Power.—The heat-yielding power of a piece of wood sinks with increase of the water-content of this. consequently the succeeding remarks refer to wood absolutely dry. During the combustion of wood the heat liberated is mainly derived from the wood-substance. as the weight of this in a unit volume of wood is the density, it follows that the heavier a wood is the more heat can it supply. the presence of resin in wood, however, increases the heat-giving power. But when wood is used as fuel the most important character often is the form in which the heat is liberated Very heavy woods produce short or no flames and burn slowly, light woods can produce long flames and burn fiercely: consequently for fire-lighting or steam-producing the latter are used, whereas for keeping rooms warm, woods of intermediate density (*e g.,* oak, beech) are most efficient

Mechanical Properties.—The trunk and woody branches of a tree owe their strength and stiffness mainly to their wood Accordingly, wood must possess strength to resist breakage or permanent damage by slow crushing, stretching, bending and twisting; it must also resist shock in the form of sudden application of these stresses it must possess sufficient stiffness to give the requisite pillar-strength to the trunk, and when a deforming stress is removed must return to its former shape.

In conformity with its difference of structure along and across the grain, wood differs in strength and stiffness in these two main directions. As regards crushing (compression) and stretching (tension) wood is strongest and stiffest along the grain, and weakest at right angles to this: but as regards shear it is strongest at right angles to the grain: a beam in bending is strongest and stiffest when the load is applied perpendicular to the grain Consequently, joists, beams, floor-boards, posts, axe-handles, wheel-spokes and so forth are strongest when their grain is straight and parallel to the sides of these objects, and they are weakened by cross-grain and considerable knots.

The remarkable mechanical property of wood is its combination of strength and lightness: for instance, if the crushing strength be divided by the density in the cases of constructional wood and iron, steel and other metals, the resultant value is highest in wood Nevertheless, the tensile strength of steel or iron is so much higher than that of wood that one of the former is used in engineering construction for members required to resist rupture by tension, whereas wood is often used where resistance to bending or compression is needed. (*See* STRENGTH OF MATERIALS.)

The peculiar *elastic* properties of wood render possible its employment as resonance-wood, used for instance in the bellies of violins, and the sounding boards of pianos. Wood undergoing decay soon declines in strength and elasticity, and even when only partly decayed emits when struck a dull, in place of a sharp ringing sound.

Wood, thanks to its structure, elasticity, low tensile strength, and relative softness, can be riven or *cleft* along the grain and yields a more or less smooth surface.

Defects of Timber.—(*a*) *Standing Tree.* Wood may have structural peculiarities that represent defects from the mechanical point of view but may enhance the value because of the decorative effect. This is the case where *deviations of the grain* such as wavy or curly grain, or abundance of knots, weaken the wood.

Always decreasing the value of timber are long splits, termed *shakes,* directed along the grain of the standing tree. These in cross-section may run parallel with the annual rings (or contour of the trunk) and are termed *cup-shakes,* and may assume the form of short arcs or complete circles (*ring-shake*): in the latter case when the log is sawn the central part separates from the outer part. But in cross-section the shake may run in a radial direction, it is then a *heart-shake* such a shake is widest towards the centre and tapers outward, and contrasts with the radial splits induced by drying of the felled timber which are wider at the outside and taper inwards Heart-shake may assume the form, in cross-section, of a single split traversing the centre and is described as *simple,* or this split may be crossed at right angles by another thus producing *double* heart-shake, or, finally a number of splits may radiate from the centre and thus constitute *star-shake,* which is often associated with discolouration and decay Radial *frost-shakes* are frequently associated with "frost-ribs" that are visible on the growing tree as ridges running down one or more sides of the trunk With these shakes contrast the internal radially directed splits that first arise in felled timber which has been so rapidly dried that "*case-hardening*" has resulted.

In coniferous wood resin-containing cavities, known as *resin-pockets* or *pitch-pockets,* occasionally occur: they are of varied dimensions but usually of width quite considerable in comparison with the length Sometimes longer *resin-veins* easily visible to the naked eye traverse the wood or this may clearly show a general excess of resin in the absence of veins or pockets. In some cases excess of resin or abnormal development of the ducts is due to wood-attacking fungi. In hardwoods so-called *gum-veins* are occasionally present in Australian species of *Eucalyptus,* including jarrah, and in true mahoganies

(*b*) *Felled Timber.*—Tunnels or other cavities are also produced by animals in felled timber. In sea-water they result from attacks by Mollusca (*e g.,* shipworms) or small Crustacea (*cf* shrimps), and on land are due to insects. Decay or rot of timber taking place in the standing tree or felled timber is always due to fungi (*see* DRY ROT), and is associated with discolouration and weakening of the wood but much less frequently with the production of internal cavities.

Opposed to the shakes already considered are *cross-shakes,* which are cracks or splits running at right angles to the grain In the overwhelming majority of cases they are due to decay of the wood, caused by fungi, and consequent shrinkage (*see* DRY ROT) They render wood useless for mechanical usage. But the logs of certain species of trees, including spruce, sabicu and some African mahoganies, occasionally show cross-shakes, even when there is no trace of decay.

For a discussion of Felling, forms and sizes *see* LUMBERING *See* also TIMBER PRESERVATION

Special Softwoods.—The name cedar is given to various unrelated, usually fragrant, softwoods and hardwoods. The true cedars (*Cedrus*) are familiar as trees of three kinds: the Himalayan deodar, the cedar of Lebanon and the Atlas Mountains cedar. Junipers (*Juniperus*) supply the *pencil-wood cedar,* the most important being the North American *J. virginiana,* though pencil slats are also made from another species growing in Kenya Colony: the heartwood is durable, as the scented cedar-wood oil is antiseptic and distasteful to insects Lawson's cypress (*Chamaecyparis Lawsoniana*), indigenous in western United States. yields the valuable *Port Orford cedar.* Other North American cedar woods are produced by arbor vitae trees (*Thuja*), the durable red cedar wood (*T. plicata*) being used for shingles.

Bald, marsh or Louisiana cypress (*Taxodium distichum*) grows

in swamps of south-eastern United States and Central America: its durable wood is unsurpassed for conservatories.

The European larch (*Larix decidua*) is rather heavy and the red heartwood is very durable. The rather similar North American timbers are those of the tamarack (*L. americana*) and the western larch (*L. occidentalis*). Larch timbers find many of the same uses as hard-pines (*see* later).

Pine, true.—The name pine is given to a medley of softwoods, but should be restricted to timbers belonging to the genus *Pinus*. Such genuine pine-timbers may be ranged into two classes, hard-pines and soft-pines, the former of which are generally heavier.

Hard-pines include one of the two most important softwoods of Europe, Baltic "red deal" (*Pinus sylvestris*, the Scots pine), which grows widely over Europe, and is represented in North America by a very similar timber, red or Norway pine (*P. resinosa*). The name pitch-pine as applied to North (and Central) American timbers in Great Britain and the United States, respectively, is liable to cause confusion: in the latter country it refers to relatively poor wood of *P. rigida*, whereas in Great Britain and Europe it refers to pine-timbers of the highest class produced by *P. palustris* and two or three other species all exported from south-eastern United States to England.

Soft-pines include the timber of the American Weymouth pine (*Pinus Strobus*), which is known in England as "Canadian yellow pine" and in the United States as "Eastern white pine": it is not used out of doors, but for making matches, patterns and for high-class cabinet work.

Pines, so called—A wide range of coniferous trees are known in Australasia as pines, and include the Kauri-pine (*Agathis australis*) of New Zealand, and Huon-pine (*Dacrydium Franklinii*) in Tasmania The Oregon or British Columbian pine is Douglas fir (*Pseudotsuga taxifolia*) which grows in the Pacific States of North America.

Californian redwood (*Sequoia sempervirens*) has a reddish heartwood light in weight, very durable, and used for the manufacture of shingles and patterns.

White deal is the wood of the Norway spruce (*Picea excelsa*) which is wide-spread over Europe. The white wood ranges in quality from the common grades used in packing cases, woodwork of houses and pulp, to mountain-grown wood of the highest quality which provides the best sounding boards of pianos. To similar uses the black, white, red and Sitka spruces (*Picea* spp.) are put in North America (*See* SPRUCE)

Special Hardwoods.—The ash-tree (*Fraxinus excelsior*) is widespread over Europe and supplies the timber of commerce, which is almost solely sap-wood, as any heart-wood is produced late in life The wood is remarkably tough and, after steaming, can be permanently bent without losing its shock-resisting power It is used in the manufacture of axe-handles, oars, bodies of carriages and motor-cars, hockey-sticks and so forth. In North America six species of *Fraxinus* supply commercial timbers.

The beech-timbers of commerce are the woods of *Fagus sylvatica* and *F. americana* in Europe and North America respectively The latter shows a distinction into white sap-wood and reddish heart-wood, but not so the former which is of uniform reddish white Being perishable out of doors beech-wood is mainly made into articles used indoors, including furniture.

In addition to the softwoods enumerated a number of scented hardwoods from various countries are termed cedars: of these the most familiar is the tropical American cedar (*Cedrela odorata*) used in the manufacture of cigar-boxes and boards of boats.

Very similar to the timbers of ordinary oaks are those of the true chestnuts, *Castanea vesca* of Europe and *C. dentata* of North America, but these lack wide medullary rays and consequently display no striking "silver grain."

Species of *Diospyros* growing in tropical Asia and Africa supply the black ebonies of commerce. The black of the heart-wood may be interrupted by patches of white (in Andaman marble-wood) or brown (in calamander wood). The Japanese and North American *persimmon* woods belong to species of *Diospyros*, and pieces of the latter have little or no black wood

The commercial timbers are produced by several species of European and North American species of elm (*Ulmus*). They generally have heart-woods lasting well in permanent contact with water; the water-pipes of London in olden times were often made of hollowed trunks of elms.

Australia is the world's centre for the growth of eucalyptus-trees, a number of which produce hard, heavy, strong timber of large dimensions, and include *jarrah, karri, tallow-wood,* and *tuart.*

Greenheart is a tropical South American wood, which is generally stated to be that of *Nectandra Rodiaei*, varies in colour from yellow-green to darker admixtures of colours. Resistant to shipworms it is used widely for piling in docks: for fishing rods it is pre-eminent.

Commercial hickory woods of good quality are produced by a number of species of *Hicoria* in the United States. These find much the same uses as ash, since they are tough, but being stiffer than ash they can be used for the shafts of golf-clubs.

The name mahogany is improperly given to a medley of woods which range from white to bluish red in colour and grow in various countries. The original mahogany was that of *Swietenia mahagoni* growing in the West Indies: this species together with the allied *S. macrophylla* growing on the mainland of Central America supply true American mahogany. These reddish-brown woods shrink and warp but little, are durable, light and polish readily to yield beautiful decorative effects. Any other woods named mahogany should share these characters. Such is the case with West African mahoganies produced by certain species of *Khaya* (belonging to the same family, Meliaceae, as *Swietenia*), which are indistinguishable by most people from the American mahogany. The West African "Gaboon mahogany" is a wood belonging to trees (or a tree) of an entirely different family, and is not a mahogany: neither are any of the so-called mahoganies of India, Australia, the United States and South America.

Maples, including the European sycamore, belong to the genus *Acer* and yield white firm woods that have a silvery sheen. North America supplies maples used in block-floorings and the beautiful bird's eye maple used in furniture.

True oak timbers are produced by species of *Quercus*, which is a genus not growing south of the equator, and the commercially important ones are European, North American and Japanese in origin The European timber is mainly derived from the wide-spread *Q. pedunculata* and *Q sessiflora*, and stands apart from the other commercial kinds in being the sole one that can be safely used alone in the construction of casks and barrels for the storage of beer, wines and spirits without causing deterioration of flavour of these Great Britain produces a unique type, termed "brown oak," which is used in the manufacture of panelling and furniture in Europe and North America. The European oak imported into England is known as Russian and as Austrian oak, when exported from Baltic ports and Fiume respectively North American commercial oak timbers are produced by a larger number of species of *Quercus* belonging to two groups, the "white" and "red oaks," which contrast in structure and uses

Genuine lustrous satinwoods in origin are respectively East Indian (*Chloroxylon Swietenia*) and West Indian (*Xanthoxylum*).

Teak timber is produced by *Tectona grandis* which yields commercial supplies only in the Indian Peninsula, Burma, Siam and Java. The valuable yellow to brown heart-wood is hard, strong, stiff and very durable; moreover, unlike oak, it does not attack iron. As the wood also "stands" well, it is excellently suited for use in window-sills, ships and flooring. The wood shows annual rings, and thus contrasts with such spurious teak timbers as "West African teak" (*Chlorophora*) and Indo-Malayan "eng or yang teak" (*Dipterocarpus*).

The two most important walnut timbers are those of *Juglans regia,* whose distribution stretches from England to northern India, and *J. nigra,* which is North American. The heart-wood of both species is brown, that of the former species is often traversed by brown lines, while that of the American is wholly of a blacker brown. Both woods are unrivalled for the manufacture of gun-stocks and are excellent furniture wood, as when it has been thoroughly seasoned and polished it shrinks and swells very

little. The wood has clearly marked annual rings and thus contrasts with two tropical spurious "walnuts," the East Indian (*Albizzia Lebbek*) and West African (*Lovoa Klaineana*). A third misnamed wood is known in Great Britain as "satin walnut" (also as "hazel-pine") and in the United States, its native country, as gum (sweet or red).

Confusion frequently arises in England as to the identities of several woods that are more or less white. From the United States there are exported to England several kinds of wood having that character. (1) One is named "canary whitewood" in Great Britain but "yellow poplar" in America: it is produced by the tulip-tree (*Liriodendron Tulipifera*), and ranges in colour from light yellow to iridescent blue. (2) In addition are woods produced by true poplar trees (*Populus*), which are named "cottonwoods" in the United States (3) Thirdly there are woods known in England as lime and in America as basswood, that are produced by lime-trees (*Tilia* spp.), which of course are very different from the limes (*Citrus*) producing the familiar juicy fruits.

BIBLIOGRAPHY.—Percy Groom, *Trees and their Life Histories* (London, 1907), a finely illustrated book, giving accounts of the natural histories, some of the diseases, and means of identification of a number of European, North American and other species of trees, mostly yielding commercial timbers; Alex. Howard, *Timbers of the World* (London, 1920), a comprehensive work dealing *seriatim* with the world's most important timbers of commerce mainly from the view-point of their properties, including appearances and uses, and geographical and botanical sources it also includes special articles on the conversion and preservation of timber, and on artificial seasoning; A Koehler, *The Properties and Uses of Wood* (New York and London, 1924), an excellent general account of the subject; H. D. Tiemann, *The Kiln Drying of Lumber* (Philadelphia and London, 1917), an authoritative and lucid exposition on the theory and practice of artificial seasoning of wood in kilns (P. GM)

TIMBER LINE, the altitudinal boundary of natural tree growth In any elevated area in low or middle latitudes the line is generally clearly marked, but its height is dependent not only on general but also on local climatic and soil conditions. (*See* SNOWLINE.)

TIMBER PRESERVATION. The art of protecting timber from decay or the ravages of insects is of very ancient origin. It is probable that the Egyptians, who were experts in the preservation of organic bodies, also preserved wood by artificial means. Pliny mentions that the ancients employed essential oils, such as oil of cedar, olive oil, oil of spikenard, or vinegar. An even more universal method was to char wood to protect it from decay, a well-known instance of which is the charred piles under-pinning the temple of Diana at Ephesus. The beginning of the 19th century saw the introduction of modern methods of injecting wood with either salt or oil solutions Later, a further impetus was given to wood preservation by the introduction of railways, requiring large quantities of wooden sleepers, and by the discovery of telegraphy, which necessitated large numbers of telegraph poles. There is at the present time an urgent need, other than that of direct monetary importance, for prolonging the life of timber, and that is to conserve the world's timber supply by every possible means, which includes, amongst others, the antiseptic treatment of timber. Antiseptic treatment was introduced into America about 1850, and gradually spread to most civilized countries of the world, though in India and Australia, where extremely durable timbers are available, such as teak and jarrah, the treatment of railway sleepers has only been undertaken in quite recent years.

Causes of Decay.—Timber may deteriorate from several causes; amongst the more common are decay due to fungi, the attack of insects and marine-borers, and mechanical defects such as abrasion, crushing, splitting or other types of fracture. One of the commonest forms of decay is known as "dry rot," produced by several species of fungi, of which the most important is *Merulius lachrymans.* The number of insects which attack wood is very great, but probably those which do most damage are the death watch beetle (*Xestobium rufo-villosum*), injurious to structural timber; the powder-post beetle (*Lyctus* sp.) and the common furniture beetle (*Anobium punctatum*), destructive to furniture. A number of marine molluscs (*Teredo,* the shipworm) and crustaceans (*Limnoria,* the gribble, and *Chelura*) are most destructive to wood construction in sea-water. In the tropics the greatest enemy to timber are the termites known as white ants

Antiseptics Used in Wood Preservation.—Antiseptics used in the preservation of wood may be divided into two broad classes, namely, oils and salts, of which the former are mostly derived from coal-tars, though wood-tar products and certain essential oils must be added to the list. The oils are in certain processes mixed with salts, as for instance in the Card process, while, recently, considerable attention has been paid to mixtures of coal-tar creosotes and earth oils Certain salts attracted attention as possible antiseptics for the treatment of timber, as early as 1705, when Homberg used mercuric chloride, although this salt is more commonly associated with Kyan, after whom the process is named. Of all salts which have been used in treating wood that which has best stood the test of time is chloride of zinc, discovered by Boucherie, but known as Burnettizing, after Sir William Burnett. Copper sulphate was used as long ago as 1840, but has since fallen out of favour; the most recent to be seriously considered are fluoride salts, which were first exhaustively tested by an Austrian engineer, named Malenkovic. Between 1904 and 1908 an entirely new process was brought out by Powell, which consisted in boiling timber in molasses, to which was added a small percentage of arsenic for use where white ants were prevalent.

It was Bethell who started on practical lines the treatment of wood with coal-tar products in 1838, though it is certain that the possibility of injecting these oils into timber was attempted before this date. Probably no name is better known in connection with timber preservation than that of Bethell, who used a product of coal-tar commercially known as creosote, which is at present by far the most popular antiseptic in use. It should here be noted that true creosote is a wood-tar product, though the word is now commonly and erroneously used for the coal-tar product. Coal-tar creosotes differ greatly in composition, depending on the quality of the tar and the coal from which they are produced, and various commercial grades are prepared to meet different requirements. For standard products the *British Engineering Standards Association's Specification,* No. 144/, 1921, dated Aug. 1921, should be consulted.

Methods of Treatment.—Before treatment all bark should be removed and the ends of the timber cleansed. It is important to note that the inner bark either stops or retards lateral penetration, which is one of the most difficult obstacles to be overcome. All processes, with the exception of the Boucherie and Powell processes, require that the timber should be seasoned. The degree of seasoning required will vary with the process, the class of timber to be treated and the use to which it is to be put. The moisture in wood occurs in the pores and cavities between the fibres and in the cell walls; the former being termed free-water and the latter sorbed water. As the timber seasons, the free-water is first given off until there remains from 25% to 30% by weight of the sorbed water. The moisture content should be reduced to below 20%, so that all the free, and part of the sorbed, moisture disappears, leaving the cavities free to take up the antiseptic.

The methods by which timber may be antiseptically treated fall under three heads, namely, the brush method, treatment in open tanks and treatment in closed cylinders under pressure.

By the open tank method the timber is immersed either in coal-tar creosote or a salt solution, in a tank which is heated by placing a fire beneath it, or preferably by means of steam coils. The antiseptic is gradually raised to a temperature of 90° C to 95° C, maintained at that temperature for a period dependent on the thickness of the material under treatment, and then allowed to cool down to atmospheric temperature. The heating period should, generally speaking, be maintained for an hour for every inch in thickness of the material. When the timber is heated in the solution it expands, and air is expelled from the cellular and intercellular spaces; as the timber cools that air is replaced by antiseptic. Fair penetration may be obtained by this process, which in pine-wood sleepers containing a moderate percentage of sapwood, amounts to approximately 5 lb. per cubic foot. This method of treating timber is applicable to cases where moderate

quantities of timber have to be dealt with. A process by which wood is treated with saccharine solutions, known as the Powell process, is carried out in open tanks; the timber is boiled in a diluted solution of sugar, to which a small percentage of arsenic is added for protection, in tropical countries, against the attacks of white ants The process consists in boiling green timber for several hours, the time varying according to the dimensions and species of wood under treatment It is then allowed to cool down and is placed in a drying chamber. This process has been successfully employed in Australia, while extensive tests carried out with Powellized sleepers on Indian railways give good results

Pressure Processes.—These are carried out in cylindrical retorts varying in size from 6 to 9 feet in diameter, and 30 to 160 feet in length, capable of withstanding a pressure of 200 lb per square inch, and fitted with doors at either one or both ends. Inside the cylinder are placed rails to take the trolleys on which the timber is loaded, and below the rails is inserted a system of steam pipes for heating the antiseptic solution, and in certain plants a steam spray line To the cylinder are attached pressure and vacuum pumps and in some cases air pumps. A second cylinder or storage tank is generally provided, which is generally placed above the pressure cylinder. Surrounding the treating plant is the timber yard, which is conveniently laid out with feeder lines to and from the treating cylinder. The Full-cell or Bethell process, which employs coal-tar creosote, consists in subjecting the seasoned timber to a pressure of 100 to 180 lb. for one or more hours, after which the oil is run off and the timber allowed to drip In some cases a vacuum is drawn for a short period, to hasten the removal of the coal-tar creosote left on the surface of the timber. Some operators when dealing with green timber, first subject it to a steaming period of several hours, and then draw a vacuum for one or two hours, in order partially to remove the free moisture in the wood, but this does not result in such satisfactory penetration as does the treatment of seasoned timber. Treatment by a full-cell process results in an absorption of from 7 to 15 lb. of coal-tar creosote per cubic foot.

The open-cell process may be carried out according to two different methods; one method was patented by C. B Lowry, by which the coal-tar creosote is run into the cylinder at a temperature of 200° F, and a pressure of from 180 to 200 lb. is applied, until no more oil can be forced into the timber, *i.e*, until the timber has been treated "to refusal." The pressure is then released, the oil run off, and a vacuum drawn, until the oil in the intercellular spaces has been removed; this oil may amount to 40% of the original absorption, leaving some 6 to 7 lb per cubic foot behind in the timber The other open-cell process, discovered by Rüping, aims at as deep a penetration as possible and at the same time economizes, recovering, as does the Lowry process, a portion of the oil originally introduced To carry out this process a second cylinder, capable of withstanding 100 lb. air pressure, is placed at a higher level than the treating cylinder The air-dried timber is placed in the treating cylinder and subjected to an air pressure of 60 to 80 lb per square inch. The high level cylinder is filled with the preservative to within a few inches of the top, and an equal air-pressure is applied to its upper surface The antiseptic is then allowed to flow by gravity from the upper to the lower cylinder, the air displaced in the latter being led into the former by a by-pass The two cylinders are then disconnected and the pressure in the treating cylinder is gradually raised to 150 lb. per square inch and held there until 10 to 12 lb per cubic foot have been absorbed. The pressure is then released and the oil run off; this results in a partial vacuum being set up, and allows the compressed air in the wood to expand and to force out the surplus oil.

A process invented by Card, for which a patent was granted in 1906, consists in treating timber with a mixture of 20% coal-tar creosote and an 80% solution of chloride of zinc, the strength of the latter being regulated so that ½ lb of dry salt be taken up per cubic foot. It is a full-cell process, the operation being similar to that of the Bethell process, except that the mixture is kept in emulsion by a powerful centrifugal pump which circulates it through a spray pipe.

THE TIMBER- OR GREY-WOLF

TIMBER-WOLF (*Canis occidentalis*), or grey wolf, an American species (*see* WOLF). The length of good specimens is about 64in., inclusive of the tail, and the range of colour is from black to white. Cattle ranchers and shepherds have established a war of extermination against this wolf and the coyote.

TIMBREL or **TABRET** (the *tof* of the ancient Hebrews, the *deff* of Islam, the *adufe* of the Moors of Spain), the principal musical instrument of percussion of the Israelites, identical with the modern tambourine. The tabret or timbrel was a favourite instrument of the women, and was used with dances, as by Miriam, to accompany songs of victory, or with the harp at banquets and processions; it was one of the instruments used by King David and his musicians when he danced before the Ark.

TIMBUKTU (Fr. Tombouctou), chief town of a district of the colony of French Sudan, French West Africa, 9 m. N. of the main stream of the Niger in 16° N and 5° W.

Timbuktu lies on a terrace formed by the southern scarp of the Sahara, about 800 ft. above sea-level, surrounded by sandy dunes covered with mimosas and other spiny trees. Timbuktu communicates with the Niger by a series of marigots or channels with alternating flow, which fill at flood time and empty themselves into the Niger when the dry season supervenes In January, the maximum period, the waters reach the walls of the town through the marigot from Kabara, which is the port of Timbuktu

Timbuktu has been described as "the meeting point of the camel and the canoe," "the port of the Sahara in the Sudan," and (more correctly) "the port of the Sudan in the Sahara" It was formerly a much larger place than it was found to be at the time of its occupation by the French in 1893–1894. Extensive ruins exist north and west of the present town The great mosque which at one time stood in the centre of the town now lies near the western outskirts, where its high but unsightly earth tower forms a striking landmark The mosque of Sidi Yahia (in the centre of the town) and that of Sankoré in the north-east also possess prominent towers Whereas in 1895 the town was little more than a vast ruin, under French protection the inhabitants, relieved from the fear of Tuareg oppression, set about repairing and rebuilding their houses; new streets were built; European schools, churches and other establishments were opened. But Timbuktu has not yet recovered; the population is only 7,000 with a majority of Sonrhai; at the time of the commercial transactions from March to June, the population reaches 25,000

The industries of Timbuktu—cotton-weaving, earthenware, leather-work and embroidery—are of subordinate importance, and the great bulk of the people are occupied exclusively with trade. The whole traffic of the surrounding lands converges on Timbuktu, two great caravans of 3,000 or 4,000 camels are yearly charged with salt from the Taudeni district, salt being an article which the Niger countries lack.

Timbuktu, which possesses some valuable Arabic manuscripts —notably the *Tarik es-Sudan,* a 17th-century history of the Sudan written by Abderrahman Sadi of Timbuktu—and is a centre of Moslem teaching, is a converging point of the chief west Sudanese and Saharan races—Arabs or Arabized Berbers to the west; Sonrhaï in the immediate vicinity, and thence south-eastwards along the Niger; Ireghenaten or "mixed" Tuareg southwards across the Niger as far as the Hombori Hills and in the fertile Libbako plains beyond them; Fula, Mandingos, and Bambara in and about the city; and Imoshagh (Tuareg) belonging to the Awellimiden confederation mainly to the north and east.

The local administration—preserved under French rule—is in the hands of an hereditary *kahia,* a kind of mayor, descended from one of the Ruma families. (A. BE.)

History.—The history of Timbuktu is intimately connected with that of the city of Jenné and the Songhoi empire. The Songhoi (*q.v.*) are a negro race reported to have come to the Niger countries from the Nile valley. In the 8th century they made themselves masters of a considerable tract of country within the bend of the Niger, and built the city of Gao (*q v*), 200m. in a direct line S S E of Timbuktu, making it their capital In the 11th century they were converted to Islam. Besides Gao, the Songhoi founded Jenné (*q v*), which early attained considerable commercial importance Meanwhile (11th century) a settlement had been made at Timbuktu by Tuareg Perceiving the advantages for trade with the north offered by this desert rendezvous, the merchants of Jenné sent agents thither (12th century), and Timbuktu shortly afterwards became known to the inhabitants of the Sahara and Barbary as an excellent market for their goods, and also for the purchase of the many commodities of the western Sudan In the 12th or 13th century Timbuktu fell under the power of the Mandingo kings of Melle or Mali, a country lying west and south of Jenné. Its fame as a mart for gold and salt spread to Europe, "Timboutch" being marked on a Catalan map dated 1373 In 1353 it had been visited by the famous traveller Ibn Batuta In 1434 the Tuareg made themselves masters of the city, which in 1469 was captured by the Songhoi king Sunni Ali It was at this time (1470) that Timbuktu was visited by an Italian, Beneditto Dei In the days of Sunni's successor Askia (1494–1529) the Songhoi empire reached its highest development, and Timbuktu rose to great splendour The "university" of Sankoré became a chief centre of Mohammedan culture for the peoples of the western Sudan

The riches of Timbuktu excited the cupidity of El Mansur, sultan of Morocco, who, in 1590, sent an army across the Sahara under an "Andalusian" Moor (that is, a Moor descended from those expelled from Spain), which captured Timbuktu (1591) and completely broke up the Songhoi empire For about 20 years after the conquest the pasha who ruled at Timbuktu was nominated from Morocco, but the distance of the Niger countries from Marrakesh enabled this vast viceroyalty to throw off all allegiance to the sultan of Morocco The Niger Moors, known as *Rumas* after El Mansur's musketeers, quarrelled continually among themselves, and oppressed the negro tribes By the end of the 18th century two hundred years of oppression had reduced Timbuktu to comparative desolation and poverty By this time the whole country was in a state of anarchy, and in 1800 the Tuareg swooped down from the desert and captured the place They were in turn (1813) dispossessed by the Fula, who in 1840 gave place to the Tukulor (*See* SENEGAL, *History*)

At this period European interest in the region had revived Maj. Gordon Laing, who had reached Timbuktu from Tripoli in 1826, had been murdered by order of the Fula; but René Caillié, coming from the south, had been in the city in 1828 and had returned in safety. Heinrich Barth, an officially accredited representative of the British Government, reached Timbuktu from the Central Sahara in 1853 and some effort was then made to bring the place under British influence. El Backay (Bakhai), the sheikh who received Barth, gave him letters professing much friendship for the British, and in a letter to El Backay, dated April 15, 1859, Lord Clarendon, secretary of State for foreign affairs, said that "the friendship binding us shall not diminish through the centuries" and "as our Government is very powerful we will protect your people who turn to us" A nephew of El Backay's went to Tripoli, saw the British consul and was told that a British steamer was ascending the Niger and that the Government had recommended those on board "to make every effort" to reach Timbuktu. But no one from the lower Niger reached El Backay, whose influence appears to have declined after Barth's visit; and no further attempt appears to have been made by the British to keep in touch with Timbuktu. Indeed, between Barth's visit and the French occupation only one white man, Oskar Lenz, in 1880, reached Timbuktu and he crossed the desert from Morocco. It was in the following year, 1881, that the French, thrusting forward from Senegal, began the conquest of the countries of the Niger bend When they reached Timbuktu in December 1893 they found that the town had again fallen beneath the rule of the Tuareg. The townsfolk, indeed, from the time of the decay of the Ruma power being at the mercy of all comers, were content to pay tribute to each in turn and sometimes to more than one simultaneously, for which they indemnified themselves by peaceful intervals of trade whenever the land routes were open and the Niger clear of pirates But at times even the short tract separating the town from Kabara was so beset with marauders that it bore the ominous name of "Ur-immandess," that is, "He (God) hears not." Little wonder then that the townsfolk freely opened their gates to the French as soon as Lieut Boiteux reached Kabara in command of a small flotilla

The occupation of the town, against orders, was a daring exploit of a handful of marines The force which "garrisoned" Timbuktu consisted of seven Europeans and twelve Senegalese The somewhat larger body left with the gunboats was attacked by the Tuareg (Dec 28) and suffered severely Col T P E Bonnier, who was at Mopti, 200m to the south-west, marched to the relief of Boiteux and entered Timbuktu without opposition on Jan 10, 1894 He then set out with about 100 men to chastise the nomads. In the night of Jan 14–15 his camp was surprised and the colonel and nearly all his men perished The enemy did not follow up their victory, and within a short period French rule was firmly established in Timbuktu In 1903 the French authorities placed commemorative tablets on the houses occupied by the four travellers, Laing, Barth, Caillié and Lenz, during their stay in Timbuktu Under French rule the town has regained a measure of importance

TIMBY, THEODORE RUGGLES (1819–1909), American inventor, was born on April 5, 1819, in Dover, New York His most noted invention was the revolving turret, which he first conceived in 1841 He first constructed a small model and displayed it in Washington Later he built a steam-propelled model in Syracuse, N Y (1842) This he exhibited in the city hall, New York, where it was inspected by President Tyler and his cabinet In 1843 he obtained a caveat from the patent office During the Civil War, when the "Merrimac" had been constructed with heavy iron armour by the Confederate Government, it became evident that a new type of ship must be built to compete with it. At this juncture John Ericsson came forward with plans for a floating battery. These plans were presented to the naval department and promptly accepted Immediately an organization known as the "Battery Associates' was formed to build armoured ships according to Ericsson's plans When Timby heard of this Government contract, he presented the caveat for his patent on the revolving turret, which was to be the main feature of Ericsson's floating battery The Battery Associates, recognizing Timby's claim, agreed to pay him $5,000 on each turret built Soon afterwards, with Ericsson as engineer of the design and construction, the battleship "Monitor" was completed When she met the "Merrimac" and gained her famous victory, Ericsson was given general recognition as the inventor of the revolving turret No serious efforts were made to correct the misapprehension until Timby's death. From 1861 to 1891, Timby invented and patented, at home and abroad, a system of coast defences, such as the sighting and firing of heavy guns by electricity; the tower and shield; the cordon across a channel; the planetary and subterranean systems, and numerous modifications of the turret system He died in Brooklyn, N Y, on Nov. 9, 1909.

See the *Memorial to the 57th Congress for Recognition of T R Timby* by the Patriotic League of the Revolution (1902), and the *Memorial to T. R. Timby* (1911) by the Timby Memorial Trust

TIME, the general term for the experience of duration. For time in its psychological sense *see* SPACE-TIME; for time in music, *see* below, for the methods of reckoning time *see* CALENDAR; DAY; MONTH; and the articles TIME MEASUREMENT and TIME, STANDARD.

In Music, time is a term signifying the number of beats in a measure or bar. When there is an even number of beats, as 2 or 4, the music is said to be in common or duple time. When there are 3 beats in a measure it is said to be in triple time. Further, when the beats are of the value of an aliquot part of a semibreve the time is termed simple. Thus four crotchets, or their equivalents, in a measure constitute simple common time, while three crotchets, or their equivalents, constitute simple triple time. When, on the other hand, the beats are of the value of dotted notes, and therefore not aliquot parts of a semibreve, the time is termed compound. Thus four dotted crotchets in a measure constitute compound common time, while three dotted crotchets in a measure constitute compound triple time. The time of a composition is indicated at the beginning by what is termed the "time signature," in the shape of a fraction specifying the number of aliquot parts of a semibreve which each measure contains, as $\frac{4}{4}$ (=4 crotchets) or $\frac{3}{8}$ (=3 quavers).

TIME, STANDARD. In an isolated community clocks and watches would naturally be set to the local mean time (*see* TIME MEASUREMENT), and before the period of railway communication the different towns as a rule kept local time

The need for a more systematic plan of standard times was chiefly felt in America Whilst the railways in England were run by Greenwich time, and the railways in France by Paris time, it was not to be expected that railway systems in the middle and western States would adopt Washington time, differing by several hours from the local time of the region which they served. Hence each railway had its own time, or, in the case of the longer lines, several different time zones, and great confusion arose at overlapping points. The remedy of this state of things is due to Sandford Fleming, a Scotch Canadian, who in 1878 brought forward the plan of adopting for the whole earth 24 standard meridians 15° apart in longitude, starting from Greenwich. These meridians were to be the centres of 24 time zones, in each zone the time adopted would be uniform, and it would change by one hour in passing from one zone to the next After long discussion the railway managers of the United States and Canada decided to adopt the system

Zone time based on the Greenwich meridian is now adopted almost everywhere except in Holland. In most countries the time differs by an integral number of hours from Greenwich time, in accordance with the original plan; but in some of the British dominions, also in Venezuela and Uruguay, a compromise involving half-hour differences has been adopted. European countries (except Holland) are ranged in three groups, keeping respectively Greenwich time, mid-European time (one hour fast), east European time (two hours fast). In the United States and Canada there are five time-zones, called Atlantic, Eastern, Central, Mountain, Pacific respectively 4, 5, 6, 7, 8 hours slow on Greenwich time. A full list of standard times of the different countries, as well as of those keeping non-standard time is published year by year in the *Nautical Almanac.*

In the summer months a number of countries advance their time by one hour, or, as we may put it, adopt the time of the next zone to the east Thus legal time in Britain is Greenwich time in winter and mid-European time in summer This plan was first brought into practice in Germany early in 1916, closely followed by Austria, Holland, Denmark and Norway. These countries, except Holland, have since abandoned it. In England a movement in favour of this plan of "daylight saving" had existed for some years, led by William Willett; a bill to introduce it passed the second reading in 1908, and again in 1909. Under pressure of war economy and persuaded by the example of Germany, parliament adopted the measure in May 1916. The advantage of *summer time,* as it is called, depends very much on the latitude, and it is scarcely suitable for more northerly or southerly countries; it is rather unpopular in agricultural communities. In Britain, France, Belgium and Holland, where it continues to be used, it is strongly supported.

The advantage of adopting a continuous reckoning of the hours from 0 to 24 instead of using the divisions A.M. and P.M. is obvious, and this reckoning is now in general use in some countries. For civil purposes the reckoning starts from midnight. In astronomy, however, there exists a reckoning, called astronomical time, beginning from noon; thus March 10 15^h astronomical time is 3 A.M. on March 11 by civil time. Up to 1925 astronomical reckoning was used in the national ephemerides; but it was found that this caused some difficulty and confusion to seamen, and an international agreement was made to adopt civil reckoning in the ephemerides from 1925 onwards. It was recognized that this would probably lead to the abandonment (total or partial) of the astronomical reckoning by astronomers themselves. Unfortunately, the decision was interpreted in some quarters as implying a change of nomenclature—that "astronomical time" was henceforth to mean civil time—a purposeless and confusing change for which there is no authoritative sanction. The most prominent offender was the British Admiralty, who caused in this way a change in the use of the designation G.M.T. (Greenwich Mean Time) in the *Nautical Almanac* without authority. The situation was considered by the International Astronomical Union in 1928, who advised astronomers not to use the letters G.M.T. in any sense for the present The terms Greenwich Civil Time (G.C.T.), Weltzeit (W.Z.) and Universal Time (U.T.) denote time measured from Greenwich mean midnight and are not ambiguous. For time reckoned from mean noon the expression Greenwich Mean Astronomical Time (G.M.A.T.) is the most satisfactory. The Julian day is counted from Greenwich mean noon as heretofore.

(A. S. E.)

TIME MEASUREMENT. The problem of the measurement of time demands a reference to its philosophical foundation, if it is to be viewed otherwise than as an empiric treatment of a practical necessity. Without touching the contention of relativists that time is in a certain sense merely a fourth dimension added to space, we may take it that to any individual it appears different and separate from his space, and is simpler than space to treat because it has merely one dimension. The difficulty arises precisely because of this fact, that it is fundamental and there is nothing similar or simpler to compare it with. Duration, permanence, existence even, all presuppose the lapse of time and therefore some means for its detection, or, what is the same thing, some primitive measure of it. The fact upon which all these ideas are based is the possibility of repetition of experience. When experiences are repeated, closely enough, we associate them with the ideas of things and reality. Such appears to be the psychological history of the construction of our world. We look then for the measurement of time to some process with recognizable repetitions, which may be counted. This replaces the impalpable idea of duration by counted steps and thus brings time into the class of measured quantities. Pulse beats, the alternations of day and night, the periods associated with definite spectral lines are instances of natural processes that have actually served this purpose, besides artificial instruments such as the balance watch and the pendulum clock; but to isolate the essential features we may idealize an instrument for the measurement of time as a gyroscope (A) mounted without friction inside a case (B), which may or may not itself rotate, and is held, friction free, at the common axis (O); or more abstractly still we may imagine two particles A, B, revolving at different angular speeds about a common centre O. Each new passage of A past B is a repetition, giving a countable step of time. This may be used for measurement of time precisely as a pair of compasses is used for measuring space. If we do not know that the revolution of A with respect to B is constant, that corresponds to the use of a pair of compasses not known to be stiff at the joint; the measure can still be made for what it is worth and may be the only one possible. If the lapse of time measured falls between two integral counts, we have the problem of subdividing the standard unit by constructing a smaller one which is standardized by comparing it with the standard. No new problem, theoretical or practical, is introduced thereby, and

known methods are applicable to its treatment. The parallel and contrast between the measurement of time and of one dimensional space may be probed further. Measurement of the latter is effected practically through the construction of an (arbitrary) standard yard or metre, from which copies are taken and comparisons made. If a copy A′ B′ is compared with the standard A B, the mark A′ is seen to agree with the mark A, at a particular time, and the mark B′ to agree with the mark B, *at a different time,* the difference being the time taken by the observer to travel from A to B. If we introduce mirrors at A′, B′, so that the congruences may be observed simultaneously, this does not abolish the time difference but only reduces it by making light the traveller. The difference is essential in kind. Now consider the standard for time measurement, a gyroscope in which there is a mark A, rotating within a case on which there is a mark B. Compare this with a copy A′, B′. The cases B, B′ may be in rotation, and the marks B, B′ cannot be brought into permanent coincidence. Thus the step of time between two passages of A′ across B′ may be compared with that occupied between two passages of A across B, only with an allowance for the time taken for a signal to pass across the space between B and B′. If B and B′ are the same, as they may be if both are effectively the sphere of stars, then the allowance for the passage of the signal is abolished, and the comparison of the two standards of time is more perfect than that of two standards of distance; the reason for this is that for the two ends of a standard of space we cannot have the same time, but for two ends of a standard of time we can have the same point of space. We can pass to and fro in space but not in time

If two points A_1, A_2 pass across B at an interval which is an ascertained fraction of the period of A_1, with respect to B, then, *knowing nothing else about them,* an hypothesis is required, in order to tell from this observation what fraction of four right-angles A_1 A_2 subtends at O. If A_1, A_2 rotate as if rigid and uniformly, the fraction is the same as the fraction of the period If they rotate independently, say under the action of the same acceleration to the centre O, no conclusion can be drawn without further data. Generally it must be remembered that in order to define the motion, *e.g.,* in its relation to the right angle, it would be requisite to define first the metric of the space in which it takes place in addition to assigning its own "law" But in the absence of special statement, rigidity and uniform rotation will be presupposed, making the time interval and the angle A_1OA_2 equivalent measures

Units of Time.—The practical standard for measuring time is the rotation of the earth, and is very close to the ideal one. If we take the earth as the body A and the sphere of stars as the body B enclosing it, their relative period gives an observable unit of time, the so-named sidereal day. It differs from the mean solar day employed in civil reckoning in a way defined below The stars are, of course, not quite fixed with respect to one another, but as they are their own standard of reference, their mean is fixed, and there appears to be no meaning to be attached to the idea that it is in motion, especially if we allow in the case of each star for all systematic apparent motions such as those due to the earth and the sun, and the individual motions peculiar to each star, leaving only an accidental residuum to cancel itself out. Taking then the mean of the sphere of stars as the zero, and supposing the local Euclidean geometry continued outwards to mark the positions of the stars, the rotation of the earth with respect to the sphere of stars becomes an absolute quantity, that is to say, a quantity completely defined. In describing it so, some practical qualifications are subsumed. Thus, small allowances varying in different latitudes and different times of the day and year require to be made on account of the finite velocity of light by which the stars are recognized. Also, it is convenient to measure from a slowly moving zero, the equinox, which is easier to identify than the mean of the stars. Reference is made to these and others below. The principle is unchanged.

A smaller unit than the day is provided by the pendulum clock, of which one beat or a semi-oscillation equals a second, of which there are $24 \times 60 \times 60 = 86{,}400$ in the day. Much loose writing is found in relativist literature about "clocks," as though the clock were a simple instrument which it was unnecessary to define further. Such is not the case. We may regard the clock as a machine to imitate the rotation of the earth. If the 24-hours dial of a sidereal clock is imagined as set in a plane parallel to the equator, with the right side up, its index will continue to point always to the same star. The theory of the clock is complicated and has nothing primitive about it. It indicates, however, that the construction of a clock that shall go uniformly is possible; but the practical execution of clocks, though enormously improved recently, is not perfect. The going is liable to derangement from a number of causes, not all of which are clear. In short, the clock is in the position of a secondary standard only, which must be adjusted to the primary standard, viz, the sidereal day or observed rotation of the stars. The same remarks apply with increased force to portable watches and the marine chronometer, in which the beats are given by a balance wheel actuated by a spiral spring. The method by which the clock is adjusted to the rotation of the earth is described below. To subdivide the second, given by the beat of the clock, various devices are employed which are described more particularly in the article CHRONOGRAPH. In principle, they all rely upon converting time measures into space measures, by introducing a machinery that shall move a recording paper at a sufficiently uniform speed, making the clock mark seconds upon this, or, alternatively, making a tuning fork or other rapid vibrator impress closer marks, and subdividing the distance between the marks by any device suitable for space measurement. When we go beyond times which the chronograph can record, we have passed out of the region of actually countable steps of time

For a larger measure than the sidereal day, we turn to the year. The year can only be defined precisely by means of a curiously elaborate theory. The year being the period of the revolution of the earth about the sun, we must define its motion and the point to which it returns Since the motion is perturbed by the moon and the other planets, the orbit does not repeat itself, and any specification has no more than an "instantaneous" value at an assigned epoch. The process is to form a "theory of the sun," assigning its motion, for we may just as well contemplate geometrically a motion of the sun round the earth, as of the earth round the sun. To do this, all the observations of the sun's position are assembled, over the whole period of time for which they can be considered sufficiently exact, and the orbit is determined of a character assigned by theory, and agreeing with the observations as well as they allow over the whole period. The outcome is an ellipse of changing shape in a changing plane. The changes of course are small and slow, but by no means negligible. The mean motion with respect to the stars may, however, be taken as unchanged, and this defines the length of the *sidereal year.* But as remarked elsewhere, a return relative to the stars is not convenient to identify It is more convenient to count from the equinox, or point where the equator intersects the sun's path A return to this point corresponds also with a return of the seasons. Hence we define the *tropical year,* which is slightly shorter than the other because the equinox is in regressive motion.

From the theory of the sun comes also the definition of a derivative but indispensable measure, viz, *mean solar time.* The mean solar day is the mean period of rotation of the earth with respect to the sun The sidereal day is the period of rotation of the earth with respect to the equinox. If the sun makes a circuit of its orbit starting from the equinox, in a tropical year, the earth will have rotated just one time more with respect to the equinox than with respect to the sun in that period The tropical year is found to contain 366·2422 sidereal days Hence it contains 365·2422 mean solar days, and we have two parallel sets of units, days, hours, minutes and seconds, in the ratio of $1{\cdot}002738 : 1$, or $1 : 1 - {\cdot}002730$, the solar unit being the greater. Moreover, the mean solar day starts at a different point from the sidereal day. The latter starts when the equinox is on the meridian. The former starts when an artificially defined "mean sun" is on the meridian. The "mean sun" is an imaginary body defined for the purpose of keeping time, in such a way that it moves in the equator in agreement with the apparent sun's mean motion in the ecliptic. It is the transit of this body across the meridian of Greenwich that gives

the zero for "Greenwich mean time." As, of course, the "mean sun" cannot be observed, its reputed place with respect to the stars is calculated from the *theory of the sun*, in advance, in the ephemerides, and this permits us to observe other stars instead of it and to deduce the moment of its transit. By these means any observatory, of known longitude, constructs for itself "Greenwich mean time" from its own observations. In respect to the measurement of time the relations of the year with the system of mean time are more prominent than its use as a major unit of time In the latter connection it belongs to the subjects of the CALENDAR and CHRONOLOGY

For astronomical purposes and for long measures of time the Julian day is to be preferred to the year, because it avoids all irregularities of chronology The Julian day is simply the ordinal count of mean solar days, commencing at Greenwich noon. The number for 1925, Jan 1, mean noon is 2,424,152, following the system of Joseph Scaliger, who devised it and introduced it into chronology The number for the beginning of any other year may be derived from this, but is tabulated also in the *Nautical Almanac*, and elsewhere

Rotation of the Earth.—The rotating earth is the prime time-keeper and can be readily idealized into a perfect time-keeper. It is therefore desirable to examine critically how closely it approaches an absolute standard It might be supposed that the links were few and easily dealt with Such is not the case They are numerous, and a fairly full outline of the treatment must suffice, referring for detail to the sources.

Let the position of the earth be defined by its principal axe of inertia (OC,OA,OB). If for the moment we suppose the earth rigid, these will be fixed in its body and evidently one may be called its polar axis (OC), while the other two (OA,OB) define the equator where they mark determinate longitudes. The instantaneous motion of the earth may be defined in a simple manner with respect to these axes, namely if $A'B'C'$ are their positions after an interval δt, $A'B'C'$ may be derived from ABC by rotations $\omega_1\delta t$, $\omega_2\delta t$, $\omega_3\delta t$ about the axes OA, OB, OC. It is less simple to connect ABC, the position at the time considered, with their position $A_0B_0C_0$ at an assigned moment or "epoch" It is done by means of the so-named Eulerian angles, θ, ϕ, ψ where $\theta=CC'$, $\phi=A_0C_0C$, $\psi=180°-C_0CA$ These angles serve also to express ω_1, ω_2, ω_3, viz.:

$$\omega_1 = \dot{\theta}\sin\psi-\dot{\phi}\sin\theta\cos\psi,$$
$$\omega_2 = \dot{\theta}\cos\psi+\dot{\phi}\sin\theta\sin\psi,$$
$$\omega_3 = \dot{\psi}+\dot{\phi}\cos\theta$$

Further, by Euler's well-known theory of the rotation of a rigid body, ω_1, ω_2, ω_3 are given by the equations

$$A\dot{\omega}_1-(B-C)\omega_2\omega_3 = L, \qquad B\dot{\omega}_2-(C-A)\omega_3\omega_1 = M,$$
$$C\dot{\omega}_3-(A-B)\omega_1\omega_2 = N,$$

where A, B, C stand for the principal moments of inertia and L, M, N are the couples applied to the body about the principal axes. In the case of the earth we have very approximately, at least, symmetry about the polar axis, and the main rotation taking place about the same axis. Hence $A\backsim B$, $N\backsim O$, and ω_1, ω_2 are small. From the third equation, therefore $\omega_3=n$, a constant, and the equations for ω_1, ω_2 become $A\dot{\omega}_1+(C-A)n\omega_2=L$, $A\dot{\omega}_2-(C-A)n\omega_1=M$ The solution of these two consists of a free oscillation of arbitrary amplitude and phase with period $\frac{2\pi A}{(C-A)n}$, supplemented by any particular integral of the equations. Leave aside for the moment the free oscillation or "complementary function," and direct attention to the particular integral. For simplicity consider first the sun alone. By differential attraction on the protuberant parts of the earth in the neighbourhood of the equator the sun produces a couple, say P, applied to the earth's body, the axis of which is in the equator and directed to a point q, perpendicular to the plane through the polar axis C and the position of the sun S. This couple is a maximum at either solstice and vanishes when the sun is at either equinox. It is easy to see that it does not change sign when the sun crosses the equator. The values of the components L, M are then $L=P\sin(\odot-nt)$, $M=-P\cos(\odot-nt)$, where $\odot$ stands for the distance of the sun from the origin, measured along the equator. Now the equations for ω_1, ω_2 may be written

$$A(\dot{\omega}_1-n\omega_2)+(Cn\omega_2-L)=O,\quad A(\dot{\omega}_2+n\omega_1)-(Cn\omega_1-M)=O,$$

and the sun's position, and therefore P and $\odot$, change slowly compared with nt. Hence it may be seen that an approximate solution is

$$\omega_1=\frac{-M}{Cn}=+\frac{P\cos(\odot-nt)}{Cn},\ \omega_2=+\frac{L}{Cn}=+\frac{P\sin(\odot-nt)}{Cn},$$

which actually suffices for all purposes. The interpretation of this solution is that the pole C is at any moment turning in the positive sense with angular velocity P/Cn about the point s where CS meets the equator. Therefore the actual direction of the motion of C varies over two right angles, but the mean effect is a displacement of the north pole towards the vernal equinox, or what is the same thing, a regression of the equinoxes along the ecliptic. Besides its mean value, P contains also a reference to the actual positions of the sun and moon Hence all the inequalities that are required to specify their positions figure as periodical inequalities in ω_1, ω_2, in special degree those of a more permanent character, such as the position of the node of the moon's orbit on the ecliptic, which will evidently affect the value of the couple contributed by the moon All these inequalities combined constitute the *nutation*, an oscillation of the node of the equator upon the ecliptic, distinguishing at any date the *true* equinox from the *mean* equinox.

Since the motion of the equinox enters into every observation of position, other than merely differential ones, its determination is of the highest importance It is an intersection of the equator with the ecliptic or plane of the earth's annual motion round the sun This itself is in motion since the earth is perturbed by the other planets, but the motion may be calculated and allowed for It is, however, essential first to construct the "theory of the sun," already referred to, based upon a combination of all trustworthy observations of the position of the sun with respect to the fixed stars, and for the present object especial attention must be given to the two places in each year where the sun crosses the equator This connects the equinoxes with the stars which can be observed with the sun, for the most part a small number of the brighter stars, and therefore not characteristic of the whole. But they again may be connected with a larger mass of fainter stars, and so on, gradually approximating to a reference to the mean of the whole body of stars which it is agreed to treat as fixed As remarked above, it is from actual determination of the position of the equinox at different epochs that the period of the precession is deduced It is a matter of astronomical convenience to take the sidereal day, not from a revolution with respect to the body of stars, but with respect to the true equinox Hence the "sidereal day" as employed is not even of constant length, to reduce it to constant length we must remove from it the *nutation* which has been incorporated in it. The chief amount is an 18-year fluctuation, running for half the period in one direction and half in the other and dislocating the proper zero of the day by rather more than $\pm$1sec at maximum.

Return now to the question of a possible free oscillation of the axis of rotation of the earth, with respect to axes fixed in its body. We have so far supposed the earth rigid; but the earth, though very stiff in its main body, is not rigid. If it were rigid and if we suppose the actual axis of rotation to depart slightly from the principal axis of greatest inertia, it follows from the foregoing equations of motion that the axis of rotation would describe in the body a circle about the axis of inertia in a period $\frac{2\pi A}{n(C-A)}$ days, which the ascertained period of the precession shows to be about 305 days No such motion exists, whence for a long time it was falsely concluded that the two axes coincided so closely that observation could not separate them. This is not the case. Observations by F. Küstner, extended by S. C. Chandler, and now conducted internationally at a number of suitably placed

observatories, show that the axis about which the earth rotates moves around its mean position, at a distance of some 30ft. or less (0″.3), in a complicated curve, which can be analysed into two main components, one with a period of about 432 days, and the other one year. Both are therefore greater than the period for a rigid earth. It was pointed out by S. Newcomb that the proper interpretation is found in a slight yielding of the body under rotational stress, such as would accord with the estimated rigidity, viz, a little greater than that of steel. The longer period probably refers to this cause. A period of a year might easily be furnished by some seasonal effect.

Change of Length of the Day.—The foregoing has assumed that the couple N, the resolved part of the whole couple about the polar axis, is zero, or say that its mean value is zero, which implies that the rotation period for the earth must be constant But reasons are known to be in operation that may change it Thus if the body of the earth had gradually shrunk, as pretty certainly it must have done, the coefficient C would have diminished, and the angular momentum remaining unaltered, the angular velocity would have increased On the other side, the tides which in their phases generally follow the moon by a time that is fixed at any place, move in the same sense as the earth rotates, but much more slowly, so that they furnish a species of friction clutch or brake upon the earth and must slow down its rotation. A more general consideration of the earth-moon system and their secular changes of relative distance and relative motion shows that the slowing effect is divided between the earth's rotation and the moon's mean motion, but does not alter this consideration Hence it is very unlikely that the day, which we have used as a standard, is really constant The only tests we can apply to it are the other circulating bodies, the moon, Jupiter's satellites, the sun, the planets Of these the moon is the most favourable It moves much more slowly than the inner satellites of Jupiter, but its theory though complicated accords much more closely with observation Now there is another theoretical cause for secular acceleration in the moon's motion, but the theoretical value does not accord with the observational value That the difference is really to be ascribed to a lengthening of the day is indicated by tracing a proportionately smaller unexplained secular movement in the sun and residuals from the planets Venus and Mercury, all of which are in general agreement with the unexplained residues from the moon

The two causes of tidal friction and bodily changes in the earth affect in different degree the apparent accelerations of the moon. and the sun and planets This permits us to determine separately the two effects by fitting their joint outcome to the observed residues requiring explanation in both cases These residues are remarkable In place of a smooth curve of regular progression, they correspond very closely to a broken series of straight lines, which would mean sudden changes of increase or decrease of the length of the day at definite dates Thus in 1897 there was a sharp increase of the length by about ·004sec. and in 1918 an equally sharp decrease by the same amount The portion of these changes that must be attributed to tidal friction seems to accord numerically with what can be calculated The loss of energy takes place almost entirely in the shallow seas, such as the Irish Sea, where turbulent motion ensues and, so to speak, the energy of the tide is trapped As regards the other constituent, it is a different matter If the whole earth contracted proportionately, a decrease in the length of the day of the amounts mentioned above, would entail a shrinkage of half a foot in the radius over all the surface. This seems very improbable, and still more is the change that would account for the increase of the day in 1897.

The outcome of this criticism is that as far as astronomy is concerned, uniform duration is an abstraction, an idea; we cannot find any standard time-keeper that can be called absolute or even uniform. It is perhaps improbable that one should be found. The atom is a more likely place to look for an invariable standard. But this, too, may be a delusion. Atomic motions are certainly not less complicated than planetary motions In any case, their periods, of the order of 10^{-15}sec., are too small a standard

Practical Determination of Time.—Coming to the actual determination of time, we have a similar sequence of a direct method, simple and at first sight complete in theory, but requiring to be overlaid in practice with very numerous corrections in order to bring execution near to the idea As already pointed out, the clock is a secondary standard, which must be adjusted in subordination to observations of the earth's rotation The astronomical observation is thus often described as "finding the error of the clock" The astronomical observation, where any accuracy is aimed at, is always that of sidereal time. The beginning of the day at any place is the transit of the true equinox across the meridian Hence, as already remarked, it is affected by nutation The equinox itself cannot be observed, being merely the intersection of two abstract lines upon the sky; but by a very long chain of observations, going back continuously to Hipparchus 150 B C., and earlier, the relative spacing on the sky of all the lucid stars, and a great many more, has been determined with continually increasing accuracy, together with the "proper motion" belonging to each Relative to this mass of material the position of the equator and ecliptic are assigned, or what comes to the same thing, the coordinates of each star are given relative to the equinox and equator A collection of this kind is called a *star catalogue.* Star catalogues are of various grades. As far as measurement of time goes we need only consider the *fundamental catalogues,* which are based on an elaborate critique of all the material, and of which the latest example is Boss's *Preliminary General Catalogue of 6,188 Stars; Epoch 1900* The places of the stars given in such a catalogue cannot be used directly. They are "mean places at the epoch," and require correction for (1) proper motion in the interval, (2) precession, (3) nutation, (4) aberration, (5) parallax where sensible, (6) refraction, before the data will accord with the true or apparent place on the day and at the place considered As a rule these numerous and troublesome corrections (excepting the last) are computed and applied in the *Nautical Almanac* or other national ephemeris Imagining then the whole heavens to rotate in a piece about the polar axis, if we could observe correctly the passage of a single star across the meridian of the place and compare it with the time registered by the clock, we should have determined the error of the latter This, however, again requires several precautions In the first place, the meridian must be marked, by an instrument that can survey all parts of it Such an instrument must turn (1) at right angles to an axis that is set, (2) horizontally, and (3) due east and west. We must define what line in the instrument is to be perpendicular to the axis In a telescope this can be done with great precision But the three geometrical conditions can only be achieved imperfectly, and the only way to find whether they are achieved or not, is to study the way that faults in respect to them would affect the observation, and then to make a set of observations expressly to find the faults. Further, no matter with what care and solidity the instrument is built, it cannot be trusted to keep the same values for its faults or errors from one night to the next, nor even, with changing temperature, throughout a single night This complicates the question very much, for these observations are themselves fallible in very much the same degree as the direct determinations of the time of transit of a star. In particular, the determination of the level of the axis has proved the source of erratic variations in "clock error" which have certainly nothing to do with the clocks Yet reference to the level in some form is indispensable In the *transit circle* at an observatory, level error is usually found by turning the telescope downwards to a bath of mercury, which supplies a mirror that is a fiducial level, and viewing the reflection in it of the webs in the focal plane of the object glass. The distance from the web to its image involves the fault of level in the axis, which can thus be measured and applied to the observations. For field work a smaller reversible instrument is used, in which the axis is first levelled with the help of a spirit level and half-way through the observation the pivots are lifted from their bearings and reversed east and west This seems to give more consistent results than the other method, allowance being made for the lower telescopic power of the portable instrument. But the matter is obscure Further sources of error arise in registering the apparent time of transit. (*See* CHRONOGRAPH) In the end the

best determinations of clock error are much less consistent than the going of the best clocks. Yet the former must be treated as primary sources and the latter subordinated to them. This is a matter of considerable delicacy, for the primary data, besides having erratic features, are also irregularly spaced owing to weather conditions We must take a considerable body of primary determinations, and use the going of the clock to detect and reject their erratic features, before we use the mean run so found in order to assign the error of the clock. This work cannot be done without the exercise of judgment, and, according to their experience, different persons exercise their judgment differently. The result is seen in the comparison of time as determined at different observatories, a comparison that has been made possible with accuracy and simplicity by means of wireless time signals. If the times differed by constant amounts it could be ascribed to an error in the reputed longitudes. But they do not. They vary rather irregularly by quantities of the order of 0·1sec, even 0·2sec., which are perhaps not very large, but are much larger than is tolerated in any other region of astronomy, and much larger than the methods would lead one to expect.

Time measurement, being a problem concerning the phase of the earth's rotation, is eminently a matter for international regulation. It is inconvenient for states to use local time strictly, and a system of zones has been devised and is accepted by most civilized states, whereby within each zone the same mean time rules, but changes abruptly by one whole hour, or half an hour in some cases, at its borders. Thus the local time at Washington observatory is 5h 8m 16s. late on Greenwich, but the mean time kept is 5h. slow precisely. Since mean time is in any case a constructed time, not an observed one, no difficulty is introduced by this convention.

Some other agreements are wanted. Till 1925 Greenwich mean time commenced at noon; from the beginning of that year the meaning of the term was changed so that the reckoning commenced at the previous midnight and the hours 0–24 agreed with those reckoned for civil time. Others have adopted the term "universal time" to describe exactly the same system, so that there are now three designations current for a single scheme. A further convention regulates the "date line," in travelling across which a calendar day is dropped from the reckoning in passing eastward, or is added in passing westward. The line is arbitrary; it runs for the most part along the 180th meridian, but deviates to the east to include Fiji and Tonga with Australasia and to the west to include the Aleutian Islands with the continent of North America.

Wireless Signals.—A new era has been introduced into the determination of time by wireless telegraphy Local time is required for two purposes, first by observatories, in the form of local sidereal time, in order to set the telescopes upon any catalogued object on the sky, and second by an explorer or sailor in order to construct local mean time and to determine the longitude by comparison with Greenwich mean time, which he is supposed to read from his chronometer. Time signals are now used, originating in some well-equipped central observatory, where the full care that is necessary can be given, they are issued as wireless signals from a large number of stations distributed over the world. Received at any fixed observatory, of known longitude, a short calculation gives the local sidereal time and abolishes the necessity of observing it directly; while for a traveller who desires to determine his longitude, the signal supplies a continuous check upon the rate of his chronometer and saves the uncertainties of prolonged extrapolation. Still more important from the point of view of systematic science is the power conveyed of comparing the determinations of time at different observatories continuously with one another, by receiving at any point the signals from different sources, or by receiving at different observatories any one arbitrary signal, and afterwards comparing the results. As already remarked, the results are in poor accord with one another; it would be an important advance if a large improvement of them should result. The faults are now visible and that is the first step towards removing them. The gain would appear first merely as a closer co-ordination of instrumental results, taken under different circumstances of place and time, but could not fail to result ultimately in increased certainty of prediction. At the present stage the investigation figures as a co-ordinated attempt to improve the determination of longitudes.

International regulation of astronomical questions is centred in the International Astronomical Union (I.A.U.), a post-war organization formed at Brussels in 1919, in which a number of earlier conventions were assembled in connection with the International Research Council and operating through the principal research institution of each adherent country. Perhaps the most energetic and fruitful work on special problems is still done by the initiative of individual observatories, but the task is furthered in many ways by the committee created by the I.A.U. Two of these committees have special reference to the subject treated here, the Committee on Longitudes by Wireless Telegraphy, and the International Time Commission. The former has been organized to execute a scheme of world longitudes, by the issue of time signals, in some cases specially designed, from the powerful stations at Bordeaux, Nauen, Saigon (French Indo-China), Annapolis (Maryland), Honolulu, and others, and the determination of their times of receipt at as large a number of observing stations as possible. In a preliminary explanation in 1926 upward of 40 observatories took part; the results are voluminous, and are not yet (1928) fully discussed in co-ordination with one another, but enough has appeared to prove that a much increased precision of longitude determination has been attained; thus, replacing the rather crude discrepancies that used formerly to occur, we find that the time required for the passage of wireless signals across the Atlantic, about ·02sec., appears as a clearly measurable correction in all the better series. The International Time Commission was designed in a more general way to organize the issue of wireless time signals suitable for all users, to receive those that were issued, and to standardize such work generally. Its bureau is at the observatory of Paris, and in the issue of signals it works in conjunction with the stations, military and civil, controlled by the French Government.

For the standard data regarding precession and the motion of the earth round the sun *see* S. Newcomb, "Tables of the Motion of the Earth," vol. vi. (1898), and "Determination of the Precessional Constant," vol. viii. (1905) in "Astronomical Papers" of the *American Ephemeris*. Quoting those relevant to this article, we have

Tropical year	365·24220 mean solar days
Sidereal year	365·25636 mean solar days
General precession in one tropical year	50·2453″ (epoch 1900)

The general precession is compounded by taking the luni-solar precession, less the regressive motion of the ecliptic itself (12·31″ per century). The luni-solar precession varies in proportion with the cosine of the obliquity of the ecliptic.

From the length of the tropical year we deduce 1 mean solar day = 24h. 3m. 56·5554s., sidereal

1 sidereal day = 24h 3m. 55·9095s., solar

TIME SALES: *see* Instalment Selling.

TIMGAD, a ruined city 23 m. S.E of Batna in the department of Constantine, Algeria. Timgad, the Thamugas of the Romans, was built on the lower slopes of the northern side of the Aures

Mountains, and was situated at the intersection of six roads. It was traversed by two main streets, the Cardo Maximus running north and south, and the Decumanus Maximus east and west. The residential part of the town was on a lower level than the capitol and most of the other public buildings. The ruins of the capitol occupy a prominent position in the south-west of the city. Some of the columns of the façade (which are of the Corinthian order and 45 ft. high) have been re-erected. The dimensions of the capitol correspond with those of the Pantheon at Rome. Immediately north of the capitol are the remains of a large market; to the east are the ruins of the forum, basilica and theatre. The auditorium of the theatre, which held nearly 4,000 persons, is complete A little west of the theatre are baths, containing paved and mosaic floors in perfect preservation. Ruins of other and larger thermae are found in all four quarters of the city, those on the north being very extensive

Across the Decumanus Maximus just north-east of the market is the arch of Trajan—still erect, and restored in 1900. The arch is of the Corinthian order, and has three openings, the central one being 11 ft. wide. Each façade has four fluted columns 19 ft. high. The chief material used in building the arch was sandstone. The fluted columns are of fine white limestone and smaller columns are of coloured marble At the other (eastern) end of the street are the remains of another triumphal arch West of the capitol are the ruins of a large church, a square building with circular apse, built in the 7th century. There are also remains of six other churches. About 400 yd. south of the city, the walls nearly entire, is a ruined citadel, a quadrangular building 360 ft by 295 ft., with eight towers It was built (or rebuilt) by the Byzantine army in the 6th century Near the northern thermae is the house of the director of the excavations and a museum containing small objects found in the ruins

Numerous inscriptions have been found on the ruins, and from them many events in the history of Thamugas have been learnt. In the year A D. 100 the emperor Trajan gave orders to build a city on the site of a fortified post on the road between Theveste and Lambaesis. This city, called Colonia Marciana Traiana Thamugas (Marciana in honour of Trajan's sister) appears from the inscriptions to have been completed, as far as the principal buildings were concerned, in seventeen years. In the 3rd century Thamugas became a centre of Christian activity, and in the next century espoused the cause of the Donatists. The city declined in importance after the Vandal invasion in the 5th century, and was found in a ruinous condition by the Byzantine general Solomon, who occupied it A D 535. It is believed that the Berbers from the neighbouring mountains destroyed the city, hoping thus to prevent it being used as a stronghold from which to harry them Thamugas was, however, repeopled, and in the 7th century was a Christian city. After the defeat of Gregorius, governor of Africa, by the Arabs in 647, Thamugas passes from history.

After centuries of neglect James Bruce, the African traveller, visited the spot (1765), made careful drawings of the monuments and deciphered some of the inscriptions. Bruce was followed, more than a century later (1875), by Sir R. Lambert Playfair, British consul-general at Algiers, and soon afterwards (1875–1876) Professor Masqueray published a report on the state of the ruins. Since 1881 Thamugas has been systematically explored, and the ruins excavated under the direction of the *Service des monuments historiques*. Among the objects discovered are a series of standard measures—five cavities in a stone slab.

Seventeen miles west of Timgad, on the site of the Roman city Lambaesis, is Lambessa (*q.v.*).

See G. Boeswillwald, R. Cagnat and A. Ballu, *Timgad, une cité africaine sous l'empire romain;* and A. Ballu, *Guide illustré de Timgad* (Paris, 1903).

TIMGUR: *see* NUBA.

TIMISOARA (formerly TEMESVAR), a city of western Rumania, capital of the department of Timiş Torontal. Pop. (1928) 58,600, largely Magyar. It lies on the navigable Béga canal and on the river Béga, and consists of the inner town, formerly strongly fortified, and of four outlying suburbs, the intervening space, formerly the glacis, having been laid out in parks. Timisoara is the seat of a Roman Catholic and a Greek Orthodox bishop. Amongst its principal buildings are the Roman Catholic cathedral, built (1735–57) by Maria Theresa; the Greek Orthodox cathedral; a castle built by John Hunyady in 1442, now used as an arsenal; the town and county hall, the museum and large barracks In the principal square rises a Gothic column, 60 ft. high, erected by the emperor Francis Joseph in 1851 to commemorate the successful resistance of the town to the siege of 107 days laid by the Hungarian revolutionary army in 1849. Timisoara is a centre of commerce

Timisoara is an old town, and although destroyed by the Tatars in 1242, it was a populous place at the beginning of the 14th century, and was strongly fortified by King Charles Robert of Anjou, who resided there several years. The Hunyady family had also their residence there. In 1514 the peasant leader, Stephan Dozsa, was defeated by the Transylvanian voivod, John Zápolya, near Timisoara, captured and executed. It was taken by the Turks in 1552, and recovered by Prince Eugene of Savoy in 1716. After this it grew steadily in importance, serving as the capital of the whole Banat. It was again besieged by the Hungarians in 1849, and occupied by Serbia in 1919, but ultimately allotted to Rumania.

TIMMINS, the principal town in the Porcupine gold-mining area in northern Ontario, Canada, 268 m north of North Bay, on the Temiskaming and Northern Ontario railway It is the centre of the most important gold-mining area in Canada, where in 1926 the output of gold amounted to $23,810,600 The most outstanding mine in the district is the Hollinger, the third largest gold-mine in the world Timmins has grown rapidly from a population of 3,843 in 1921 to the 1927 estimate of 15,000

TIMNE, a long-headed people of medium stature, skilled traders, in Sierra Leone, whose language is related to Landuman and Limba Their paramount chief traces his genealogy back to the beginning of the 16th century Dowry and dower are both customary. Descent is patrilineal, and there is both family and personal property, the first inherited by the brother or nephew, the second by the son. The Timne are organized in clans

See N. W. Thomas, *Anthropological Report on Sierra Leone* (1916).

TIMOLEON (*c.* 411–*c.* 337 B.C), of Corinth, Greek statesman and general As the champion of Greece against Carthage he is closely connected with the history of Sicily, especially Syracuse (*q v.*) He was driven into exile for 20 years by the anger of his family at his acquiescence in the death of his brother Timophanes, who had made himself tyrant In 344 (Plutarch, Diodorus gives 343–342) he was chosen to go to Syracuse in answer to an appeal to Corinth for help against factions within and the Carthaginians without. He landed at Tauromenium (Taormina) and first attacked Hicetas, tyrant of Leontini, who was master of Syracuse at the time. Carthage first supported Hicetas, then abandoned him, and he was besieged in Leontini and surrendered Timoleon then reorganized Syracuse on the basis of the constitution of Diocles, and introduced new settlers from Greece About 340 Hicetas was reinforced by a new army from Carthage, which Timoleon defeated on the Crimissus, and a renewed attempt ended in Hicetas' final defeat and death in 338 A treaty was concluded confirming the dominion of Carthage to west of the Halycus. Timoleon then (337–336) retired into private life He became blind some time before his death, but persisted in attending the assembly and giving his opinion, which was usually accepted as a unanimous vote. He was buried at the cost of the citizens of Syracuse, who erected a monument to his memory in their market-place, and a gymnasium called Timoleonteum.

Lives by Plutarch and Cornelius Nepos; *see* also Diod. Sic xvi. 65–90; monograph by J. F Arnoldt (1850), which contains an exhaustive examination of the authorities; also SICILY: *History;* and SYRACUSE, with works quoted.
